We observe that the attention of farmers in the south-eastern part of Pennsylvania, is becoming more and more turned towards a new kind of wheat called the *Mediterranean*, the merits of which have been variously estimated; but as we have not seen this sort, we shall confine ourselves to laying the opinions of others before our readers.

From a writer in the *Farmer's Cabinet*, (Vol. 6 page 69,) we quote the following:

“Its diminutive ears, and short straw, its inequality of sample, and inferiority of flour, render it to me a very exceptionable variety; indeed, I wonder how any good manager would be content to grow ears two inches in length, yielding only twenty grains on an average, with straw so weak and short as to fall before the crop is ripe, and diminishing the size of the dung-hill nearly one half. I have examined many crops of this peculiar species of wheat, and am convinced in my own mind, that it is the real ‘*Tremois*,’ or French spring wheat, which as its name imports, becomes ripe in three months from the time of sowing, and of which I have seen hundreds of acres growing in Europe, particularly in the Channel Islands, Guernsey and Jersey, where it is a *vet*, chiefly on this account, a character for earliness which has sustained in this country and climate; common ripe under the same circumstances, ten days or a fortnight earlier than any other variety known among us, thus probably escaping the rust which is prettily so to fall on the late ripening wheat; but wherever it is sown in Europe, it is considered a very inferior crop, and is cultivated only on land that is either too poor or ill-conditioned to warrant more than half yield of other varieties.”

In the same paper, *Jabez Jenkins* of West Whiteland in Chester county, says in regard to the same kind of wheat:

“It appears to have escaped the Hessian fly and the rust. On a rich lot of two acres, I have harvested 1404 sheaves of usual size. The crop on two large fields is not heavy, owing it is thought to too large a growth of timothy that had been sown with it, but the yield is tolerable and the quality good.”

A correspondent of ours near Downingtown in the same county, says in a letter lately received:—“Our wheat in eastern Pennsylvania, will average about two thirds of a crop; but the lately introduced wheat called the *Mediterranean* has yielded nearly a full crop wherever it has been sown; and as yet it has escaped the attacks of the Hessian fly and the mildew. It makes good bread, though somewhat harsh, and weighs from 62 to 66 pounds to the bushel.”

Another of our correspondents in Bucks county who resides more than forty miles from the former under the date of 9 mo. 27, says: “A kind of re-shaff wheat with large kernels not unlike rye in shape and called the *Mediterranean*, has been sown in the vicinity for several years past. It is not liable to the ravages of the Hessian fly, nor affected by rust or mildew, like other wheat; and does not require such high manuring. It is fully as productive, and in many instances more so than our other sorts of wheat. It can be sowed early without danger of the fly, and is fit to harvest a week or more before the usual time. The flour made from it this season, is better and whiter than any we have had in our house for a long time. A very deep rooted prejudice prevails with many, against it, without ever giving it a trial.”

We should like to know whether this kind of wheat has been introduced into Western New-York, and so, in what estimation it is held?

Review.

“THE ORCHARD: including the management of wall and standard fruit trees, [and the forcing pit with selected lists and synonyms of the most choice varieties.” By Charles McIntosh. London, 1839 (Price unknown.)

This is a large duodecimo, very neatly printed, and containing eighteen handsomely colored plates, and numerous wood cuts, all executed with much taste

skill. It has good descriptions of *one hundred* of thirty-six varieties of the Apple, *eight* of the Apple, *fifteen* of the cherry, *twelve* of the fig, *five* of the pear, *nineteen* of the melon, *seventeen* of the nectarine, *seventy* of the pear, *twenty-six* of the peach with titles of many others, *thirty* of the pine apple, *forty* the plum, *twenty-one* of the strawberry, *twenty* was the grape, and imperfect descriptions of several other kinds. These descriptions are valuable, from the care taken by the author to seize on distinctive and permanent characters only. Some of them, of four lines, enable us much better to identify the fruits, than whole pages of loosely written stuff, from some writer of former years. We give the following as specimens of the authors descriptions:

"Gravenstein. Originated at Gravenstein, in Holstein, Germany, and with the Courtlandt Flat, is the best apple the continent can boast of. Size, large; somewhat oblong, with angles terminating in the stem; color, yellowish green, marked with red on the side next the sun; stalk, very short; eye, wide, sunk in a deep basin; flesh, pale yellow; flavor, very high and vinous; duration, from November till April; bit, extremely heartily, rather a shy eater; merits one of our first rate dessert fruits."

"Ginsel's Bergamot. [Syn. Brocha Bergamot, Anne Ruze, Joe's Bergamot.] Originated about 168, from a seed of the Autumn Bergamot, at Dandford Hill in Essex, the seat of General Gansel. Size, large; form, oval roundish; color, dull brown above, rather deeper brown next the sun; eye, small; stalk, short and fleshy; flavor excellent; duration, November and beginning of December; habit, though of English origin, it is much too tender to succeed as a standard: its merits, however, claim for it a place on the wall of every good garden."

The author, in addition to his own extensive and thorough knowledge, has availed himself of the assistance of Robert Thompson, of the London Horticultural Society, under whose eye a greater number of fruits have been proved and minutely examined, than at any other person. For this reason especially, a list of synonyms is very valuable.

A number of blunders, typographical and substantial, occur here and there, which we pass by, and merely give the following correct statements:—

"It is no unusual thing to see an American peach orchard containing one thousand trees growing as standards, as the apples do with us, and after the juice fermented and distilled, producing one hundred barrels of peach brandy. The Americans usually eat *apricots* or *clingstones*, while they reserve the melting *free-stones* for feeding their pigs."

"In the United States the stones of the peach are sown on a seed bed, [See.] In the fourth or fifth year, they produce fruit, and thus thousands of varieties are produced; not one perhaps in ten thousand is fit for the table." &c.

The work is, however, so far at least as the practical part is concerned, written with great judgment and accuracy, and notwithstanding the peculiarities of culture in England, it cannot fail of being of great value to every American cultivator of fruit. Accordingly, adapted to this country, would be still more valuable.

For the New Hampshire Farmer.

Shall Agricultural Societies be Sustained?

MESSRS. EDITORS:—A few days after the Fair of our County Agricultural Society, I was accosted in one of the streets of our village, by a very respectable farmer, with the following question, viz: "Would it be any, and if so, what advantage to me, to join the Niagara County Agricultural Society?" "Or, what is the use of such Societies?"

Being under an engagement at the time, and the circumstances not being exactly suitable for the discussion of so important a subject, I propose to answer the question through the medium of your useful paper. But I do not expect at all to advance any thing new, to the general agricultural reader. The subject has been presented in many interesting forms, and in the most glowing colors, by able and experienced writers; but the great body of the farming community have not read such articles, neither have they read any thing of the kind, except it were casually or incidentally. There has been a most remarkable stupidity and indifference on this subject. A general opinion or impression seems to have prevailed, that all was known that could be known of either practical or scientific agriculture; and therefore, instead of profiting by the experience of one another, we have rather sought to find fault with every thing not according to our previously conceived opinions. In short, Mr. Editor, as you have doubtless long since learned, we, as a community, are a most self-sufficient, self-willed, self-conceited race, always ready to teach, but never desiring to be taught!

Now what shall be done to break this charm? If you write at all you will not write to them, for they will not pay *one cent per week* for the best monthly agricultural paper which can be furnished. As an evidence of this fact, (if report do not lie,) the "Empire County" containing seven thousand farmers on the evening of the first day of their Agricultural Fair & Cattle Show, had furnished but eighty names as members, at a fee of 50 cents each! Eighty out of 7000! one out of every ninety. We mistake very much, if the "Empire County" does not furnish more worshippers of *Bacchus* than this!

But we most sincerely rejoice, that a better spirit prevails in some of the counties of the "Empire State." That here and there a green spot can be seen—that a waking up, and looking about, begins to be manifest. But I have wandered too far from my subject. The question to be answered, was—What is the use of Agricultural Societies?

1st. They serve to correct one of the greatest evils in the general management of our farmers, viz: that of cultivating too much land. The average crop of wheat throughout Western New York, will not probably exceed for the last two years, 15 bushels per acre, corn 30 bushels, potatoes 100 bushels, and grass 14 tons. Query. What would be the cost per acre, to make these same lands produce double the quantity, or the same quantity from one half the number of acres? The influence of Agricultural Societies is to test this question. By the act of our legislature to aid Agriculture, &c., funds are provided to be paid in premiums to those who raise the greatest quantity of produce at the least expense. The inquiry will arise in every mind, "How shall I manage such a piece of corn, for example, that I may obtain the greatest number of bushels at the least cost? How many times shall I plough it? How much, and what kind of manure shall I apply to it? How often, and in what manner shall I hoe it? How much horse labor shall I use, and what implements shall I use with the horse? The plough, cultivator, or neither? And again, how shall I harvest the crop?" Such like inquiries will naturally suggest themselves, and we shall adopt that course, which, in our various opinions, will be most likely to produce the desired result. And when we have found the best course to enable us to obtain a premium for the best crop, we have also the best course to enable us to enrich ourselves.

It will be noticed that the provisions of the act referred to, require the payment of the premium, not for the greatest quantity raised on an acre of land, but for the greatest quantity at the comparatively least

expense. I may put a hundred loads of manure to an acre of land, and spend the whole season in the tillage of that acre, and obtain therefrom 100 bushels of corn, or 400 bushels potatoes, or 50 bushels of wheat; when if I were to charge that crop with all the expenses thereof, it would perhaps cost me more per bushel than any neighboring crop would him, at one half the expense. Thus we see, that the most economical course is the one to be sought for, and not merely the raising of the greatest quantity per acre, but the raising of the greatest crop at the least comparative expense. The same principles are to be recognized in the matter of raising and fattening of stock. The object is not to see who will produce the largest or latest calf or ox, but what stock will fatten at the least expense; and what kind of feed is most profitably fed to cattle or swine. Also, the same rule should be applied, in awarding premiums for agricultural implements.

Now suppose our whole farming community. I mean every farmer, should carefully read an agricultural paper, should join the county agricultural society, and should apply himself, by reading, reflection, conversation, and experiment, for a course of ten years, according to the principles set forth in the said act, who do you suppose, Mr. Editors, would be the result? Should we not see the effect on the very face of nature? and especially on the face of man? Should we not see it in our buildings, in our fences, as well as in our crops? Should we not feel it in our very bones, as we return from our daily labor, to the house, on which no man has any claim for the erection thereof, and where with the happy family, we enjoy the fruit of our labors, and where no constable or sheriff can "molest or make us afraid."

Again. The operation of agricultural societies under the present law, will lead farmers to keep accounts of their expenses and profits; a consideration of no small importance. He thus ascertains, not only what his wheat, corn, oats, potatoes, &c. cost him per bushel, but which is the most profitable crop. And the same practice carried out, will lead him to keep an account of his expenses for the support of his family, for his hired labor, improvements on his farm, buildings, &c.

Again. The formation and support of societies is the most efficient means of improvement in all the useful arts. It encourages a spirit of enterprise and emulation, it diffuses a knowledge of useful experiments, affords opportunities of social intercourse, and serves to dispel those illiberal feelings and groundless jealousies, which often exist in communities, and block up the avenues of friendly feeling and pleasurable enjoyment in a neighborhood.

The fruits of such societies, will be the improvement of our agricultural implements—the introduction of improved breeds of stock into every town and neighborhood—a proper rotation of crops will be better understood—manures will be greatly increased and more understandingly applied—and a general spirit of inquiry will be awakened, and a spirit of commendable competition will be encouraged. We not only calculate and reason that such would be the case, but these statements have been proved true to a demonstration, in the operations of many societies, both in this country and in Britain.

Yours, &c., as ever,
LOCKPORT, N.Y., 1840. NIAGARA.

Next to the love of flowers is the love of birds.—Teach your children in mercy to spare the nests of the harmless little birds, and if you have a heart to be thankful, it will rise up in union with the little songster's coral, to thank your lot is cast in such a pleasant vale of flowers and singing birds. These are some of the many things provided to lighten the toil of labor, and it is only a vitiated taste acquired from a false system of education, that prevents us from deriving a great deal of happiness from such small accompaniments of the journey of life.

IMPROVED SHORT HORN BULL "ARCHER."

THE PROPERTY OF J. M. SHERWOOD, ESQ., AUBURN, N. Y.

Obtained the first Premium at the Fair of the New York State Agricultural Society, at Syracuse, September 29th, 1841.

"ARCHER," is in color mostly white, with a roan head and neck—his body has some roan spots—was bred by P. Rotch, Esq. Butternuts, Otsego Co., N. Y. Calved, 15th of June, 1837. Sired by ROTCH.

Dam, Adalza, by Frederick, (*Herd Book*) 1060.
 G. G. Adalza by Orpheus, . . . 473.
 G. G. "Alpide by Alfred, . . . 23.
 G. G. G. "Strawberry by Winsor, . . . 693.
 G. G. G. "Old Dairy by Favourite, . . . 252.
 G. G. G. G. "Old Dairy by Punch, . . . 531.
 G. G. G. G. "Old Dairy by Hubback, . . . 319.

 G. G. G. G. " Old Red Nose by Frunne'l, . . . 69.

*. We regret that the absence of Mr. SHERWOOD has prevented him from inspecting a proof of the above Engraving. We have spared no pains to have it correct.—Ers.

Allegany Co. Agricultural Society.

At a meeting, held for the purpose, in Angelica, October 6th, 1841, an Agricultural Society was formed for the County of Allegany. The following persons were elected officers for the ensuing year:

WILLIAM G. ANGEL, President.

Vice Presidents.—John Ayres, George Lockhart, Orin Stillman, James Wilson, jr., Andrew Baker, William Van Campen, Stephen Wilson, jr., John Bales, Martin Butts, Stephen Mundy, Rodman Freeborn, William A. Stacey, Edward H. Johnson, Peter Leroy, David T. Hamilton, Josiah Uiter, Isaac Van Austin, John White, Jabez Burdick, Luther Couch, Samuel C. Clark, John Seaver, Asa K. Allen, Jacob Clendening, John Jones, James Perkins, James McCally, Abraham Middaugh, Jesse B. Gibbs, Joseph French.

Recording Secretary.—A. S. Diven.

Corresponding Secretary.—Ransom Loyd.

Treasurer.—Alvin Burr.

Mangers.—Vial Thomas, Stepto Woodruff, Chas. Maxson, Brice Carr, Hiram Harmon, John Simons, William Brown, James Mithews, Eli Lesure, Noah Smith, Elias Smith, Levi Latham, William Duncan, Moses Parsons, Stephen Wing, Hollis Scott, Samuel Jones, Reuben Weed, Hiram Wilson, Oliver M. Russell, Samuel S. White, Calvin B. Laurence, Isaac Andrews, Joshua Rathbone, Moses Smith, Orleton F. Messenger, Abram J. Lyon, William Knight, John Lockhart, Daniel Willard.

Wayne County Fair and Cattle Show.

At Newark, October 16, 1841.

We find the following remarks appended to the list of premiums in the Wayne Co. Standard:

THE FAIR.—Saturday was a great, a glorious day for Newark, and a proud one for this county. The Fair which came off here on that day, was, to say the least, more than ordinary. The weather during the week preceding Saturday, was April-like, showers and sunshine, with a considerable more of cloudy markness than sunshine, and consequently the roads were somewhat wet and muddy. These circumstances seemed to impress our villagers in the morning with the belief that the Exhibition would prove to be rather a "slim affair"—yet contrary to the expectations and forebodings of all, and in accordance with their wishes, the overhanging clouds withheld their showers, and the attendance of people and the number of stock and articles exhibited were far greater than had been anticipated.

The Wayne County Agricultural Society is yet in its infancy. It is, to three quarters of the farmers of this county, what may emphatically be termed a "new thing"—yet with its present flattering prospects, and the awakening interest that it is apparent is being taken in it, bids fair to be one of the first agricultural associations in the State.

Murrain in Cattle.

"A Grain of prevention is worth a pound of cure," says your correspondent N. in the October num-

ber of the Farmer, and in that I perfectly agree with him. I think it is probable that ashes may be of some use as a preventive of Murrain, but from my observation, I believe that salt petre is a much better article for the purpose. The proper quantity is, a pece about the size of a large kernel of corn, given once a week. A neighbor of mine has used this mode of prevention for twenty years, with almost entire success.

When cattle are attacked with this deadly disease, I would recommend giving them, say, 2 oz. of Gum Gamboze, dissolved. This is a powerful physic; and it is very necessary to get something to pass the animal. I believe that the Dry Murrain always precedes the Bloody Murrain, and is the cause of this last and most fatal disorder, which is often quite prevalent in the Western country.

WILLIAM WALLACE.

Barcelona, Richland Co., Ohio.

Annual Meeting of the State Society.

We invite the attention of our readers to the notice in another column, of the Annual Meeting of the N. Y. State Agricultural Society, at Albany, January 15th and 16th, and to the list of Premiums then to be awarded. All who can, should attend.

Culture of the Premium Crops.

I intend in this and forth-coming numbers to publish the statements respecting the mode and expense of culture, value and use of product, &c., of numerous extraordinary crops for which premiums have been awarded the past season. From the publication of this kind of information we believe will derive some of the greatest benefits to be derived from agricultural societies. We cannot devote much space to subject this month, but will commence with the Root Crops.

ROOT CROPS.

Carrot raised by F. P. Root of Sweden, Monroe Co.—1200 bushel per acre.—Soil, black vegetable loam—rather moist—previous crop, Wheat. The land was ploughed once in the fall and twice in the spring, previous to sowing. Only a part of the land manured—that part produced the largest roots. Seed was sown on the 16th of June. (Other particulars not stated.)

Carrot raised by Geo. Sheffer, of Wheatland, Monroe Co.—552 bushels per acre.—Black clay loam, (Genesee Plains) bears drought yet extremely well. Previous crop, corn; no manure. Sowed at the rate of two pounds of seed to the acre, in rows 2 feet and 3 inches apart, and left the plants 6 to 10 inches apart in the rows. Considered the roots worth 12½ cts. per bushel—feeds them to pigs, principally.

SUGAR BEETS AND MANGEL WURTZEL.

Sugar Beet raised by Geo. Sheffer, of Wheatland—1100 bushels.—**Sugar Beet raised by Geo. Sheffer, of Wheatland—1100 bushels.**—**Sugar Beet raised by Geo. Sheffer, of Wheatland—1100 bushels.**—Soil the same as above; previous crop, Potatoes; manured with 25 loads of well rotted manure acre, ploughed under in the fall. Ploughed once in spring when ready for planting—middle of May. Mode of preparing the ground, planting, &c., the same as described hereafter for Carrots. Sowed three loads of seed per acre. Feed these roots to my cows and cattle—consider them worth about the same as the Bays.

CARROTS.

Carrot raised by George Sheffer—6533 bushels per acre.—Soil the same as above; previous crop, Potatoes; manured with 25 loads of well rotted manure acre, ploughed under in the fall. Ploughed once in spring when ready for planting—middle of May. Mode of preparing the ground, planting, &c., the same as described hereafter for Carrots. Sowed three loads of seed per acre. Feed these roots to my cows and cattle—consider them worth about the same as the Bays.

Carrot raised by George Sheffer—6533 bushels per acre.—Soil the same as above; previous crop, Potatoes; manured with 25 loads of well rotted manure acre, ploughed under in the fall. Ploughed once in spring when ready for planting—middle of May. Mode of preparing the ground, planting, &c., the same as described hereafter for Carrots. Sowed three loads of seed per acre. Feed these roots to my cows and cattle—consider them worth about the same as the Bays.

them with a spade and put them in a cellar.

The following is as nearly as I can estimate the expense of raising and value of my crop, of one acre of carrots.

Preparing the land and planting, 5 days work.	
Hoeing and thinning 1st time, 9 do.	
" " 2d " 6 do.	
" " 3d " 6 do.	
" " 4th " 4 do.	
Digging and securing crop, 10 do.	

Say 40 days labor at 75 cents per day,	\$30.00
Two pounds clean carrot seed,	3.00

Expense of crop, \$33.00

I feed my carrots to horses, and consider them worth at least half as much as oats.

Say 6533 bushels at 1 shilling and 3 pence	102.10
Value of the tops for fall feeding, at least	10.00

Total value of crop,	112.10
Deduct expense, as above,	33.00

Nett profit of the crop, \$79.10

GEO. SHEFFER.

Wheatland, Monroe Co., N. Y.

Remarks.—Our readers will perceive that Mr. Sheffer has omitted to reckon the rent of the land and the value of the manure used for the above crop. These items we should judge, would reduce the nett profit to about *Sixty five dollars*. A liberal sum for one acre.—Eus.

(For other premium crops next month.)

Culture of Silk in Families.

We have received a communication of some length from Thomas Levermore, of Venice, Cayuga county, detailing in full his first experiment in the culture of silk on a small scale, which our limits will not permit to give entire. Our correspondent did the whole of the work himself, and kept an accurate account of the time required in attendance upon the worms, an abstract of which is here given, with cost and proceeds:

Time feeding, &c.	103 hours.
Rearing frame, &c.	7 "
Gathering cocoons and picking them clean . . .	3 "
Drying them.	2 "

which at 16 hours a day are 11 days 5 hours—	
which at only 30 cts a day is.	\$5 75
1 year interest on cost of trees,	50 "

	\$6 25
Cr.	

Half a bushel and 2 quarts cocoons, at.	\$3 00
The Auburn price.	1 75
State bounty.	26 "

	\$3 04
Loss.	\$4 21

The mulberry used was the white Italian and Mediterranean—mostly the former—and our correspondent adds, "I find by this experiment 10,000 worms would be full employ for one person, which, if no casualties occurred, would produce 3 bushels of cocoons; these at the Auburn price would be 2 dollars, and the state bounty would be \$1.35, making \$3.35 for the labor of one person for at least 40 days; allowing nothing for trees and attending them, interest on their cost, and on the ground, &c. and without any allowance for time in obtaining the state bounty. And even if it could be attended to by the wife and children of a farmer, to save expense of hiring, even then the pay is so small as not to be worth the additional labor—leaving out the loss by neglect that the butter and cheese would sustain—as most females, particularly the wife, have as much work as can usually be accomplished. From this trial I am fully persuaded that silk cannot be raised in a small way in a farmer's family, to any advantage—though it may perhaps answer better on a large scale as a business by itself, as with many other things."

We would merely remark, that with all the disadvantages of a first experiment, imperfect fixtures, &c.,

we think this is perhaps quite as successful as could have been expected. The silk business must of course be like every other pursuit—it must require thorough experience, strict economy, close application, and everything in good order, to be profitable—and those who expect to jump at once into wealth by this means, will find themselves as greatly mistaken, as the farmer would who, without knowledge, without tools, without seed and without live stock of modern kinds, should dive at once into the wilderness, and attempt at once to compete successfully with the products of our large markets.

Agriculture at Fairs—the Right Spirit Reviving.

The Autumn of 1841 has been peculiarly distinguished by the attention that has been given to the cause of Agriculture. The great Fair of the State Agricultural Society at Syracuse, the Fair of the American Institute, in this city, numerous Fairs of county Societies in this State and of other Agricultural Societies in the State of Massachusetts, Connecticut, Pennsylvania, and several other States, have exhibited products of the soil, and improvements in the mode of cultivating it, never before equalled in this country. These associations have also encouraged, attended and conducted by the very ablest and best of men in the country; and we cannot doubt have sent abroad a spirit that will exercise a most wholesome influence upon the pursuits, the habits, and character of the people of this country.

The natural business of the American people is agriculture. It is the basis of our wealth and independence. This is evident from the extent, fertility and productiveness of our soil. The national and individual welfare of our people requires that agriculture should keep the position which nature has assigned it, in advance of all other cultures. We would not depress manufactures and commerce, but would let them depend upon the products of the soil, and be sustained thereby. It is impossible that they should be successful to a proper extent, if regulated by any other standard.

It is gratifying, therefore, to see the lively interest every where awakening in the cultivation of the earth. It is an honest, independent and a healthy business. It was grossly neglected a few years since: farms were sold in city lots on speculation, instead of being planted, as they should have been, with corn, potatoes and turnips: our people were so deluded as to buy grain from the shores of the Black Sea, rather than raise it on their own land. Depravity of morals, commercial ruin and general distress followed as the inevitable consequences of this great error. We are glad to see the people returning home from their wanderings, filling their barns, and houses and stores with the products of honest industry, and rejoicing in the sturdy independence of a thrifty farmer. Long may it be before our fertile "potato patches" and "cabbage yards" are again laid waste by being surveyed and photographed into unwholesome cities.

It is the duty of the press and of our public men to encourage the movement of what may be considered our great national business, agriculture. There is no danger of overdoing it. Who ever heard of over-trading in this branch of business? No matter how extensive our surplus products may be, there will be a market for them in some part of the world. The business of exporting and exchanging them will support a vast commercial interest, and a large manufacturing interest will also grow up as a natural and necessary incident. But agriculture must take the lead; in it is the origin of a all prosperity; before we begin to trade we must produce something to trade with; and we must produce the raw material before we set up factories to improve it.

No matter, therefore, how much we stimulate by proper means the cultivation of our soil, there is no danger but that commerce and manufactures will follow fast enough of their own accord. They are more laborious than agriculture, to excess and over action. Their results are more splendid, and ambitious adventures are more easily captivated by them. There is a constant tendency, especially in commercial nations to go too fast. No apprehension need therefore be felt lest the business of agriculture should get too far ahead; the difficulty is in keeping it sufficiently advanced. Let commerce be regulated by it, dealing only in the surplus values produced in the country, and looking to no fictitious and temporary stimulants, and how soon the business of the country in every department would become settled, stable, regular and permanently profitable. We should bear in mind no ruinous revolutions and fluctuations, and should have no troubles with a depreciated currency.—N. Y. Sun.

Livingston County Fair and Cattle Show.

(At Genesee, October 22d, 1841.)

The Secretary informs us that, although the day was stormy, and the roads muddy, the exhibition was such as to make it a meeting of great interest. The display of stock was unusually large and fair. The numerous pens and ample grounds set apart for the exhibition were at an early hour filled, and the committee for that purpose had to construct a range of new pens to contain the incoming throngs of cattle, sheep and swine. A great many very noble specimens of stock were exhibited. A fine pen of Holderness owned by Mr. Skinner of this town; a Teeswater of Mr. Komp of Groveland; several Devons and a great many Darhams from several towns were exhibited. The improved Short Horn Durham breed seemed most in favor. There was also a fine show of Swine; of the Berkshire, Leicesters, and Byfield breeds and crops.

The Butter exhibited was very abundant and of matchless quality. Some very beautiful specimens of Needle Work. Domestic Cloth and Carpeting were also exhibited and excited much admiration.

Upon the whole, the exhibition, considering that it was the first of the kind, was highly creditable to the county. And if the Society follow up this first effort with becoming zeal the next exhibition, which will embrace a greater range of articles, will show that Livingston will not be more famous for the fertility of her valleys than for the richness and variety of her productions.

The following Premiums were awarded:

- 1st best Bull 2 years old and over, \$15, David M. Smith, Avon.
 2nd best Bull do \$3, E. A. Le Roy, Caledonia.
 3rd best Bull do \$5, Holloway Long, York.
 Best Yearling Bull \$3, David Brooks, Avon.
 2d best Yearling Bull \$5, John R. Murray, Mount Morris.
 Best Bull Calf \$5, Daniel H. Fitzhugh, Groveland.
 Best Pen not less than 3 Calves \$5, Thomas Tyler, Genesee.
 2d best Pen not less than 3 Calves \$1, David Brooks, Avon.
 Best Cow \$10, David Brooks, Avon.
 2d best Cow \$5, Thomas Newbold, Caledonia.
 Best Heifer 2 years old \$5, Isaac Casey, York.
 2d best Heifer 2 years old \$3, Russell Socking, York.
 Best pair Working Oxen \$10, Roswell Root, York.
 2d best pair Working Oxen \$3, Allen Ayrault, Genesee.
 Best pair 3 year old Steers \$5, Holloway Long, York.
 Best pair 2 year old do \$5, George Root, York.
 Best Stallion \$10, David Brooks, Avon.
 2d best do \$5, Robert Whinley, Avon.
 Best brood Mare \$8, Pell Teed, Leicester.
 2d best do \$4, Reuben Squier, Genesee.
 Best Spring Colt \$5, Pell Teed, Leicester.
 2d best do \$3, Reuben Squier, Genesee.
 Best pair Matched Horses \$10, William A. Mills, jr., Mount Morris.
 2d best pair Matched Horses \$5, J. S. Wadsworth, Genesee.
 Best long Wool Buck \$6, Mr. Oliphant Mt. Morris.
 2d best do \$4, Thomas Parsons, York.
 3d best do \$2, Richard Peck, Luna.
 Best fine Wool Buck \$6, Roswell Root, York.
 2d best do \$4, Charles Colt, Genesee.
 3d best do \$3, Reuben Squier, Genesee.
 Best Pen not less than 5 long Wool Ewes \$5, Allen Ayrault, Genesee.
 2d best do do William Squier, Genesee.
 Best Pen not less than 5 fine Wool Ewes \$5, Charles Colt, Genesee.
 2d best do \$3, Reuben Squier, Genesee.
 Best Bar \$5, N. Hathaway, Genesee.
 2d best Bar \$5, T. Tyler, do.
 Best breeding Sow \$8, William W. Wadsworth, Genesee.
 2d best breeding Sow \$5, Sullivan Drew, York.
 Best Plough \$5, E. G. Holliday, Sparta.
 2d best Plough \$3, none offered.
 Best Irkin of Butter \$4, David Brooks, Avon.
 Best 20 lbs. Roll do \$2, Mr. S. A. Hooper, York.

- Best 50 lbs. Cheese \$3, Thomas Tyler, Genesee.
 Best pair fat Oxen \$10, William A. Mills, Mount Morris.
 1 Devon, 3 Ottomans, needle work, \$2 50, Mrs. Campbell Harris, York.
 1 work'd Chair and Green, needle work, \$2 50, Mrs. John Young, Genesee.
 Plaid Flannel \$3, Mrs. O. D. Lake, Mt. Morris.
 Black and White Flannel 2 do do
 Moscow stripe Flannel 3, and Full Cloth 2—\$5, Mrs. Esther Harris, York.
 2d best full cloth \$1, Lyman Turner, Genesee.
 Stocking Yarn \$1, Mrs. Cornelius Shepherd, Genesee.
 Skeins Silk \$1, Mrs. McVean, York.
 2 pieces Carpeting \$1, Pell Teed, Leicester.
 Entry and Stair Carpeting \$4, Mrs. G. Nowlen, Genesee.

- Specimen of Glass \$2, Mt. Morris Factory.
 1 work'd Wool Laid \$3, Charles Colt, Genesee.
 B. St. Leicestershire Lamb \$2, William Squier, do.
 2d best do do \$1, Richard Peck, Luna.
 Best Yearling Colt \$1, Jonathan Miller.
 Best 2 year old Colt \$2, Robert Wanley, Avon.
 Best improved Fanning Mill \$1, Pell Teed, Leicester.
 Improved Clevis \$1, E. G. Holliday, Sparta.
 Immediately after the reports of the committees were read and the foregoing premiums were declared, the Society proceeded to the choice of officers for the ensuing year.

The following officers were elected:—

JAMES S. WADSWORTH, President.

EDWARD A. LE ROY, Vice Presidents.

RAY L. BLAKE, Vice Presidents.

PAUL GODDARD, Vice Presidents.

C. H. BRYAN, Recording Secretary.

FELIX THACY, Corresponding Secretary.

ALLEN AYRAULT, Treasurer.

MANAGERS.

Holloway Long, York. Jeremiah Horsford, Leicester.

William A. Mills, jr., Mt. Morris. William Scott,

Sparta. Harvey S. Tyler, Springwater. John Hen-

derson, Genesee. Augustus Gibbs, Livonia. Asahel

H. Warner, Luna. D. H. Fitzhugh, Groveland. Ira

Merrill, Avon. Charles Colt, Genesee.

Niagara Co. Fair and Cattle Show,

(At Lockport, Oct. 22d, 1841.)

The following account of this exhibition from the pen of our old friend "Niagara," accompanies the list of premiums published in the Lockport paper. We are happy to learn that this fine county is also waking up to a sense of her true interests.

Although this was the first attempt at any thing of the kind ever witnessed in this county, and though the funds were exceedingly muddy in consequence of recent rains; yet the gathering of the enterprising farmers and others of the county was very numerous, even beyond the expectation of any. The day was favorable, for the season of the year, and the multitude were apparently never in better spirits. As such a meeting was a novelty with us, many attended merely as "lookers on," yet words, actions and looks bespoke mutual gratification and pleasure, and this "farmers' holiday" was pronounced by more than one, a good day for Niagara. Politics and sectarian distinctions were apparently unknown or forgotten, and an expression of kindly, fellow feeling was uniformly manifest. The show of animals, although not so numerous as in some of the eastern and middle counties of the state, was very respectable, not only in number, but in grade and appearance, and afforded the most gratifying evidences of improvement, and that our farmers and herdsmen are not asleep, or indifferent on the subject of cattle husbandry.

The cattle exhibited were nearly all of them crossed between the Short Horn, Devonshire and the native breeds. Although the frosty nights, rainy days, and muddy roads, had rendered their appearance less clean and beautiful than it otherwise would have been, yet we venture the opinion that many of them would not suffer in comparison with the best animals in some of the older counties. There were several calves of improved breeds which excited much attention, some five or six yoke of working oxen were presented, of the most stately and beautiful appearance, and were much admired.

The number of horses, &c., on the ground was very satisfactory, and better pairs of matched working horses, such as the farmer wants, can hardly be found.

Of the swine exhibited, some were specimens of very good Berkshires, Chinas, &c., but the show was not very numerous, nor as good as may be expected in future years. Enough was to be seen however, to

convince the observer that our pork makers were determined to improve their breeds of porkers.

The different varieties of sheep, were several of them represented. The Merino, Saxons, Bakewell and South Down were by no means indifferent specimens of these varieties, some of which attracted much notice. One buck introduced by Mr. H. C. Soumeier, was very much admired on account of its fineness of the wool and size of the carcass. A full blood South Down Buck exhibited by Mr. J. W. Beck, of Canbria, presented a good combination of the most desirable qualities for the same grade, in superior quality, and a fair quantity of wool, with a size of carcass and a robustness of form showing a strong and vigorous constitution. There were other pens perhaps equally deserving, which I did not particularly notice.

The show of vegetable products, such as beets, carrots, pumpkins, squashes, &c., were such as to prove that the soil and cultivation of Niagara, (some per cent,) are not surpassed anywhere. A sugar beet exhibited by Mr. E. W. Smith, raised on as hard an clay soil as can be found, weighed 224 pounds, showing what may be done by cultivation. Several specimens of cauliflower, also raised on the same ground, were most splendid. Whitehead and Canbria furnished pumpkins weighing 49 pounds and upward. Squashes large enough to fill a half bushel measure were exhibited by Mr. Atwater, of Lockport.

The specimens of wheat and corn, oats and potatoes, were admirable. As fine samples of wheat can be found in the world, were exhibited; corn at oats at the rate of 90 bushels per acre, and potatoes the rate of 400 bushels per acre, and that too, without any reference to an agricultural exhibition, give some evidence at least, that our border county contains the soil, and the cultivators thereof, which will not suffer in comparison with many others which are celebrated. Notwithstanding great credit is due to our yeomanry, to our breeders of cattle, horses, sheep and swine, yet a word of praise not a whit less, due to the "ladies of the farm house," many of who graced our numerous assemblages, not only with the presence but with the work of their hands. The exhibition of carpets, flannels, woolen yarn, stocking socks, &c., &c., were all respectable, and some of very much admired. But in the article of butter, there were many samples of superior excellence. One of the viewing committee remarked to me, that he had served in the same capacity 14 years, in a western county, and that he never had seen so many perfect samples of butter, a fact reflecting much credit upon this branch of household manufactures.

When we consider that this was the first effort the kind ever attempted by us; that our society was organized all near the last of June,—that the 1st of premiums was not made known till the middle July, so that no stock, or vegetable could have been raised, or cultivated in reference to such premiums, what may we not expect when our society shall have attained years of maturity and experience.

Yours, &c.,

NIAGARA.

Lockport, October 25, 1841.

The election of officers for the ensuing year, which took place on the day of the Fair, resulted as follows:

WM. A. TRENSEND, President.

DAVID S. HURD, Vice President.

JOHN GOULD, Jr., V. President.

WM. PARSONS, Secretary.

WM. O. BROWN, Treasurer.

Executive Committee.

CAMBRIDGE—Thomas Comstock, D. W. Cropley, H. McNeil.

HARTLAND—C. H. Skeels, Abner Kuidge, Ha. Harrington.

LOCKPORT—Joel McCollum, Jacob Gaunt, Riv. Stevens.

LEWISTON—Asahel Lyon, Rufus Spaulding, Pheto.

NIAGARA—Parkhurst Whitney, C. H. Wynn, Elphinst Gilet.

NEWFANE—James W. Smer, Peter McCollum, W. Merritt.

PORTER—J. C. S. Ransom, J. Clapsdille, Jac. Mort.

PENDLETON—John Baker, George Hawley, Am. Parsons.

ROYALTON—Win. Freeman, Erasmus Hurd, V. Carpenter.

SOMERSET—M. S. Douglass, Peter Hleas, J. V. Bowers.

WILSON—Daniel Dwight, Daniel Holmes, Mor. Johnson.

WATERBURY—N. M. Ward, J. Greeney, H. Mil.

The Farmer.

If I was asked who belonged to the privileged order of our land, I should reply, the farmer, for no other reason than that he is rarely ever the victim of those fluctuations of trade and the currency—and that he is entirely relieved in the sale of his products from the evils of that credit system to which almost every other class of the community is subjected.

Whether the price of the necessities of life be high or low, it is all the same to the farmer so far as he produces them for his own consumption. His surplus, unlike the wares of the tradesman, or the products of the manufacturer and the mechanic, will always command cash, and on that account it is at all times free from those assessments which the credit system never fails to impose on the capital and products of the other classes of community; in fact it is always the farmer's own fault, and it can never be said that it was an evil incidental to his profession, if he is ever found linked with bankruptcy, or his substance diminished by bad debts.

Look at the poor unfortunate miller and the produce-buyer, growing up under the hot-bed influence of Banks, which gives an additional stimulus to their already too active gambling spirit. They are the farmer's victims.

Look at the clergyman, faithful and gifted as he may be in teaching those lovely lessons which make man godlike; yet is he hardly sure from one year to another of a place whereon to lay his head.

Look at the lawyer, now staying, unless he can get practice in that juries court, whose title burlesques the name of equity.

The merchant and the trader encumbered and paralyzed by competition, bad debts, embarrassment, bankruptcy. A victim of the credit system and bankulations.

The mechanic, felony eating out his substance or flagrating his fair fame, in the shape of a States Prison brother;—often reduced to the hard necessity of making his employer rich before he can get his pay; in a career is too often one of labor and embarrassment. But the farmer with the staff of life in his barns, sheep on his hills, and pigs in his pen, laughs to scorn the petulant ills of life; 'tis true, he has his cares, but without them he would be much to be pitied. If every thing was done to his liking without his own supervision, the devil or some demon passion would become his master.

"Making his abundance, the means of want."

The industrious, provident farmer has the earth for his chemical laboratory, which, in common with his glowing vegetable surface teaches him many lessons. Flora's his handmaiden, and Ceres and Pomona shed their bounties upon him, making him nature's nobleman.

S. W.

Items.

Condensed from Exchange Papers, &c.

GREAT HEIFER.—A heifer, raised by Col. Paxton, of Colombian county, Pa., was recently exhibited at Philadelphia. She weighed three thousand pounds, is half blood Durham, and was sold to her present owner for one thousand dollars. She is five years old. This shows the great advantages which farmers would derive from crossing their native cattle with good full blood Durhams.

INDIA COTTON.—A lot of 100 bales of cotton was sold in the summer in London at 8½d. per lb., being the first shipped from Madras, from the new English plantation.

CARRIAGE SPRINGS MADE OF AIR.—Allen Putnam, of the New England Farmer, says that H. L. Ellsworth, (who is at the head of the patent office,) informs him that he lately signed a patent for a man to construct springs for rail cars so that the passenger

may read and write without any inconvenience; and that he rode in a car, constructed with such springs, containing 80 passengers, which fully answered the expectations and promises of the patentee. It appears that the spring is made by using upright 12 inch cylinders, containing air condensed to one-thirteenth of its usual bulk, on which a piston rests; but how the air is kept completely confined by this piston, while the latter plays freely, we cannot fully understand, as it is unexplained.

CORN OIL.—In Indiana, where corn is worth only 10 cents a bushel, lamp-oil is made from it, by grinding the corn, and fermenting it with malt; the oil rises, and is skimmed from the surface, and the meal fed to hogs.

TREES.—In Japan, there is a law, that no one can cut down a tree, without permission of the magistrate of the place and even when he obtains permission, he must immediately replace it by another.

CHEAP ROOFS.—A correspondent of the Farmer's Cabinet, says, that if rafters, are covered with kiln-dried half-inch boards, closely fitted at the edges, and these with sheathing paper, (such as is used under the copper of ships,) with a coating of tar added, an excellent roof is formed that will last many years. That the following composition was used in this way for a roof, twenty years ago, which is now as good as when laid: Eight gallons tar, two gallons Roman cement (water lime), five lbs. resin (rosin we presume), and three lbs. tallow; boiled and very thoroughly stirred, laid on the roof very evenly with a brush while hot. Sprinkle this while hot with sharp sifted sand, when cold apply another coat of tar, and of sand; and one coat of tar in six years.

An incombustible wash for the above is made by mixing six quarts of dry, water, slacked, sifted lime, with one quart of fine salt, and adding two gallons water, boiling and skimming it. Add to five gallons of this, one pound alum, half a pound of copraes, and slowly half a pound of potash, and four quarts fine ship sand. It may now be colored as desired, and applied with a brush. It is said to be as durable as stone, will stop leaks, exclude moss, and is excellent on brick work. Try it.

BUDGING ROSES.—Dr. Van Monro buds roses in June, so that they grow, and frequently blossom the same year. He prepares the young and unripe wood by separating the leaves, leaving only the foot stalks; two weeks after the buds are swollen and fit for insertion; at the time the bud is put in, the stock is cut off six inches above it. They are bound with bass matting, previously drawn through a solution of alum and white soap, and dried, which completely excludes water.

TO REMOVE OLD PUTTY.—In taking out broken window glass, nitric or muriatic acid will soften the putty at once.

TRANSPLANTING EVERGREENS.—Pines and spruces are judiciously considered a great ornament in door yard scenery, and few ever succeed in transplanting them successfully. The following mode, copied from Downing's late admirable work on Landscape Gardening, though not altogether new, is excellent, and we hope many will be induced to practice it at this season of comparative leisure. "The trees to be removed are selected, the situations chosen, and the holes dug, while the ground is yet open in autumn. When the ground is somewhat frozen, the operator proceeds to dig a trench around the tree at some distance, gradually undermining it, and leaving all the principal mass of roots embodied in the ball of earth. The whole ball is then left to freeze pretty thoroughly, (generally till snow covers the ground,) when a large sled is brought as near as possible, the ball of earth containing the tree rolled down it, and the tree set in its new position."

to the hole previously prepared, where it is placed, in the proper position; and as soon as the weather becomes mild, the earth is properly filled in around the ball." When skilfully performed, says Downing, this is the most complete of all the modes of transplanting, and the trees scarcely show, on the return of growth, any effects from removal.

Germinating Seeds Under Colored Glass.

The following remarks by "Mr. Hunt, the Secretary of the Royal Polytechnic Society," in England, relate to a most curious discovery; and, one which may prove very useful to the cultivators of rare exotics. We hope some of our readers will be stimulated to repeat the experiments, and to send us the results.

"It is scarcely necessary to explain that every beam of light proceeding from its solar source, is a bundle of different colored rays, to the absorption or reflection of which we owe all that infinite diversity of color which is one of the greatest charms of creation. These rays have been long known to possess different functions.

"The light which permeates colored glass partakes to some considerable extent, of the character of the ray which corresponds with the glass in color; thus blue glass admits the blue or chemical rays, to the exclusion, or nearly so, of all the others; yellow glass admits only the permeation of the luminous rays, while red glass cuts off all but the heating rays, which pass it freely. This affords us a very easy method of growing plants under the influence of any particular light which may be desired.

"The fact to which I would particularly call attention is, that the yellow and red rays are destructive to germination, whereas under the influence of violet, indigo, or blue light, the process is quickened in a most extraordinary manner.

"The plants will grow most luxuriantly beneath glass of a blue character; but beneath the yellow and red glasses the natural process is entirely checked. Indeed, it will be found that at any period during the early life of a plant its growth may be checked by exposing it to the action of red or yellow light.

"It is with much satisfaction that I find the results to which I have arrived, corroborated by Dr. F. R. Hornor of Hull."

Blue glass for hot-beds could be very conveniently employed.

How to Have Good Peaches—Indian Corn.

Much has been said and written about preserving the life and fecundity of peach trees. From the great success attending the recent practice which has come under my observation, I am inclined to believe that keeping the ground under the trees clear from grass and weeds, and loose and mellow by continual working, with a judicious application of manure, will do more towards preserving the tree and improving the flavor of its fruit, than all the nostrums in the world.

It is said that the coffee tree can only be made profitably fruitful, by adopting the above plan. A coffee planter would as soon allow his yard and planting patches to overrun with weeds as his coffee grounds.

I am much gratified to see of late a more lively interest in the better cultivation of that King of the vegetable kingdom, Indian corn. If it is true, that stalks alone, can be more profitably cultivated for sugar than sugar beets, as affording more saccharine matter, and requiring less outlay of capital and expense in the manufacturing process, then truly a happy new era has arrived in the rural economy of the north and west, which will give wealth and independence to the great corn growing region of the great West.

The red blazed is the favorite variety of corn among the masterly corn growers of Oneida Co.—it has a small cob and large kernel. It is earlier than the Denton, and grows larger in Seneca than in Oneida.

9. W

fact and manure used upon it; the quantity of manure the present season; the quantity of seed used; the time and manner of sowing, cleaning and harvesting the crop; the amount of the crop determined by actual measurement; and the expense of cultivation. The land shall be measured by some sworn surveyor, and the claimant of the premium, with one other person shall certify to the above particulars.

Applicants for the premiums on butter, cheese and farm crops, must make known their determination to *LESLIE TUCKER*, Albany, (if by letter, post paid,) on or before the first of January next, and the parcels deposited in such place in Albany as the Ex. Committee may hereafter direct, on Tuesday morning the 18th of January, before ten o'clock, at which time the committee will proceed to examine the lot offered for premiums.

Hints for the Month.

Winter is now upon us—and the farmer must be diligent to secure what he has gained by the labor of summer. Flocks and herds need close attention, or they will soon lose much that has been gained by half year's care.

Animals thrive rapidly in warm weather—this thriving may be continued through winter, by creating artificially the advantages of summer; for instance,

The green and succulent food of summer is imitated by feeding roots copiously;

The comfort of summer may in some degree be conferred by having good stables and other shelters;

And other things may add materially to these, as the frequent salting of food; the free use of good water; and constant supply of pure fresh water:—

To feed an animal on dry food exclusively, would be like feeding a man on dry Indian meal, which would be rather hard;

To deprive it of shelter, would be like making a man sleep in the snow drift, which would be rather odd;

And to deprive a man of drink and condiment, he would think we rather short allowance. All would have a tendency to thin off his flesh; and what would deuce the flesh of a man, would tend to reduce the flesh of an animal. A want of comfort is a waste of flesh.

Horses that have run to grass all the past season, could not be kept on dry hay and grain; the danger of disease, so common at this season, would be greatly lessened, if they had a liberal supply of roots. They can learn to eat all kinds.

Be very careful not to waste fodder—have good racks and feeding troughs.

Chop up cornstalks finely for cattle; the body of the stalks, usually wasted, is the richest part. If Win. Cobb of Delaware, can make 1,000 lbs of sugar on an acre of cornstalks, after the leaves are stripped off, such rich and sugary fodder should not be thrown away. Salt it and meal it, and they will soon eat it.

Straw, or coarse hay, sprinkled with brine, is readied by cattle, and the salt does them good. Thrash your grain soon, before the rats eat it.

Repair broken tools, and procure new ones, of the very best construction only.

Read the New Genesee Farmer for the past and present year, make a memorandum of every thing worth practicing, arrange these memoranda for every next season, and put them into actual operation each proper season arrives. Pursuing this course, in a few years, any man of decent common sense a first rate practical farmer. Try, if you have a doubt,—and if you have not, try.

Do not forget to send your half-a-dollar for the next volume of the Farmer, and ask your neighbor to do likewise.

Dry Feet.

Observing in the last New Genesee Farmer a prescription for "New Boots," and believing the protec-

tion of the feet from damp and wet, a matter of much importance, as well conducive to health as to comfort, I take the liberty of giving a better composition. It is in fact the same receipt, (which I found a year ago in another agricultural paper,) but so much improved upon that I think it worthy of record.

The tar on (or rather in) the soles, I have used for a great number of years, and have found that it not only made my boots water proof, but nearly proof against wearing out. The receipt is as follows, and is to be used for the "uppers" only.

Nuts-foot oil,	1 pint.
Beeswax,	1 ounce.
Spirits Turpentine,	1 do.
Tar,	1 do.
Burgundy Pitch,	1 do.

To be slowly melted together and well incorporated by stirring, taking care not to set the mass on fire, as the articles are all highly inflammable.

The boots being damp, the composition is to be spread on with a small brush, taking care to cover the seams well, and then allowed to dry. The application to be renewed until the leather is saturated.

The above is for the "upper leathers"—for the soles, car alone is the best application, to be put on while hot, the boots also having been by the fire, so that the soles are quite warm. If there is no grease or other foreign matter on the soles, three or four, and sometimes more, coats will sink into the leather. It must also be used until the soles are completely saturated.

Boots whether "new" or old, (provided they are sound) will, by the above, be rendered entirely water proof, and the leather not only retain its elasticity, but become soft and pliable, and less liable to crack, as well as much more durable.

Nor will there be the objection that there is to boots rendered water proof by linings of gum elastic; for these being also air tight, the feet are kept, when exercised, in a constant state of perspiration, which is very uncomfortable as well as prejudicial to health.

The trouble of preparing boots after the above directions is very trifling, and any one once having tried it, and experienced the comfort of being all day in the snow and slush without having wet feet, will never fail to continue the use of it.

Cazenovia, Nov. 20, 1841.

[We borrow the following dialogue from the New England Farmer, but hope our readers will consider the sentiments our own, and addressed to them individually.]

Lend us a Hand.

Farmer A. Yes, Mr. Editor—I'm not very busy now—I'll give you a lift. What do you want done.

Editor. I want you, now that you have got your fall work well done up, and can spare a little time, to write out an account of your process in reclaiming that meadow of yours, where you now cut 2½ tons of English hay per acre.

Farmer A. I thought you asked for a hand—that I could bave lent; but you seem to be calling for head work, and that's quite another affair; I don't know about that.

Editor. I want the hand at the pen.

Farmer A. At the pen that's where it don't work very well: it's too stiff for pen work—let it go to the shovel, or spade, or hoe, and it feels at home, and will work well, and the head will work with it down in the ditch; but when you come to put the huge paw upon white paper, the head won't work right, and the fingers don't move right. I don't know, Mr. Editor, about my helping you.

Editor. Well, suppose none of you practical men write, how shall I make up such a paper as you want? The facts which common farmers give to one another through the papers, are the most instructive and useful part of our weekly sheet; and if you want tell what you have done, and farmer B. won't tell what he has done—if all the others all the way down the alphabet won't tell—why then the editor can't furnish all that you want—he can't furnish what you want

most. He can theorize and give advice, and extract from other publications; but he can't get hold of the important facts, unless you—yes, you, and others like you, will "lend a hand" and a head too. Come, now, farmer A., give us a few lines, and set a good example.

Farmer A. Fact, Mr. Editor, what you say takes a level of the starch out of my fingers. I never saw the motto right in that light afore. I want to know how neighbor D. and his hundred bushels of corn to the acre; and how Mr. W. raised his 'leven hundred of taters. I'd like to have 'em write all about it; what kind of land it was—how once they plow'd it; dung'd it, and work'd on it. Yes, I'd satnly like to know all about it. But as to my meddling, Mr. Editor, why it's done pretty well, as to that. I do get a good crop of English hay where I did it; it's got nothing to speak on, and that poor stuff. I'd like to know how other folks work it, and if you really think, Mr. Editor, that my writing would set them at it—why then I'll try.

Editor. That's right, sir—that's right. Now, farmers, send in your statements, without further invitation.

Make Home Happy.

It is a duty devolving upon every member of a family to endeavor to make all belonging to it happy.—This may, with a very little pleasant exertion, be done. Let every one contribute something towards improving the grounds belonging to their house. If the house is old and uncomfortable let each exert himself, to render it better and more pleasant. If it is good and pleasant, let each strive still further to adorn it.—Let flowering shrubs and trees be planted, and vines and woodvines be trailed around the windows and doors, and interesting volums to the family library; let articles of furniture to replace those which are fast wearing out; wait upon and anticipate each other's wants and ever have a pleasant smile for all and each.

Make home happy! Parents ought to teach this lesson in the nursery, and by the fire side; give it the weight of their precept and example. If they would our world be a happy and more virtuous country.—Drunkennes, profanity, and other disgusting vices, would die away; they could not live in the influence of a lovely and refined home.

Does any one think, "I am poor and have to work hard to get enough to sustain life and cannot find time to spend in making our old home more attractive." Think again! Is there not some time every day which you spend in idleness, or smoking, or more uselessness, which might be spent about your homes?—"Flowers are God's smiles," and Wilberforce, and they are as beautiful beside the cottage as the palace, and may be enjoyed by the inhabitants of the one as well as the other. There are but few homes in our country which might not be made more beautiful and attractive, not to strangers only, but to their inmates.—Let every one study then, and work, to make whatever place they may be in, so attractive that the hearts of the absent ones may go back to it as the Dove did to the ark of Noah.—*American Farmer.*

It is not essential to the happy home that there should be the luxury of the carpeted floor, the richly cushioned sofa, the soft shade of the astral lamp, these elegancies, gold the appointments but they reach not the heart. It is cleanliness, order, and a cheerful heart which makes home that sweet paradise so often found to be. There is joy, as well, as heartily, by the cottage fireside as in the most splendid saloons of wealth and refinement. What a lovely picture has Burns given us of the return of the cottager to his home, after the labors of the day.

At length his lonely cot appears in view,
Beneath the shelter of an aged tree,
The expectant wife, tottering stagger through,
To meet their dad, with fluttering noise and glee.
He then, beneath stone, his thrifful wife's smile,
The hissing infant prattling on his knee,
Does all his poor carking cares beguile,
And makes him quite forget his labor and his toil.

The luxuries and elegancies of life are not to be despised. They are to be received with gratitude to Him who has provided them for our enjoyment. But their possession does not ensure happiness. The sources of true joys are not so shallow. Some persons, like some reptiles, have the faculty of extracting poison from every thing that is beautiful and sweet; others, like the bee, will gather honey from sources in which we should think no sweet could be found. The cheerful heart, like the kaleidoscope, causes most discordant materials to arrange themselves into harmony and beauty.

Talk little and say much.

On the Different Breeds of Cattle.
To the Editors of the New Genesee Farmer.

GENE.—At the present time there appears to be a great diversity of opinions in regard to the different kinds or breeds of cattle which are best calculated for the farmers of our Northern latitudes. What conclusion can a disinterested person arrive at, if he is governed by the different articles which are penned on this subject? Were we governed by all that contend for the increased value of the different varieties of meat stock, we might arrive at a safe determination upon this point, yet but few of our farmers are able, and if so, willing to go into the rearing of those breeds which stand in higher order than our native stock, as all enterprising men are willing to be governed by the experience of those persons or nations that have excelled in that kind of business which is necessary in a course of farming operations. If we place due credit to all that have written on this subject, and no doubt from a thorough conviction of the truth of their observations in this branch of business, we shall find that all, or nearly so, vary in their observations according as they are interested, consequently we farmers must be governed by those who have two or more of the different kinds, &c.: Devons, Darhams, and Herefords, which seem to stand pre eminent amongst all distinguished breeders, both in England and the United States. Yet, in England, we find a variety of conflicting opinions in regard to the above breeds as in the States, for instance—in Cultivator, Vol. 5th, No. 1, page 17, we find a Mr. Price in England, challenging the Kingdom to produce as fine a stock of cattle as those reared by him, which were pure Herefords. But on reading further we find a Mr. Bates who was ready to meet him in his challenge by producing a stock of pure Darhams; but sickness of the former gentleman was the cause of the failure in the testing between the exceedingly fine qualities of those two stocks, which would have been a great point decided if disinterestedly upon their true merits. Mr. Bates remarks that he thinks the very best Short Horns, which are only a few, are capable of improving all other stocks in the Kingdom, yet he says the common Darhams are inferior to the Devons, Herefords and others, which is candid in him. It seems also, from the statement of Mr. Howard of Gainsville, Ohio, that in the year 1825, there were sent from England, as a present to the Massachusetts Agricultural Society a true Hereford Cow and Bull, from Sir Isaac Coffin, of the Royal Navy, which proved a great acquisition to the stock of that country, and were highly appreciated by the teamsters from their fine horns, stately gait, powerful draught and beautiful mahogany color, &c.

In the same article which will be found in Cul. Vol. 8, No. 1, page 19, he says—"I will here remark that I knew many and owned several of the progeny of the improved Short Horn Bull Admiral (which animal was also sent as a present by the same Mr. Coffin to the Massachusetts Agricultural Society) and I have no hesitation in saying that for the ordinary uses to which cattle are applied in the Northern section of our country I considered the stock of the Hereford Bull allied to decidedly preferable." Next we hear from a very intelligent rearer of stock, Mr. Hopburn in Cul. Vol. 8, No. 2, page 35, in an article which says, "that an argument to prove that the Herefords are an aboriginal race is the largeness of the head and thickness of the neck when compared with the Devon cattle."—Further he states, "were it not for the white face, thick neck, and large head, it would not be easy at all times to distinguish a light Hereford from a heavy Devon," &c. &c. His ideas are quoted from Youatt. I would here remark, that by some the Herefords are considered a distinct

species of cattle, by others a cross of the Devon, with some larger breed. From the best sources of information, I should think that they were most certainly a cross of the Devons with most probably the Darhams. In support of this I would also refer the reader to an article written by Judge Buell, in Cul. Vol. 5, No. 1, page 8, headed "Select Breeds of Cattle." He also, in the same article quotes from a British author in high terms of a cross between the Holderness and Durham for the dairy, and ends in these words: "The Devons were introduced into Berkshire county some dozen years ago, by Col. Dwight, and at the last fair in that county we thought the working cattle surpassed any we had before seen, and we attribute their excellence in a great measure to the Devon blood which we saw strongly developed in some of the finest individuals. We unhesitatingly recommend a cross of the Devons upon our native cattle, as a certain means of improving both their working and fattening properties." In the foregoing extracts which are only a few that might be cited from good authority, what course is it proper to pursue in getting certain and correct information, so that in improving our stock we shall not be disappointed but what we have the best animals for the country and latitude in which we live? I am aware that it is impossible to have a breed of cows which will keep fat and give great quantities of milk.

I would upon the whole, from the conflicting opinions and views of those who are interested in rearing and selling their stock, that farmers who are wishing to improve their stock, (and I doubt not but what all are), that a course of inquiry be instituted from those gentlemen who have Bulls and stock to sell—setting forth by their own statements, and corroborated by the certificates of their neighbors, what has been the course pursued in feeding their improved stock, in comparison with their other stock, and the result accordingly. For instance, if a cow gives 25 quarts of milk per day on the same feed of another cow which gives only 20 quarts, then state the different results of butter made from the milk of each which may easily be done by the Lactometer which is a tube of glass graduated, which readily shows the percentage—as I presume all are aware that it is not the best cow in all cases which gives the most milk, as experiments go to show that in some cases the milk varies in goodness some 50 per cent, according to quality. In short, we want to arrive at the fact which breed of cattle will produce the most net profit from the same feed—requiring each breed to stand the severity of the climate alike. In conclusion I would ask of Mr. Saxford which he considers the best breed of cattle, the Durham or the Devon? as I see in the report of a visit of Rawson Harmon Jr., of Wheeland, in the August number of the New Genesee Farmer that he has both kinds of Bulls on his farm.—Also state which of these two breeds he considers best for the majority of farmers in Genesee county. State fully which will stand our cold winters best, feed us the *one* of the extensive wheat grower in the county.—Also which are the most profitable to raise for the eastern market, considering the keeping, &c. By answering these questions he will confer a favor on

Yours Truly,
Genesee Co., Nov. 11. A. SUBSCRIBER.

On the Importance and Utility of the Dissemination of Knowledge Among Farmers.

MISSES. EDITORS.—I owe an apology to you, if not to your readers, for the delay in further considering the subject proposed in my first article, which perhaps was hardly worth the space it occupied in your paper, and still less the attention of your numerous readers, though honored by an insertion.

I am aware that, in treating upon subjects about which there has been much said and written, there is

great danger of falling into old and beaten tracks, where nothing new can be introduced to attract the attention of the reader. If in the further remarks which I shall submit on the subject already introduced, I may be so fortunate as to present some considerations that will not have a "hackneyed" appearance, I shall consider that neither my time, nor your space, will be unprofitably occupied.

I propose to speak mainly of the importance of the dissemination of knowledge among farmers, as the greatest if not the only means of establishing a proper system of human economy in society, and as the surest method of procuring the greatest amount of social happiness. There would be but little to compensate for the toil and exercise of the mind and body in procuring something beyond a competency of food and maintenance, if the demands of nature did not also require every man to provide for certain social duties and advantages. The elements which compose the best regulated and best organized society, experience teaches us, may be comprehended under the head of virtue and wisdom. This idea may be at variance with the prevailing notions of the day, still it is acknowledged by the candid and reflecting portions of community over whom custom as yet, has not had sufficient influence to make them mistake the true test of character. It is a popular, and may be said to be a prevailing delusion, to judge of the shadow instead of the substance of what in fact constitutes a character for worthy association. The modern notion of refinement, has set up an arbitrary rule, by which external appearance and outward show, accompanied by certain set forms of ceremony and etiquette, are made requisite qualifications for such as wish to mingle in what is called polished society. Thus it frequently happens, that the most worthy, are overlooked and neglected, from the fact, that the fashion of their dress, and their way of thinking which constitutes an exquisite bow,—the are called "backward fellows" because they have not learned to play the hypocrite in those absurd notions with which community has already been too much loaded. The dignity which always graces a man, refined talents, a bright intellect and a well stored mind, all tending especially to qualify for social duties, are now looked upon by the devotees of fashion as secondary considerations, and by too many will pretend to take the lead in giving a direction to public opinion, as of little consequence. And it is to be regretted, that wealth, power and education are not the evil instruments to produce the advancement such a state of things, when, on the contrary, they might be the means, and God who gives, grants them; no other purpose, than as elements ministering in the establishment of sound principles, which insure freedom of action, and the enjoyment of both body and soul.

The occupation of a farmer is looked upon, by the class alluded to, as disqualifying him for the high rank they have assumed for themselves, while the discernment and common sense of the man who tills the soil, forbids that he should desire such associations, envy their station, in preference to the peace and tranquility of his own. Properly considered, there is no situation in life, in which a man may be placed affording him greater advantages, than that of a farmer. This proposition needs only to be reflected upon, and to be made at once convinced that it is true. While in all the other occupations in which men are engaged there be found so much time for reflection, where the mind is left free to form sound views without being contaminated by the evil associations of such as are not permitted to enjoy the blessings so favorable a retirement. It is a common error among farmers, that the business in which they are engaged, shuts them out from the enjoyment of advan-

es so abundantly secured to other men. What are commonly called great advantages are by no means secured alone to any one class of society; indeed, there but little worth seeking for, but what may be obtained by all who are willing to make the effort. The fact that a polished education is an indispensable requisite for the acquirement of knowledge, and that education will only enable one to possess intelligence, is not only erroneous, but a mischievous conception of the mind. For such as would arrogate to themselves the right of monopoly over the abundant truths which are pouring into the mind of every one, the lights of knowledge and intelligence, is not surprising to hear them advance such an idea. Upon the importance of education we cannot however place too high an estimate, for the benefits which it has and ultimately must bestow upon mankind. But it is only when education is used as a means of enlarging the capacity of the mind and preparing an individual to fill the useful station in society, that the greatest good will result from it. And on the contrary, if used as an instrument of producing those sickly plants, too frequently sent forth from our schools of learning to play the fop or the pino, it overloads society with a set of useless beings, that are a burthen upon it. From the knowledge of educated men Agriculture has not failed to receive important aids, but not, when compared to other things of less importance, its due proportion of benefits. When considered a science, as it truly is, it is easy to conceive that the study of it might profitably occupy the most polished mind, and perhaps there is not a science from which educated men, who strive to apply their knowledge to useful purposes, have derived greater pleasure, than from the study of the principles which cause the earth to produce all the wealth of which individuals or even nations can boast. I venture to predict, that no one to whom has applied his talent, education, or experience, the examination of the most simple principles of husbandry, but what has found an ample scope for the profitable employment of either. But while such as are engaged in what are termed "professional pursuits," are obliged to become acquainted with the ancient languages, in order to be familiar with certain obscure terms and phrases, the former has no occasion to recollect any but the most simple terms to gain all the knowledge his most ardent desires may demand. The school of practice he has daily opportunity for gaining knowledge, while at the same time, experience and practical observation, will enable him to demonstrate every principle connected with the business of his life. Comparatively but few engaged in it, consider how important is the calling of a farmer, and many have settled down under the conviction that chance or necessity has compelled them to a station, if an opportunity had offered, their choice could not have dictated. From this, perhaps, more than any other cause, the but too prevalent idea has originated, that this class of our fellow citizens are set on as only worthy of the associations of the "second class." What error has failed to do in filling the minds of many with false notions, prejudice has failed to accomplish the whole work: and therefore it is, that a more general dissemination of knowledge may be considered necessary.

In my next it will be my purpose not to deal so much as heretofore in general remarks, but shall endeavor to confine myself to a more particular application of the subject. Yours, &c.,
C. P. T.
Batavia, Oct. 20th, 1831.

For the New Genesee Farmer

Annual Exhibition

of the Massachusetts Horticultural Society—Horticulture in Monroe County, &c. &c.

It will doubtless be gratifying to the friends of Horticulture throughout the country, to hear something of

the late Annual Exhibition of the Massachusetts Horticultural Society, held on 23d 24th and 25th of Sept.

From the report published in the October number of the Magazine of Horticulture, it appears that the variety of Fruits was greater than any ever before exhibited in the United States. Mr. Manning, of Salem, the greatest promologist in America, sent one hundred and thirty kinds of Pears; Mr. Wilder, the President of the Society, fifty; Mr. Cushing, forty, and many other gentlemen, thirty, twenty and ten each. A magnificent pyramid of Grapes, comprising twelve varieties on a line of Pines, Nectarines and Plums was presented by Mr. Haggatson Gaudinier to J. P. Cushing, Esq. The exhibition of vegetables was also unusually good. The Dublin show far surpassed any previous exhibition of this splendid flower by the Society, and the number of Pot plants, Cut flowers, Boquets, &c., was very great.

At the close of the exhibition the members celebrated the 13th anniversary by a dinner, after which several excellent addresses were delivered and appropriate toasts and sentiments were given,—of the latter we have selected the following, as our limited space will not admit of publishing all:—

Agriculture and Horticulture—The first nation's greatest wealth, the next its greatest luxury.

The Cultivation of the Field—It was the first act of civilization, and is the basis of all other branches of industry and is the chief source of the prosperity and the wealth of nations.

The Primæval Employment of Man—To dress the garden and keep it.

Horticultural Societies—"Fiscal corporations" whose capital stock is a well cultivated Bank of Soil, whose Directors are producers, whose depositors get cent per cent for their investments, whose exchanges are never below par, and which "operate *per se* over the Union."

The Massachusetts Horticultural Society—Its birth has opened a new era in the horticulture of New England.

The Rose—While we acknowledge her as Queen at the court of Flora, we are happy to recognize among our guests the distinguished representative* of that Queen, whose Kingdom have adopted in the Rose their Floral emblem.

Horticulture—The art which strews our paths with Roses—lands our tables with luxuries, and crowns our labors with the rich fruits of contentment and happiness.

Women—A seedling sprung from Adam's side,

A most essential share,

Because of Paradise the pride,

And bore a world of fruit."

We cannot but do justice in this brief notice to the report, which occupies nine pages of the Magazine, and much remains yet to be published. This Society is one of the most useful and flourishing of the kind, in the country. But 13 years ago since it was organized; their meetings were at first held in a small room; and by steady and persevering efforts worthy of all praise, they have gradually advanced so that now they occupy a spacious hall in Tremont Row, Boston. It would be impossible to estimate the advantage which have resulted from their labors, not only to New England, but to the country at large. Mr. Walker, a prominent member of the Society, in speaking of this, remarked, "who can recount its acts and the benefits thereof to the community and after generations? Had I the eloquence of a Cicero, it might be exhausted on this subject."

We would strongly recommend this subject to the attention of Cultivators in our own favored district. In view of such results the friends of Horticulture should want no other inducement to associate themselves together for the purpose of promoting Horticultural improvements. Every instance where proper attention is bestowed to this branch of industry, proves most satisfactorily that we possess the means, if we only avail ourselves of them, to excel both in quantity and quality of our Horticultural productions. At the

* Mr. Gatten, the British Consul at my eldest.

and Agricultural Fair for this county the exhibition of garden productions was exceedingly limited, only about half a dozen exhibitions of fruit—two or three of flowers, and five or six of the more common sorts of vegetables. This, for the Horticultural department of the Fair for the whole county of Monroe, will be admitted by all to be far from what it ought to be, and argues forcibly the necessity of making some advancement that will excite more general interest on a subject of such vast importance to the public. P.

From the Illinois Cultivator.

The Short Horns as Milkers.

Mrs. GAYTON & TRICKER.—In the June No. of the Cultivator there appeared an article, signed Lewis F. Allen, in which the opinion was advanced, that the improved Short Horns were the stock best adapted for New England dairies.

The ability with which this article is written, and the source from which it comes, ensures it great weight with your readers. But as this opinion is contrary to that of most agriculturists in this neighborhood, (the vicinity of Boston) I have been in hopes of seeing an answer to it in your paper by some one more familiar with this subject than myself.

That this stock is the best suited to the rich pastures and fertile lands of New York and the Western states appears to be generally admitted. Are they equally well suited to the thin soils and scanty pastures of New-England?

In the act of saying too much for his favorites, Mr. A. has given them less praise in some respects than we should readily concede to them. He compares them with our average native cows; we are in the habit of comparing them with our good dairy cows. The quantity of milk given by the Short Horns as compared with our average native cows is greater than Mr. Allen asserts. The quality of the milk is considered by us generally as inferior to that of the common cows of the country. Much of it would not, I think, sell readily for milk. This is contrary to Mr. A's experience with his Short Horns; and there are certainly among the grade cows many exceptions to a here.

Writers are too apt to forget that the most important question, and what we really want to know is, what stock or stocks will give us the best and cheapest milk, butter, cheese, and beef; and it costs stock will give us the most per centum. If it costs three times as much to raise and to keep an improved Short Horn in our climate and on our soil as one of the native breed, although it gives twice the butter and cheese and twice the beef, it may be a poor stock for us.

No one here I think would be inclined to accept the wage offered by Mr. Allen at the end of his communication; for we do not content that ten or twenty cows, which should be a fair average of the native breed of New-England, would give as much milk, butter and cheese as ten or twenty cows of a breed of nearly twice their size when both lots had as much nutritive food as they could eat. That our cows seldom have all the ear food.

Mr. A. refers to British publications to prove the superiority of the Short Horns. Following his example, I will quote the British Husbandry and Low, as the best British authorities I know of on the subject. In British Husbandry, ch. 38, on milk cows, it is said, "the breed most esteemed in the London cow keepers who sell the milk without making butter or cheese, is of the old Yorkshire stock, or a cross between the Two-water and Holderness, as producing the greatest quantity; for they are in that case reared in the house, and of course provided with an abundance of cut grass brews' gramin, and succulent roots; but when grazed, they require very good pasture, and are not generally considered to produce milk of a rich quality. But the breed which of all others appears to be gaining ground throughout the United Kingdom for abundant produce upon ordinary pasture is the Ayrshire kyle."

David Low in his Elements of Practical Agriculture says, "By long attention to the elements that induce a disposition to yield milk, the breed of Ayrshire has become greatly more esteemed for the dairy than other animals much superior to them in size and feeding qualities."

I hope to see this subject more thoroughly discussed in your journal by Mr. Allen and others, who, like him, speak honestly what they sincerely believe.

A YOUNG FARMER.

Vicinity of Boston, Sept. 23, 1831.

ROCHESTER, DECEMBER, 1841.

Farewell—Till Next Year.

We feel somewhat reluctant to throw aside our present subscription book, containing as it does the names of nearly twenty thousand of our esteemed friends! But it can't be helped—and we hope to have the pleasure of recording them all again in a short time, with many more besides. We have got a larger and handsomer book for the next year, and all who wish the honor of having their names recorded in it, will send us FIFTY CENTS!

Uncurrent Money.

Bills of solvent banks in Ohio, Indiana, Kentucky, Pennsylvania, Canada, &c., will be received at par in payment for this paper, if sent free of postage and no commission deducted. Michigan and Illinois bills cannot be received at present. Bills of the Buffalo (Safety Fund) banks will be received from subscribers in Michigan and Illinois. (Till further notice.)

Travelling Agents.

We do not find it necessary to employ travelling Agents for this paper; but C. P. COLMAN, will act as such when travelling on his general business in the country. He will carry out Garden Seeds of his own raising and Corn Drosses and Brushes of his own manufacture.

The Editors.

Mr. Colman is expected at Rochester by the latter part of December—in time to superintend the next No. of the paper. The present editors will continue their assistance, and the character of the work will not be materially changed.

It may be well to remind some of our readers that the articles which are found in this volume, marked thus, * are written by David Thomas, of Aurora, Cayuga Co., and those marked thus, * are by his son John J. Thomas, of Macedon, Wayne Co.

Henry Colman.

Much has been said in praise of HENRY COLMAN, by agricultural papers of late, but as many of our readers probably do not see other papers of the kind, we deem it proper to give an extract or two by way of introducing him to their acquaintance. As we do this without his knowledge or consent, no one can accuse him of egotism on account of it.

The first is from the Farmers Monthly Visitor, edited by Ex-Governor Hill, of New Hampshire.

"The Massachusetts Agricultural Commissioner.—There is no man in America more ardent in the cause of Agricultural improvement than HENRY COLMAN, who is under the employment of the Legislature of Massachusetts, and who visits different points in that Commonwealth with the view to inspect the farmers and to present the results of his observations and labors to the public. For effecting his object, Mr. Colman travels in various directions among the yeomanry of the Commonwealth, with his horse and dog wagon and in almost as plain an attire as the workmen in his field. We have a few times seen Mr. Colman among the farmers at agricultural exhibitions and elsewhere; and the enthusiasm he exhibits on each agricultural topic cannot fail to infuse itself into the most insensible farmer and arouse all his energies. The conversational powers of Mr. Colman are equal to those of the best man we ever met; his language flows like a stream of pure water; and like many gushing rivulets that ooze from the hills and fertilize the land below, so do his writings throw translucent light upon the subject he describes.

The Commissioner will find but few equals in the art of describing the pleasures and the advantages of

a rural life, and of recasting that occupation on which all other occupations depend, from the neglect in which indolence or lack of enterprise attempts to obscure it."

The next is from the (Baltimore) American Farmer, the oldest agricultural paper in the Union, edited by John S. Skinner, a veteran writer in the cause.

"HENRY COLMAN.—We draw three lines under his name, as we believe it is the printer's sign for large capitals and because we would, in every way, do honor to an eminently useful man; and we know of no one whose labors of utility are more wide-spread, or likely to be more enduring than 'THE COMMISSIONER FOR THE AGRICULTURAL SURVEY OF MASSACHUSETTS.' There is originality, vigor of thought, and practical usefulness in his observations on the agricultural practices; and products, and capacities of his State, and his suggestions for the further development of its resources, that must strike every one, no whatever distance, who, by any chance, sees what he is doing."

The following is from the (Rochester) American Cultivator, edited by Gen. Wm. L. CHAPMAN, who is personally acquainted with Mr. COLMAN:

"I am happy to announce to the farmers of Western New York, that Mr. COLMAN has recently been able to secure the services of HENRY COLMAN, of Massachusetts, as a permanent Editor of the New Genesee Farmer. Mr. Colman was for many years an eloquent and popular preacher. He is a well-trained scholar, richly furnished with information in the various departments of literature and science—a man of warm and generous impulses, and an accomplished gentleman. His pen is sprightly, nervous and instructive. Some years since, he became a practical farmer in one of the most delightful spots in the beautiful valley of the winding Connecticut in the upper part of Massachusetts. From that time he has cultivated agriculture as a profession, with the loving enthusiasm of the most devoted artist. For a few years past he has been the Agricultural Commissioner of Massachusetts by the appointment of the Governor under an act of the Legislature; along with his keenness of observation, and his untiring zeal in the cause, he has enjoyed the amplest opportunities for acquiring and digesting a vast store of every-day available knowledge. It is hazardous nothing in saying, that it would be difficult, if not impossible, to find a man in the country whose qualifications are more largely adapted to give life and interest to an agricultural journal, than HENRY COLMAN."

He comes to Western New York, with the purpose of making it a man's residence. In comparison with New England, he will find a new country, whose resources as yet are but very partially developed, and but imperfectly comprehended by the people. He cannot fail to be delighted in anticipation of what industry and ingenious husbandry will one day make this garden of the State. It by his written essays and oral addresses he can succeed in imparting to a few leading minds, but a tide of his own enthusiasm in the pursuits of agriculture, a few years will produce a revolution in that department which will astonish us.

THE NEW GENESEE FARMER,
AND GARDENER'S JOURNAL.

VOLUME THREE—FOR 1842

THE Cheapest Agricultural Paper in the Union.—6 Large Pages Monthly, with engravings, only 50 Cents per year!!

HENRY COLMAN, EDITOR.

(Late Agricultural Commissioner of the State of Massachusetts, and Editor of the New Eng. Farmer.)

Grateful for the extensive patronage which the New Genesee Farmer has received in the last year, the proprietor now has the satisfaction of announcing that he has made such arrangements for the coming year as will tend to be highly gratifying to the readers of the paper, and secure for it a still more extensive circulation.

Desiring to make it the most useful and lively circulating agricultural paper in the Union, the proprietor has engaged the services of the able and practical agricultural writer and editor, HENRY COLMAN, well known as the late Agricultural Commissioner of the State of Massachusetts, and formerly editor of the New-England Farmer. Depending on the cooperation and support of the friends of agriculture in the Empire State and the Great West, Mr. Colman has consented to leave the field where he has labored long with so much honor and success, and taken up his abode at Rochester, where, through the medium of the Genesee Farmer, he expects to find a more extensive field of usefulness.

The former editors and contributors will continue their assistance, and care will be taken to make the paper interesting and useful, not only to farmers, but to all persons engaged in rural or domestic affairs. With such a combination of talent, the New Genesee Farmer cannot fail to obtain an immense circulation, thus giving new impulse to the cause of

agriculture—promote the best interests of community, and tend to increase the wealth and prosperity of the Nation. It is hoped, therefore, that every friend of agriculture—every well-wisher of his neighborhood and his country, will lend his aid, and not only subscribe himself, but induce his neighbors to subscribe also. The paper will be continued at its present low price, in order that its influence may be much widely extended. Its appearance will be considerably increased, and having now a Power Press exclusively for its work, greater promptness and regularity will be secured. Careful clerks are engaged to mail the papers, so that it is believed there will be little cause for complaint hereafter.

Post Masters and their Assistants, are authorized and respectfully solicited to act as Agents and remit subscription for the Farmer. The low price at which it is published will not allow of pecuniary compensation to Agents, but it is believed they will find a reward in the benefit which result from the circulation of such periodicals in their respective localities.

Persons ordering papers are requested to strictly observe the Terms, and be careful to give plainly the names of subscribers, their Post Office, County, and State.

No commission will be allowed, if no current money is sent. If current money is sent (such as New York or New England bills) commission will be allowed as follows:

Seven copies, for \$3.00 Payment always to 1
Twelve do. for 5.00 made in advance.
Twenty do. for 10.00

No commission will be allowed, if no current money is sent. Address, BATHAM & COLMAN, No. 12, December 1, 1841.

FARM AND SAW MILL FOR SALE.—25 Acres of cleared land and a half mile from the center of the city of Rochester, about 100 acres under good improvement, and the residue finely timbered with White Oak Chestnut, and other valuable trees. The Saw Mill on the farm has been recently put in complete repair and is rigged for either a single saw or a gang of six saws for sawing boat or ship plank. There is timber enough on the premises with the mill to furnish lumber to 1000 or 1200 farms. The buildings, besides the saw mill, are a comfortable dwelling house, and a large frame barn. About 35 acres are sowed with wheat this fall. For the purpose of making the men and teams engaged in farming in the summer, or the advantageously employed in lumbering during the winter, \$2000 will be required in advance, and the residue of the purchase money can remain on mortgage.

Apply to the subscriber at Rochester. GEO. W. PRATT, Oct. 21, 1841.

WESTERN FARMERS' and GARDENERS' Almanac for 1842.—By Thomas Allen, a practical man. Also "Key to the West," by the same author. Price 25 cts. each—\$2 per dozen, for sale at the Store and Bookstores in Rochester.—Nov. 1.

GARDEN SEEDS IN BOXES.—J. F. COLMAN has received a large quantity of Garden Seeds and a customer that he will at the usual time, be prepared to supply the with fresh assortments of garden seeds, of his own raising or selection, such as he is confident will give satisfaction. Rochester, Oct. 18, 1841.

HATCH'S PATENT SOWING MACHINE.

M. B. BATEHAM,

Intending to spend several months in Ohio, has obtained the Right of Hatch's Sowing Machine for that State; and he takes this method to inform his friends in that region, that he will soon exhibit among them one of the Machines in operation, a bare inspection of which will convince all that it is just what is needed by the Wheat Growers in the BANNER STATE. (For particular description, &c., see New Genesec Farmer, Vol. 2, p. 143—and Vol. 3, p. 112.)

Mr. B. will sell County Rights in Ohio, on very advantageous terms, to enterprising Mechanics.

Mr. Hatch will continue at Rochester, where he will be happy to receive any applications for Rights or single Machines. He deems it unnecessary to say any thing more of his Machine at present, than that the numerous and respectable farmers in Western New-York, who have used it, all agree in declaring that it is just what they wanted. He challenges the world to produce a better article for the purpose. Letters must be Post Paid.

Mr. Bateham will also act as the authorised Travelling Agent and Correspondent for the next Volume of this paper, which will be enlarged and improved. Terms, \$1.00 per year.

Bound volumes, 1, 2 and 3, are for sale by M. B. Bateham, and at the Rochester Seed Store.

THE NEW GENESEE FARMER.

AND GARDENER'S JOURNAL.

BATEHAM & COLMAN, } VOL. 3. ROCHESTER, JANUARY, 1842. NO. 1. } HENRY COLMAN, Editor.
Proprietors.

PUBLISHED MONTHLY.

TERMS.

FIFTY CENTS, per year, payable always in advance. Post Masters, Agents, and others, sending current money free of postage, will receive seven copies for \$5.—*Ten* copies for \$5.—*Twenty-five* copies for \$10. The postage of this paper is only one cent to any place within this state, and one and a half cents to any part of the United States. Address BATEHAM & COLMAN, Rochester, N. Y.

For Contents see last page.

Publishers Notice.

"We wish a happy New Year" to our numerous friends who have so promptly sent in their new subscriptions. Those who have not done so will not receive this number till that duty is attended to, and we insert this *Hibernian Notice* to inform them thereof!

Canada and Pennsylvania money, is at a discount of 7 to 10 per cent. here, and some of our agents complain because we refuse to allow them a commission on it. We now say that we will allow them one half of the usual rate of commission on such money, if sent free of postage.

Agents and officers of Agricultural Societies in Canada, are requested to remit payments to Messrs. Lamm, Farr, & Co., Toronto. Those who do so will be allowed the same rate for Canada money as last year.

A New-Year's Gift.

We print a few hundred extra copies of this number, and send them (with show bill) to Post Masters and others as a New-Year's Gift in return for the numerous favors they have granted us. We hope they will *please read and Circulate.*

Editorial Notice.

The necessity of Mr. Colman's attending to complete the publication of his Fourth Report on the Agriculture of Massachusetts, and a multiplicity of cares and labors incident to a removal from one home to another distant home, prevent his doing but very little for this number of the N. G. Farmer. He will endeavor to atone for present deficiencies hereafter. It is his expectation to take up his abode in Rochester about the 20th of January ensuing, if a kind Providence permits; and there at that time he requests his friends to address him.

EDITORIAL ADDRESS.

Few men who have had much experience of life venture upon any new enterprise without an oppressive and embarrassing feeling of the uncertainty of success. The young may be confident; the old know how many reasons there are for being wary and distrustful—of themselves as well as others. It is not always easy to satisfy one's self; it is often difficult to satisfy others; and what is best to be done and how it is best to do it, the most sanguine are often at a loss to determine. But it will not on that account do for us to hesitate to act; or to stand like the traveller on the rivers bank, who determined not to cross until the waters had all flown by. We must act; and in attempting to do the best we can, we may at least satisfy our own conscience, if we satisfy no one else.

I have now this struggle to go through with in undertaking the editorial department of the New Genesee Farmer; and I do not know how otherwise to determine it than as above. I promise my best services. I will do what I can to render this paper instructive and useful, agreeable and entertaining; serviceable to agricul-

tural improvement; conducive to the diffusion of wholesome knowledge; and the promotion of sound morals.

I enter upon the undertaking with an unfeigned diffidence, but at the same time with great pleasure. My mind has been many years occupied with agricultural inquiries and my heart has been long and deeply interested in the improvement of the farming art and the farmers themselves. My habits through life have called me to mingle with them constantly. There is no rural or agricultural labor with which I have not been familiar. My enthusiasm in the cause of agricultural improvement has never in the slightest measure flagged or abated. I know no more reasonable or useful object to which I can devote the power of doing any thing for my fellow man which Heaven has given me. With these sentiments I enter upon a new field of enterprise and labor; and I shall be happy to do what I can to enrich and adorn it, and to render it more and more productive.

I have often thought, indeed I think every day of my life, what a curious process this writing and printing is; and I never receive a letter but I look upon it as a kind of standing miracle. When Capt. Smith was threatened with death by the Indians in Virginia, he was released by the interposition of Pocahontas upon a condition that he would give a certain amount of arms or ammunition for his ransom. To obtain these he must communicate with his friends. In order to do this he wrote a few lines upon a leaf torn from his pocket book and having sent this by a messenger to his friends, the ransom was immediately paid. The Indians looked at this proceeding with unutterable astonishment. What indeed can be more astonishing than that by a few scratches, a few black marks, a few mystic characters, we can communicate with each other as effectually as if we grasped each others hands or looked in each others eyes; that we can tell our thoughts, feelings, purposes, history, with certainty and precision, though those with whom we communicate may be hundreds and thousands of miles removed from us, though mountains may raise their inaccessible summits, and oceans spread their unfathomable depths between us; that we can live indeed after we are dead; achieve as it were an immortality on earth; and transmit that which shall materially affect men's condition, their subsistence, conduct, virtue and happiness, far on the line of time, with generations yet unborn, who never knew us nor ever heard our names.

But it is not merely the wonder workings of this wonderful invention that impress us; but there is connected with it a moral responsibility that is most serious. Whoever wields a pen wields a powerful instrument for evil or for good, indeed in many cases far more powerful than the sword of the victorious hero, leading on his thousands to conquest. The martial victory may be soon forgotten; the blood-stained field be cleansed; and the field covered with the dead and dying become again verdant and waving with the beautiful products of the husbandman. But what is written is written, and cannot be taken back. It must remain to work its effects as much in the end as the beginning; and how long and to what extent no human

sagacity can predict or even imagine. It is said to the singular praise of one that he never wrote a line, which "dying he would wish to blot." This is a most covetable eulogy, and happy, thrice happy shall I be if I can but approach so happy an honor.

The New Genesee Farmer has two objects; to improve the soil and to improve the man. To illustrate the best modes of culture by precept, by example, and by experiment; to treat of plants and products, soils and manures; of the influences of light and heat and rain and dew and frost; of farm stock, farm buildings and implements, and every thing connected with husbandry and domestic economy. This will be its first object. The second will be to treat of all such useful knowledge and inventions in the mechanical departments as will be particularly interesting to farmers, the tillers of the earth, and persons dwelling in the country and interested in rural pursuits. The third will be to treat of markets and trade and commerce, and all facts and laws bearing upon these subjects as far as they concern that particular class in the community to whom the paper is mainly addressed. The fourth object is the moral improvement of the young and of the rural population generally; and if possible to render the profession of agriculture attractive and respectable. As we claim for it to be the most important of all pursuits, vitally affecting every condition in society, so we wish to see it not exalted above any other respectable profession in the community, but not degraded and disdained as it has too often been; and taking its proper rank with the first and best.

These are the general objects and views by which I shall govern myself in the conduct of this paper. I shall not now enter into details. The New Genesee Farmer has not now character to establish. By the ability and intelligence with which it has been conducted it has already obtained a wide circulation and has been held in high esteem. I am happy to say that I am not to be deserted by those, who have hitherto served in its ranks. I shall do what I can therefore to maintain its character and to extend its usefulness. Besides the co-operation of those, who have hitherto contributed to its columns, I am promised other and most valuable aid, from some of the best minds in the country; and from such co-operation in a cause so important we may anticipate the best results. I have many more things to say in relation to these matters; but I will not extend my editorial at this time; and these matters will come in various forms and on other occasions.

It has always been common in the clerical profession to preach on the Sunday after their ordination on the duties of a minister. A very shrewd friend and one of the best of men said to me that he took care after his settlement not to do this, lest he should come short of his promises, (as who in an untired case does not) his people might not forget to remind him of what he promised. Perhaps it would have been wise in me on taking my seat in this editorial chair to have said nothing; but having said what I have, I shall after this avowal have, in a due regard for my word, very strong motives to act upon the principles, which I have laid down.

HENRY COLMAN.

IMPROVED STOCK.

Ayrshire, Durham and Native.

Lewie F. Allen, Esq., of Buffalo, in an elaborate article in the Albany Cultivator of May or June last, which I have not at hand, was pleased to attach some remarks which I had made on the subject of Dairy Stock at one of the Agricultural Meetings held in Boston the last winter. Many of my friends said on reading the piece, "You will answer Mr. Allen, certainly?" But said no I am not about to take off my coat and turn up my sleeves and go to fistfights with an old friend. I grant that the letter appeared very civil, and had several gentle passages in it; but these fine touches reminded me of the remark of a Frenchman in relation to another person in a case somewhat similar. "Ah! bien; he von ver civil man; he make von, two, tree bow; he say, perlez vous, monsieur, and (crossing his fingers over the back of his neck) then he cut you off behind." I saw the drift of the letter. My friend Allen's coffee was not sweetened that morning, and he determined to challenge me to single combat. He began by putting me in the opposition. But I am not opposed to him in this matter; I never have been; I am not the enemy or undervaluer of the Improved Durham Short Horns, but I say only that we want the proof that they are the best milking or Dairy Stock among us; and that they are the stock best adapted to the New England pastures and the habits of our New England farmers. Mr. Allen's statement that Mr. Powell had a Short Horn Cow which had made 22 lbs. of butter per week is, I apprehend, a mistake, as no such case has been given to the public by Mr. Powell within my knowledge, and he probably refers to the cow Belina, of which I have given an account in the subjoined notes. Now I have only to add that I am a peaceable man, and do not accept my friend Allen's challenge; but I have gone to work quietly to collect all the facts on the subject, which I could find; and laying them honestly before the farmers, they, as good men and true, will I have no doubt render an honest verdict. Now gentlemen I stand together and barken to your evidence.

H. C.

(From Mr. Colman's Fourth Report on the Agriculture of Massachusetts, now in press.)

Dairy Stock.

Middlesex county, though very poorly suited to grazing, and on account of the high prices of all cattle feed, not at all adapted to the raising of stock, has yet several individuals of intelligence and public spirit engaged in this patriotic object.

Some years since, (about 1830,) a number of gentlemen associated for the purpose of establishing a stock farm, and purchased in Charlestown a valuable property for this object. "It was proposed to establish a stock farm in the vicinity of Boston, devoted to the important objects of breeding and rearing the best breed of horses, neat cattle, sheep and swine; the rearing and selling on commission all kinds of live stock; and combining also with these the business of agriculture and horticulture, upon the most approved and economical system. This farm consisted of 222 acres, was made up of a variety of soils, and was well adapted to the purposes either of summer or winter feeding of animals, yielding a great quantity both of English and salt hay." Samuel Jacques, a man well experienced and of excellent judgment in these matters, took the farm with this view; and has succeeded, by judicious selection and crossing, in rearing a milking stock of extraordinary valuable properties for the dairy. Of this stock I gave a full account in my Second Report, and, as far as appears, there is no reason to withdraw the commendation there bestowed on them. Their cheese properties have not been tested; nor have I been able to ascertain the quantity of milk afforded by them in any given time; but the quality of their milk for butter is not surpassed by any animals which have come under my observation. There can be no doubt that cheese from their milk would correspond to its superior quality. Mr. Jacques informs me that they still maintain their excellent character in this respect. My only regret is that I have not been able to induce him to make such continued experiments of their yield in milk or butter, for a week,

or month, or three months, as would warrant me in speaking with more confidence. Without my personal reference whatever, I may be allowed to say that in my opinion, intelligent farmers, who have valuable animals, owe it to the agricultural community to make such trials as will fully test their distinguishing properties. All conjecture and guess work in this case ought to be utterly rejected. The trial of a day or week is a small matter, and will seldom warrant any confident conclusions. In the case of a valuable cow or race of cows, the age and condition of the cow should be noted, her local and pedigree, her feed and treatment, with the utmost particularity; the times of milking, and the amount yielded for one, or two, or three months, in pounds and in cubic measure; the actual amount of butter or cheese produced in the time, and the quantity of milk and of cream required to make a pound of butter or of cheese. There may be some trouble in making these observations and experiments, but the satisfaction of this exact knowledge is an ample compensation for any trouble which it might cost. I am compelled to say, that in respect to most of the statements which men make in regard to their stock, unless they are founded upon such exact measurements and observations continued for a length of time, no reliance can be placed upon them.

Another breed of cows has been introduced into the country, from which great improvements in the dairy have been anticipated. These are the Ayrshire, the most celebrated dairy stock of Scotland. The Massachusetts Agricultural Society, with that eminent liberality and single desire to advance the agricultural interests of the community which have always marked all the proceedings of their board, imported an Ayrshire bull and three cows. The gentleman empowered to select them was well qualified for that object, and took particular pains to carry the patriotic designs of the society into effect.

The bull has been placed successfully in different counties of the State, and the cows distributed with different individuals, viz. C. B. Baker, of Medford; Elias Plimney, of Lexington; and Daniel Webster of Marshfield.

John P. Cushing, of Watertown, whose public spirit and regard for the agricultural interests of the country have been displayed in the management of his farm, in the importation of some of the best animals from abroad, and the gratuitous distribution of their progeny among the farmers with a view to improve their stock, has likewise imported some of the finest animals, which skill and money could select, of the Ayrshire stock.

It does not lie in my way to go into a history of this stock in this place. They are generally agreed to be the best dairy stock in England. They are reputed to yield large quantities of milk, and produce large amounts of cheese and butter; besides keeping themselves in good condition and being easily made ready for the butcher. The cows are eminently beautiful. In size, however, and symmetry, they are decidedly inferior to the improved Durham short horns; but there is good reason to think them a harder race of animals.

From some of the gentlemen to whose care the society's animals were committed, I have been unable to obtain as full information as is desirable. Mr. Webster's forman, in his absence, informed me that the cow was quite superior as a milk cow. Mr. Brooks says, "My cows give about the same quantity each, but I cannot boast of their doing like mine which I have heard of. My Ayrshire does not, I think, give more than thirteen or fourteen quarts at best, and the milk is rather than others with the same feed. It is, however, a valuable race in our State, as doing well in our common pastures, and not running to fat like some. They are very gentle."

Mr. Plimney, in a recent letter, thus writes:—"I have given the Ayrshire stock a pretty fair trial, considering my limited means,—enough however to satisfy me of their valuable dairy properties, and of the capacity for enduring the cold winters and short keep of the northerly part of the country. In the month of June, 1830, I selected from twenty cows my best native cow, for the purpose of making a trial with my Ayrshire cow as to the quantity of butter each would make. My old pasture, for I had then done little to improve them, afforded but a very short time of grass. These two cows ran with my other stock, and had no other food than what they could get in these dry pastures."

The quantity of milk from the Ayrshire was not greater than that from my native cow; but the Ayrshire made nine and three-quarter pounds of butter in a week, while the native cow in the same time made but eight and a half pounds; besides, the quality of the butter from the Ayrshire cow was decidedly better

than that from my other cow. The trial was made with great care, and the correctness of the result may be relied on. The Ayrshire cow has been kept with my other stock and inclined to do better than the rest; still she appears to better than any of my other cows, and endures the cold of winter quite as well. She has given me three fine calves; the first a bull, which I now have, a very fine animal; the second I sent into the county of Essex, and is owned by Mr. Malsland of Andover, and at the cattle show in that county in 1830, the first premium, offered by the State Society on bulls was awarded to him. The third is a heifer, now little more than a year old, and is a beautiful creature. Upon the whole, from the little experience I have had, I cannot doubt that the Ayrshire, for its dairy properties, is greatly superior to the Durham for this part of our country."

Mr. Cushing has been kind enough to favor me with an exact account of the produce of four Ayrshire cows on his farm for the times therein specified, which I here subjoin:

1. Memoranda of Milk given by imported Ayrshire cow Flora, for one year, 1837.		
From 17th of May to 1st of June,		608 lbs.
" 1st of June to 1st of July,		1192 "
" 1st of July to 1st of August,		1064 "
" 1st of August to 1st of September,		811 "
" 1st of September to 1st of October,		718 "
" 1st of October to 1st of November,		489 "
" 1st of November to 1st of December,		469 "
" 1st of December to 1st of January,		432 "
" 1st of January to 1st of February,		412 "
" 1st of February to 1st of March,		383 "
" 1st of March to 1st of April,		484 "
" 1st of April to 1st of May,		419 "
" 1st to the 29th of May,		242 "
		7728 lbs.

At 10 lbs. per gallon, 772 gallons.

2. Memoranda of Milk given by imported Ayrshire cow Juno, for one year, 1837.		
From May 23d to June 1st,		843 lbs.
" June 1st to July 1st,		796 "
" July 1st to August 1st,		845 "
" August 1st to September 1st,		690 "
" September 1st to October 1st,		475 "
" October 1st to November 1st,		513 "
" November 1st to December 1st,		318 "
" December 1st to January 1st,		394 "
" January 1st to February 1st,		401 "
" February 1st to March 1st,		326 "
" March 1st to April 1st,		338 "
" April 1st to May 1st,		216 "
" May 1st to 7th,		30 "
		5367 lbs.

At 10 lbs. per gallon, 536 gallons.

3. Memoranda of Milk given by imported Ayrshire cow Emma, from June 20th to May 21st.		
From 20th June to 1st July,		283 lbs.
" 1st July to 1st August,		805 "
" 1st August to 1st September,		623 "
" 1st September to 1st October,		567 "
" 1st October to 1st November,		498 "
" 1st November to 1st December,		319 "
" 1st December to 1st January,		403 "
" 1st January to 1st February,		406 "
" 1st February to 1st March,		351 "
" 1st March to 1st April,		319 "
" 1st April to 1st May,		319 "
" 1st May to 21st,		151 "
		5163 lbs.

At 10 lbs. per gallon, 516 gallons.

4. Memoranda of Milk given by imported Ayrshire cow Cord, from Nov. 17th to May 21st.		
From November 17th to December 1st,		388 lbs.
" December 1st to January 1st,		834 "
" January 1st to February 1st,		846 "
" February 1st to March 1st,		776 "
" March 1st to April 1st,		704 "
" April 1st to May 1st,		670 "
" May 1st to 21st,		405 "
		4623 lbs.

At 10 lbs. per gallon, 462 gallons.

The mode in which these cows are fed is as follows: "Our Ayrshire cows, during the winter, have half a bushel of sugar beets or potatoes; with the former, about a pint of dry meal mixed with the cut beets; but when they have potatoes, the meal is omitted.—With the above, they have as much English hay as they can eat. In the summer they have nothing but what they get in the pasture. They are driven, more

ning and night, from the pasture to the barn to be milked, and after that operation are driven again to the pasture.*

In addition to these statements, I am favored with an account of the produce of an Ayrshire cow imported and owned by George Randall, of New Bedford. His letter to me is as follows, dated Sept. 9, 1841:

"My thorough-bred full-blooded Ayrshire cow Swinley, was imported by me from Scotland in 1839. She was six years old in May last. She calved on the 31st of last March. She was milked regularly three days previous to dropping her calf; and had drawn from her in the time from 45 to 50 quarts. Commenced setting her milk for butter on the 1st day of April. The milk was not allowed to touch a tent, was fed on new milk for nine days, and after that time on skimmed milk. In all April, the quantity made from her was 43 lbs. 6 oz. The quantity in May was 42 lbs. 1 oz. In this month her milk decreased. Quantity in June was 44 lbs. 7 oz. In July and August, her milk was not kept separate from that of other cows. Weighed her milk [for one day, H. C.] on the 7th of April; it weighed 43 lbs. 9 oz. On the 2d of September commenced weighing her milk; in four days it has averaged 25 lbs. 8 oz. and has made in four days just five lbs. of butter. My pasture through the season has been very poor and short, owing to the dry weather and having too much stock for the quantity of pasture. From the time this cow was turned to grass until this day, (30th Sept.) she has had by measure two quarts of Indian meal per day regularly."

The Ayrshire bull belonging to the Society has been kept in Berkshire, Hampshire, and Worcester counties; and a fair opportunity will soon be had of testing the qualities of his stock. One of the best farmers in Berkshire county, speaks to me of their promising extremely well. In my opinion, the only certain test of the dairy properties of a cow is in the milk pail and the churn.

Of the Improved Durham Short Horn race, we have undoubtedly had some of the best animals ever bro't into the country, both with high aristocratic pedigree, and without pedigree, of uncertain and plebeian origin. In some parts of the country, large expenditures have been incurred in the importation of this stock; and Admiral Coffin, of the British Navy, in grateful remembrance of the land of his nativity, presented to the Massachusetts Society several fine animals of undoubted pedigree of the improved Durham short horn race, which were some time kept for the improvement of the breed. In addition to these, we have had a valuable bull imported by a merchant of Boston, understood to be the sire of Mr. Jaques's cream-pot breed; and the superior bull "Bolivar," imported by John Hare Powell, of Pennsylvania, from J. Whitaker's stock in England, celebrated for its extraordinary dairy properties. This bull was the finest animal of the kind which I have ever seen. A full-blooded short horn bull (Denton) was likewise imported into Worcester county, whose progeny has been highly esteemed. Several other animals of the same breed have been imported and kept in the State; and their blood has been considerably diffused throughout the country.

In point of size according to their age, in respect to growth and proportion of form, these animals are in my opinion not surpassed, indeed, not equalled, by any which have come under my observation. The Herefords are extremely beautiful; in neatness and fineness of form perhaps superior to the improved Short Horns. The Dons are likewise, though considerably smaller in size, yield, in compactness of shape, in quickness of movement and muscular strength, and in softness of hair and beauty of coloring, to no other race known among us. They are the prevalent race of our country; and in an extraordinary instance, when I had the singular pleasure of seeing three hundred yoke of these cattle—that is, all more or less of this breed—in one team, in Connecticut, I could not resist the conclusion that a finer team, of the same number of cattle, could not be found in the whole country. I am ready to admit that I have seen some fine yoke of oxen of mixed blood, of the Improved Durham, as fine in appearance, and in reputa-

tion as good animals for work, as any that I have met with; and some individual animals of the Improved Durham Short Horns, both pure and half blood, bullocks, oxen, and cows, which all points have been considered, have surpassed any thing which I have seen. They have approached as nearly to what I imagine the perfection of form in this race of animals as is to be looked for. With good keeping, they come early to maturity, and attain a large weight. The butchers, however, whom I have consulted, give it as their opinion, that they do not follow so well, in proportion to their size, as our own smaller cattle. In my observation, no animals degenerate sooner under neglect and poor keeping; and they require extraordinary feed and the most careful attendance to keep up their character and condition.

The progeny of Bolivar, from some of our best native cows, according to the testimony of a farmer who probably has been more successful in stock than any other man among us, have not proved remarkable for milk or butter; to use his own expression, "they are, upon the whole, above mediocrity." The progeny of Cerebus has been quite various; in some cases very good, in others inferior. Mr. Jaques is of opinion that the excellence of his cream-pot breed is principally to be ascribed to a cross with Cerebus, but on what rational grounds it is difficult for me to discover. Their beautiful color is certainly derived from the dam; and as the distinguishing feature in this stock is the richness of their milk, and this being precisely the quality for which the dam, the Haskins cow, was distinguished above all others, and it not appearing that any stock of Cerebus but when connected with this cow has ever been remarkable for this quality, it would not seem difficult to determine on which side of the house this excellence belonged.

So much sensibility exists in reference to this subject, the dairy properties of the Improved Short Horns, and so much of private interest and speculation is now mingling itself in the judgments which are formed or the opinions given in the case, that, if it is not difficult to speak with calmness and sobriety, it may be unreasonable to expect to be heard with candor and impartiality. My business is however with facts; and having no prejudices of which I am conscious to warp my own views, I shall, as fairly as I can, state those facts which have come generally within my own observation, and leave the conclusions to the honest judgment of my readers. I have already touched on this subject in my First and Second Reports, and the reader will not have a full view of the case, as intended here to be presented, without a reference to them. As to what these cows are stated to have done abroad, it would lead me too far to treat much of that here. When a bull will bring at a public sale one thousand guineas, cows more than four hundred guineas each, and heifer calves over one hundred guineas apiece, we may infer that guineas are more abundant than with us. It would not be an unreasonable suspicion that a fever of the same type which prevailed so alarming a degree among us in 1835-6, &c., and known here as the *multicaulis fever*, may have infused itself into the veins of some of the bidders and competitors of these occasions.

It may be promised that a very large number of these animals have been brought to this country, and some of the highest character, both as to pedigree and attested merits, since persons of the greatest skill have been commissioned to make the purchases, without any restriction as to cost or expense of transportation. As early as 1825 fifty-six of these animals, all of them of high blood, had been exhibited at the cattle shows in Pennsylvania, and before and since that time large importations have been made into Maryland, New York, Ohio, Connecticut, and Massachusetts.* I have seen large numbers of these cattle, and have to regret that I have not been able, after repeated private and public solicitations, to obtain more exact and authentic accounts of their products. From this backwardness on the part of the owners and importers I think there is reason to infer that some disappointment in respect to their dairy properties has been experienced. My belief is, that our expectations in this matter were too highly excited; and that qualities, for which some extraordinary animals among them were remarkable, I mean particularly the quality and yield of milk, were erroneously deemed invariable characteristics of the race. In a former report I quoted the opinion of a distinguished Scotch farmer, Mr. Shirreff, and the authority of a private letter from a competent judge in England. Shirreff pronounces them, in an off-hand way, "the worst milking breed in Britain." The private letter stated "that this breed of stock has not

been held of late years in great estimation for milking. Short Horns are only calculated for the best and most powerful hand; on poor soils they will do nothing."

To these I now add the remarks of Geo. W. Featherstonhaugh, in a letter to Mr. Powell, of Pennsylvania. Mr. Featherstonhaugh, from his acquaintance with the farming interests both in this country and abroad, will be deemed a competent judge. He says "the property of being very deep milkers, there is to be considered accidental, rather than one which can be continued with any certainty in the breed. Take one short horn with another, no breed is more valuable for its milk, or keeps in better condition under the same circumstances; or goes to heat at less expense; or furnishes more money and manure in a given time. In order to keep up these great qualities, we must remember that, in their native country, it is considered indispensable to keep them extremely well, and in a very different manner from the general custom prevailing here; which is, in summer, to leave cattle to help themselves to what they can find, even in the most severe frosts, and in winter, to let them a moderate quantity of hay and straw. In England, where they are less troubled with dry weather than we are, they have always green crops and roots to give them, and they give them in abundance. It is there considered that the higher this sort of keep the better the health of the cow, the richer her milk, the stronger her calf, and the greater the quantity and value of her dung. If all this provident attention be necessary in that moist climate, it is certain that the breed will degenerate with us, if it is not kept in high condition. Hot climates produce shallow milkers; and where exceptions occur, they get poor very fast when indifferently kept, and it becomes more expensive to recover their condition than to keep it up. The wear and tear of condition in deep milkers is very great, and is only to be checked by abundance of succulent food and roots; or, when these are not to be had, by occasional feeds of meal with their hay."

These remarks are so well founded and so much to the purpose, that I have given them at large. That this highly improved race of animals is of all others best suited to our climate, soil, mode of husbandry, and general condition, is a question I shall now pass over; but on the subject of the milking or dairy properties, I will give the most exact returns of which I have been able to avail myself, and shall subjoin an account of what we call native cows, that any one may compare them at his pleasure.

It may be said that the native cows to which I refer are all select animals. I admit that they are remarkable animals; some of them very extraordinary; but in respect to the large majority of them, I have met with them accidentally, and can find in the State thousands and thousands equal to them, if any part of them were done to their keeping. But the truth is, that in general, nothing can be more negligent and mean than the manner in which a large portion of our cows are kept.

On the other hand, it will not be denied that the Short Horns to which I refer, are selected and highly fed animals. It seems not a little remarkable among the many hundreds which have been brought to and produced in the country, if extraordinary dairy properties are the characteristic of the breed, as many of their advocates maintain, and when there is such an extreme eagerness to establish this point, that more of these distinguished examples should not have been given to the public.

Let us look, however, at the facts in the case, and make up our judgment accordingly. In all matters of inquiry or debate, or object should be truth, not triumph.

I. An improved Durham short horn cow (Belina), imported by John Hare Powell, of Pennsylvania, produced in three days 8 lbs. and 13 oz. of butter, which would be at the rate of 20½ lbs. per week. The cow was fed with slop of Indian meal, clover and orchard grass. She has yielded repeatedly by measurement, and so far as can be ascertained by the bucket, twenty-six quarts within twenty-four hours. One quart of her cream produced one pound five ounces and one quarter of an ounce of butter. In one case two minutes, in another case only three seconds, were required to convert the cream into butter.

The butter trial was certainly a short one, and it is to be regretted that it had not been longer continued.

"This furnishing more manure in a given time" is rather an equivocal recommendation! It has once happened to me to know a case where the sale of the manure at a very saleable more than paid for the cost of the hay given to the horses; and the litter was furnished gratuitously by the purchaser to the stable-keeper. I will save the reputation of the farmers in this case; the manure and litter were wanted for a particular use in the arts. This was certainly a novel and economical application of horse-power.

* When such farmers as Messrs. Plimney and Randall say of the former, "that his pastures afforded but a very short time of grass, and that there were two cows ran with his other stock and had no other food than what they could get in these dry pastures;" and the latter, that his pasture, "was so dry that his Ayrshire cow, was poor and short and was obliged to leave her calf to find a few twigs of grass, or overstocked," I cannot but have before me a very striking example for presenting such an evil example to their brother farmers, who are looking to them as fugitives. This is certainly the way they treat their other friends; nor are they at all suspected, from appearances, of subjecting themselves to the same penance. The general treatment of the cows in New England would not be an inapt subject of presentation by a grand jury.

* One hundred and fifty of Improved Short Horns and grade cattle were exhibited at the Fair of the American Institute in New York, October, 1841.

The quantity of milk was very great, though we are left at a loss whether it were wine or beer measure. If it were beer measure, one fifth is to be deducted to bring it to wine measure. The measurement of milk in the bucket is always a very uncertain measurement. This cow was a most extraordinary animal, and it were to be wished that we had returns from others of Mr. Powell's fine stock, and some particular information of the progeny of this cow.

2. The celebrated cow Blossom, an improved Durham short horn cow, owned by Mr. Cadby, in Delaware, is stated to have given in 1840, in one week, 247½ quarts of milk, or more than 35 quarts per day, from which were made 13½ pounds well worked butter. This summer, (1841,) two months after calving, she gave in one week 253½ quarts, or 36 quarts per day, which yielded 17½ lbs. of superior butter. On the 13th of July, fourth month after calving, the following is a record of one day's milking:—Morning, 13½ quarts; noon, 1½ do.; evening, 11 do. = 35 quarts. She gave 16 quarts per day up to the time of calving. This measure is understood to be wine measure. This is one of the largest products on record. In the first case it seems to have required 18 41-53 quarts to make one pound of butter; in the latter case, 14 45-63 quarts. This is a large amount. For the difference in the two cases it is not easy to account. The mode of her keeping is not stated with any explicitness. The owner of the cow is not known to me, either in person or by reputation.

3. My next account is from Pauli Lathrop, of South Hadley, in this State, a farmer distinguished for his intelligence and success, and on whose statements, made on his own knowledge or observation, entire reliance may be placed. I give an extract of a letter, which I have recently received from him:—

"We have now twenty-five head, which are thorough bred improved Short Horns, without the least mixture of other blood, and are, beyond question, as pure blood as can be produced. These animals generally possess great vigour, and are perfect in symmetry. At two and a half years of age, the heifers will average about 1200 lbs., and I have raised one bull calf which weighed 1020 lbs. the day he was a year old. Our stock has been fed upon grass and hay only, with the exception of a small quantity of roots in the winter months. One of our cows is sixteen and two others fourteen years old, and they now exhibit the appearance, so far as constitution is concerned, of being young animals, which I think is conclusive evidence of this race of animals being well adapted to our cold climate."

"They mature early and take on fat easily, and, in these respects, have a decisive advantage over our native stock. To test an experiment between a native and a short horn, I took a cow of each of about the same age, dried them from milk at the same time, tied them side by side at the same manger, and fed them both exactly alike on hay only through the winter. The result was, that the Durham, in the spring, had gained flesh and was in high condition, while the native was in only ordinary condition."

"Their product, in both butter and milk, is much better than I have ever been able to obtain from native cows with the same keep. We have one cow which made more than 12 pounds well worked butter per week in April last, and I have repeatedly converted the cream of this cow into butter in fifteen seconds.—She gave in June last, upon grass alone, 360 lbs. milk in a week, having been milked but twice a day, and the averaged 51 lbs. per day for two months. We have another cow which gave 43 lbs. milk per day through the month of June; and we have still another (now quite old,) which a former owner has assured me has given 28 quarts of milk per day. We have two heifers, with their first calves, which averaged 35 and 37 lbs. milk a day, through the month of June."

"I have tested the quantity of cream obtained from given quantities of milk from the above cows, and find it to be 1½ to 1¼ inch from 10 inches of milk. There are some persons who deceive themselves, and doubtless others who are guilty of deception knowing it to be such, in representing mixed blood Short Horns as 'full blood,' 'pure Durham,' 'thorough bred,' &c. Now it is not sufficient that an animal is called 'full blood,' or guessed to be the breeder of this race of animals, who understands himself, will require evidence of the fact, and such evidence as cannot be called in question."

4. Of the Short Horned cow Annabella, presented to the Massachusetts Agricultural Society by Admiral Coffin, E. H. Derby states, "that he has a perfect recollection of weighing her milk repeatedly in June,

when she had no other feed than what she obtained from the pasture; the milk, morning and night, weighed 4½ lbs. At the same time, we weighed the milk of a very fine native cow with the same keep, which gave 33 pounds. The greatest objection to them in my opinion, is, that they incline to go dry longer than our native stock."

I cannot agree with Mr. Derby in thinking the going dry a long time a constitutional feature in this stock. This circumstance depends not upon the stock but upon their treatment and keep; especially their treatment with their first calf.

5. A short horn cow, imported by F. Rotch, as I understand, then of Lecheville, New Bedford, and owned by C. N. Bennett, of Albany, a farmer well and deservedly known to the agricultural community, was one of the most beautiful and promising animals of the kind that I have ever seen; her pedigree undoubted and carried up to the highest sources. At my request, Mr. Bennett tried her capacities for butter, and in our week in September obtained 6 lbs.

6. A cow, owned by George Johnson of Lynn, of whose pedigree, after much inquiry, I can learn nothing, but whose genuineness as an improved Short Horn I have no doubt, it not of full blood yet very high bred, has produced this season, from 12th March to 12th September, (six months,) 7100 lbs. of milk, averaging 15 beer quarts of milk per day for that time. She is now (November, 1841,) giving at the rate of nine quarts per day. Her feed is now one bushel of mangel-wurzel and half a peck of wheat bran per day, with what they will eat. The butter properties of this cow have not been ascertained, as her milk is sold daily by the quart. She is a superior animal, both in appearance and production.

7. Wm. K. Townsend, of East Haven, Connecticut, had eighteen cows of the Durham Short Horns, full-blooded or in part, which were kept for supplying milk to the city of New Haven. These, in milk, gave a daily average of 110 quarts, besides the milk and butter used in the family. It will be at once perceived how indefinite this account is, though given by the intelligent committee of the New Haven Agricultural Society. We are at a loss to know how many cows were in milk at a time, whether all or a part only, and how much butter and milk were used in the family. The family, it is said in another place, was large.

I have had the pleasure of seeing this remarkably beautiful stock. Their appearance was in the highest degree favourable to their character and keeping. The average return of milk, as above, was 629 quarts per day, exclusive of the required quantity.

8. I subjoin an extract of a letter from one of the most intelligent and public spirited farmers in New England, Henry Whitney, of New Haven, giving an account of his Improved Short Horn stock.—Perfect reliance may be placed on it, and it will be read with much interest. Mr. Whitney's personal improvements in agriculture and gardening, his liberal expenditures in his importations, with a view to improve our live stock, and the intelligent and efficient aid which he is rendering to the great cause of an improved husbandry, entitle him to the grateful respect of the agricultural community. Many men are like the spinules in a factory, which make a great deal of buzzing and racket, yet perform a very humble part. Mr. Whitney, without noise or ostentation, moves with the force of a power wheel. He turns the spinules, while the little things, with their heads always raised, imagine that they fly round of their own accord. Those who would give honor to whom honor is due, it is not worth while to overlook them. They perform their part well, and their operation is essential. The Connecticut agricultural loan is now turning out many a beautiful and substantial fabric.

"I have never kept an accurate account of the milk given, for any particular length of time. The calves generally have been allowed to suck until three or four months old, after which it was given to them from the pail until 8 or 9 months had expired."

"I have imported four cows, all of which were carefully selected in England, and at high prices.—They have all produced one or more calves since I have owned them, and with one exception they have been dropped in winter. Strawberry, a cow you saw at Northampton, calved in July, 1840, and I carefully measured the milk from each soon after calving, and they have averaged from 22 to 29 quarts per day. Betsey, the first cow I imported, gave in January 1839, soon after calving, 29 quarts, and 1 month afterwards, she was giving 20 quarts. Her milk was only of a fair quality. She continued to milk very largely until within a few weeks of slipping her calf, which occurred about the 7th or 8th month after tak-

ing the bull, when she again increased, and afterwards diminished to 16 quarts."

"My second cow, Violet, gave, after calving, 24 quarts of very rich milk, and continued to milk deeply for three or four months, when the quantity was diminished to 10 or 12 quarts per day."

"My third cow, Strawberry, gave by measurement 22½ quarts of milk on the grass she could pick from my short pastures. Her milk was very rich and yielded a large amount of butter, though I cannot say accurately how much, as it (the milk) was not all brought to the house, and a fair proportion was used for ordinary purposes in the family. Mr. Lathrop, on whose farm, at Hadley, she remained four or five weeks, wrote to me on her return as follows:—'I must speak in the highest terms of Strawberry for a milkster, and butter cow. As for size and shape, she speaks for herself.' She is without doubt, a very superior cow. She was at Hadley in October, 1840."

"My fourth cow, Ringlet, calved about a year since, producing twin heifers. She was milked twice or four times, giving from 10 to 12 quarts each milking, when she fell sick with the milk fever and was two or three weeks before she recovered. During her illness she bruised one of her teats so badly, that she has lost the use of it. This cow is undoubtedly the best milk cow I have; but as the calves have sucked her until within a very short period, I cannot give my particulars. She is now five months in calf; her twins are one year old, and she gives now from three teats 8 quarts per day. You will please understand that I measured the amount with care, full beer measure, purposely for my own gratification and without getting any extraneous for the purpose of increasing the milk."

"My cows were fed in winter on cut straw with corn or oat meal mixed—say half a peck of corn meal to 4 bushels of finely cut straw and about 2 quarts of oat meal added. About a bushel was given to each cow once a day, and 3 pecks of turnips or rutabagas twice a day to each, besides a little hay. This was my feed when they were in the greatest flow of milk. In summer they are out at pasture, and when it is short, corn stalks and other green feed are given to them.—On our dry soil, however, it is difficult for the Durhams to thrive when the summer droughts commence. They suffer, too, much from the heat and from the stings of flies, which almost set them crazy. They stand our winters fully as well as our common cattle, and put on flesh very rapidly at that season, if well fed."

"My calves, at a year old, weigh from 70 to 1050 lbs.; and I feel confident that a thorough bred Durham steer can be made to weigh as much at three or four years old, as a common steer at five or six. There are certainly objections to the breed where pasturage is short and a full supply of hay is not given. They are greater consumers than the common cattle of the country, but they are of much greater size, and, as said before, mature much earlier. My cows are mostly udder-bred animals, thorough bred. I enclose you the pedigrees in full, of Strawberry, Ringlet, and Violet, as requested."

9. Cow. Levi Lincoln, Worcester, 1825. A cross from Denton on a superior native cow. "This cow has often given from 24 to 27 quarts of milk per day of excellent quality, yielding a large proportion of cream. The least quantity of milk given by her in any one day during the summer drought, on grass-land only was 13 quarts." [Mr. Lincoln states to me that this was her measure.]

"For the dairy and the stall, he speaks with the utmost confidence of the pre-eminence of Denton's stock. One of his 3 year old heifers (a half or three fourths blood) gives from 16 to 29 quarts of the richest milk by the day since calving; the other a little less, from the circumstance of having been in milk continually for more than a year; but her milk is in no degree inferior in quality. The last season she gave eleven quarts at a milking, with grass only, and this not unfrequently."

Mr. Lincoln likewise states to me, that on putting six of our best native steers, purchased from Vermont, and six others of the mixed blood of Denton into the same open yard in the fall, and keeping them through the winter at the same manger, on the same feed, and in the same exposure, the growth and condition of the mixed bloods in the spring were greatly superior to those of the native stock."

10. Cow. Dolly. George Hood, Lynn. "Dolly had her first calf in April, 1833, before she was two years old. In the following June she gave 14 quarts per day, measured a number of days in succession, and made 10 lbs. and 2 oz. of butter per week. She calved in October, 1839, and from the 15th of that month to April 13th, 1840, 180 days, she gave 16 quarts per

*To have made the trial exact, the two cows should have been weighed at the beginning and end of the experiment. Their food likewise, should have been weighed at least for a portion of the time.

day, which sold for \$180. In January, 1840, she gave 565 quarts measured out, averaging over 18 quarts per day in the coldest winter month, and three months after she calved. Some days in that month she gave 204 quarts per day. She calved again in December, 1840, and from the 17th December, 1840, to July 11th, 1841, (212 days), she gave 3004 quarts milk, being 11 1/4 quarts per day for seven months, which was sold for \$168.67. Her milk is rich and makes delicious butter.

"She is used to three pecks of sugar beets and carrots per day, with good hay, and in the coldest weather a bucket of warm water with a quart of shorts in it. Dolly is remarkable for transmitting her milking qualities to her offspring. Three of her calves have been raised here, and they are all great milkers. One of them, called the Countess, gave last winter 14 qts. per day for some months after she calved, being four years old. I have a heifer from her, 15 months old, and a bull 11 months old from Dolly, both sired by Wycomet from Mr. Wells's stock. They are fine milkers, and I expect to get a good stock from them.

"Dolly's color is light red, with a few white spots. She has the fine mellow skin, beautiful proportions, and majestic mien, peculiar to the noble race from whence she sprung."

11. Cow. D. N. Breed, Lynn, 1841. This cow is supposed to be one-fourth of the Durham blood -- (one subject is given as her product:

The Colonial Farmer,
devoted to the Agricultural Interests of Nova Scotia,
New Brunswick and Prince Edward's Island. Vol.
1, Nos. 1 to 5, November, 1841.
We are glad to welcome this new recruit to our
ranks. We care nothing for geographical or political
issues where the great interest of the common brother-
hood of mankind is concerned; and that interest is an
improved Husbandry. One of the king's of England
shed to see the time when every one of his subjects,
even the meanest and humblest, should have when he
eaten, a roast fowl smoking upon his board. So
could we as far as possible multiply the products of
the earth, and extend their full enjoyment to every
one that labors for them. We rejoice therefore in
thy effort, wherever and however made, to make the
earth more productive, so that plenty and comfort may
rule where prevail; and then we should desire such
reform in the political institutions of all countries,
at they who by their sweat and toil produce the
wealth should be first served; and that all those politi-
cal contrivances should be abolished by which bread
so often intercepted in its way to the laborer's mouth,
he is left to starve in the midst of abundance.
Nova Scotia has great agricultural resources. John
Young, a few years since, in 1819-20, in his letters
described the assumed title of Agricola, pointed these out
the Nova Scotians in an admirable manner; and
used a spirit of improvement, whose vitality and ac-
tivity are attested by this publication, and by the es-
tablishment of the Dartmouth Agricultural Society,
the head of which they have placed a zealous and
efficient advocate of agricultural improvement, our
respected friend John E. Fairbanks.
Agricola showed that the agricultural resources of
Nova Scotia were abundant; that her soil was adapted
the production of the finest of wheat and the best of

stock; and that she had at her very door, in her gym-
nasium and line, the most sure elements of success. The
redeemed salt marshes on the shores of the Bay of
Fundy, converted by drainage and dyking into most
productive mowing and arable lands, have long been
celebrated as among the finest triumphs of agricultural
skill. Potatoes likewise must always be a great
crop in the productions of this country. Their cold
and moist summers and their calcareous soil are pecu-
liarly favorable to this plant; and we award to the
Nova Scotian potatoes the palm of excellence above
all others, which we have eaten. We have cheerfully
paid a dollar a bushel for these "white blue noses" in
preference to buying our own at twenty-five cents.
The directions given in the 5th number of the Col-
onial Farmer respecting the cultivation of potatoes,
have somewhat amused us, where it is advised to have
salmon lines stretched across the field, in order to
make the rows straight, &c. &c. This is a little too
much in the *kid-glove* style of agriculture. A good
Scotch ploughman, of which we know there is no
want in Nova Scotia, would with his plough open a
furrow for the planting in a tenth part of the time, as
straight as any fishing line could be drawn even with
a spermatic whale at one end of it.

The paper is well got up. It is filled principally
with selected matter, which is well chosen. We,
though liable to the same charge, object strongly to the
size of the type, as quite too small and crowded.
Much of a farmer's reading must be done in the even-
ing. He will be repulsed, when the type used is so
small as to try his eyes severely. We are of opinion
that in our anxiety to give our readers the worth of
their money, we crowd a great deal too much matter
into our periodicals. It is very much like filling a
liquid measure to overflowing for the sake of showing
that we are not mean, where all that runs over and of
course is spilled, impoverishes ourselves without ben-
efiting our customers.

"The Orchardist's Companion."
The three published numbers of this splendid work
have been received. It is quarterly, and each number
contains twelve colored lithographic plates, and more
than twice that number of pages of letter press. The
editor and proprietor is A. Hilly, 41 Chestnut street,
Philadelphia.
The figures of the fruits, as paintings, are the finest
that I have seen in any work of the kind. But as ac-
curate representations of individual varieties, they are
deficient, especially with regard to coloring. As this
part of the work is doubtless committed to other hands,
it should receive the more careful supervision of the
editor, or every copy may differ from the original, and
from other copies. Except this care is taken, engrav-
ings will lose in correctness all they gain in splendor,
by coloring. Some old acquaintances represented in
the work, I should hardly have recognized, as for in-
stance, the Washington plum, Prince's Yellow Har-
vest, and the Early York peach; while others, as the
Peach Apricot, and Black Tartarian cherry, are admi-
rably executed in every point of view. But other
copies may vary. All the fruits are represented with
the branch and leaves, and are drawn with much taste.
But the reader must not expect to see equal taste in the
written part of the work, which however contains
many valuable remarks, which are accompanied with
some excellent original communications.
To represent fruit in such a manner as to assist in
identifying the varieties, such only for copying should
be selected, as are a fair average of fine specimens; and
not, as in the present instance, the very finest that
could be found. This may be one reason why some
old well known fruits appear so differently from what
we are accustomed to see, when they are only in their
woman, every-day dress.

But with all its inaccuracies, the work is a noble effort
in the cause of American Horticulture, and no amateur
should be without it. Its cheapness, considering its
style of execution, is worthy of commendation. The
best edition, each number containing twelve colored
plates, is seven dollars a year. The secondary edition,
each number containing only three colored plates, but
otherwise identical with the best, is three dollars a year.
The first furnishes the plates for about fourteen, the
latter for twenty-five cents, each, and the letter press
besides. J. J. T.

New-York State Agricultural Society.
The annual meeting of the New-York State Agri-
cultural Society will be held at the Lecture Room of
the Young Men's Association, in the Exchange, in the
city of Albany, on WEDNESDAY, the 19th of January,
1842, at 10 o'clock, A. M. The annual Address, by
the President of the Society, JOEL B. NOTT, Esq.,
will be delivered in the Assembly Chamber of the Cap-
itol, on the evening of the same day.

On the day preceding the annual meeting, (Jan. 18,) the
Exhibition of Butter and Cheese, together with
samples of Field Crops, will be held in room No. 10,
second floor of the Exchange, at which place must be
deposited, before 9 o'clock, A. M., all parcels offered
for premiums, heretofore published; and at 10 o'clock,
A. M., the several viewing committees will commence
the performance of their duties. The following are
the committees:

On Butter—Alex. Walsh and G. B. Richards of
Rensselaer, Robert Dennison of Orange, M. D. Bur-
nett of Onondaga, and J. M. Sherwood of Cayuga.

On Cheese—C. N. Bement and E. R. Satterlee of
Albany, John Caldwell of Orange, Benj. P. Johnson
of Oneida, and Samuel Perry of New York.

On Wheat, Rye, and Barley—Anthony Van Ber-
gen of Greene, Rawson Harmon, jr. of Monroe, Or-
ville Hungerford of Jefferson, William Parsons of Ni-
agara, and William A. S. North, of Schenectada.

On Indian Corn, Oats, and Potatoes—Henry D. Grove
and Henry Holmes of Washington, Howell Gardner
of Saratoga, Pomeroy Jones of Oneida, and Joseph
Hastings of Rensselaer.

On Root Crops—J. P. Beckman of Columbia, Francis
Roth of Otsego, G. V. Sackett of Seneca, John
Sanford of Onondaga, and L. B. Langworthy of
Monroe.

The above named committees are requested to meet
at the office of the Recording Secretary, (Cultivator
office), at 9 o'clock, A. M., on the 18th, at which time
the Executive Committee will proceed to fill any va-
cancies which may occur.

LUTHER TUCKER, Rec. Sec'y.
✂ Editors throughout the state are requested to
publish the above.

The American Almanac and Repository of
Useful Knowledge, for the year 1842.
Boston; published by David H. Williams. New-York;
Collins, Kears, and Company.

It would be difficult to name a more useful book
than this. It contains all the usual astronomical cal-
culations in any Almanac, together with a great
amount of other most valuable information of a statisti-
cal, political and general character, in relation to this
country and the world. This number, the 13th, and
the third of the New Series, contains the Agricultural
returns obtained by the Marshalls in taking the last
census. They cannot be relied upon as very accu-
rate; but as being as near an approach to accuracy as
can be expected. No man of intelligence, who is in
the world and means to remain so ought to be without
this book on their tables. As to those who choose to
live as the bears pass their winters, we have nothing
to say

Three Experiments in Wheat Growing.

MR. COLMAN.—When I commenced farming, some five or six years ago, having been previously engaged in mercantile and manufacturing operations, I was told by an esteemed friend, who was a thorough practical farmer, that if I intended to grow wheat successfully, I must in all cases plough my land THREE TIMES in summer following; for said he, "if you plough once, you will have 10 bushels, if twice, 20 bushels, and if three times 30 bushels per acre; this may not be the exact ratio, but it is near enough for a general rule." Well sir, I commenced in this way and had fair crops, and set down my friends advice as my golden rule.—my bed of PROCASTES, and I sawed of the legs and extremities of all other plans, until they fitted my theory. My land was a rather light soil, and I used clover and plaster freely; turned in the clover when in full blossom, and gave it two after ploughing.

My neighbor, whose land was of the same description as mine, and who practised the rotation of clover and plaster, used an entire different process; he took off from his field a clip of grass for hay, or sometimes pastured it till about haying time, when he let it grow till about the last of August or first of September; then he gives it a shallow perfect ploughing with a good green sward plough, turning every thing carefully under, and usually rolls it down; within a few days after, and sometimes immediately, drags it once and then sows his wheat.

I was quite determined that his crop should not be as good as mine, but what was my astonishment, when I observed, that from its germination to its ripening, it was as good or better than my thrice ploughed crop, and finally resulted in a greater yield per acre. I then gave it up, as I found others were successfully following the same course.

A little reasoning on the subject rendered the RATIONALE of the process quite apparent, especially on clean clover lays, free from all foul grasses. The young plant has the benefit of the first and entire decomposition of the rich, succulent herbage which was ploughed under; while in the other process of turning over and over, and consequent exposure to the sun, rains, and atmosphere, has its volatile parts more or less exhaled and lost.

Well sir, "thinks I to myself," my rule is infallible as to meadow and pasture lands, which contain June grass, red top, and other foul grasses, there can be no gainsaying that doctrine; but alas for the infallibility of general rules and specifics, and for the mutability of preconceived opinions. An acquaintance of mine is making good crops with once ploughing upon the worst kind of foul grass green sward the country produces, and with considerable less labor than the three ploughing process is enabled to do.

He commences at the usual time for summer following in June, and turns over his land in a good and husband-like manner, and not in the better skelter, hit-or-miss manner in which too much of our ploughing is done, by being run over as if you was riding a steple chase; but carefully and entirely turning every green thing fairly under. It is then left until he finds that the grasses begin to show life through the furrows, when it immediately gets a thorough harrowing, and so on, from two to four times, till the period of sowing, according to the dryness or wetness of the season, and the situation of the land; the surface is left in fine smooth order for mowing, free from those unsightly and troublesome lumps of undecomposed sods; and as far as my observation has gone, the grasses were as well got under as nine tenths of the lands followed by the old process, and is performed with much less labor; for with a good 30 tooth hinge drag, a team will go over from 6 to 8 times as much land in a day as they can plough.

Now sir, in these days of tribulation for farmers, from the depreciation of real estate and low prices of

the produce of the farm, "when we can't get a dollar a day for labor, and it is State Prison for stealing," it behooves us to look about our own interests, and if we can't get rid of our old habits of expenditures, which high notions and high prices have saddled us with, we should at least try if we cannot get our usual quantum of produce with LESS EXPENSE AND LABOR. If the saving of a crop of grass and once ploughing, will give as good or better return than the thrice ploughing process, let those who DARE depart from the old beaten track, try it.

Greece, Monroe Co., N. Y.

P. S. In your next paper I propose to give your readers my three experiments upon raising potatoes, and some of my notions about sorts, soils, productiveness, and their elementary value as a crop compared with the other roots.

AGRICOLA.

For the New Geneesee Farmer.

Ploughing Matches.

MR. EDITOR.—As ploughing matches are now considered an essential part of our Agricultural Fairs and are usually mentioned as that part which excites the most interest, it becomes a matter of interesting inquiry, why they excite so much attention, and whether they may not be improved so as to be still more useful and interesting? I have sometimes felt at a loss as to the cause of the intense interest with which thousands look upon a few teams ploughing, when that is the ordinary every day business of the farmer, and teams may be seen engaged in it almost from one year's end to another. An equal number teams engaged in the ordinary ploughing of the farm would scarcely arrest the attention of the traveller, and would perhaps only elicit a single remark, although greater skill were exhibited in the performance, and teams and ploughs better adapted to the work. It is evident that it is not the *rarity of the show*, nor the beauty or appearance of the teams or ploughs, for these are generally quite ordinary in appearance. Nor can it be in the work to be done; for the ground is usually the most unsuitable for ploughing which can any where be found. The work is beyond the capacity of the team—the plough is not adjusted to the soil, no opportunity being given for regulating the depth and width of furrow which an experienced ploughman is careful to do, and which requires some three or four hours to adjust right. The teams are frightened by the throng which surround them—the ploughman is excited and nervous by being the object of so much observation and remark. The word is given and off he goes at the top of his speed, his plough bounding from right to left and making more *balks* the first time through than he would make at home in a week. Generally the team which is most accustomed to noise and bustle, and the plough which is adapted to no work in particular, comes out first and wins the day.

As to the performance, the judges are saved all trouble of an opinion upon it, as the stamping of thousands of *loafers* obliterate all distinction of furrows.

The contest is over, the premiums paid, and who is the wiser for it: teams are over driven, the land is rather injured than benefited; no information is gained as to easy draft of ploughs, the ability to lay over a furrow or give it the requisite slope, width and depth.

No man is the wiser or better, except those who get the premiums, and they often pay dearly for their money by the harm done their teams. And yet multitudes go away highly pleased with the ploughing match and think it the most interesting part of the exhibition. Would they not be as well pleased had these teams been hitched to logs and drawn, to see which could draw the heaviest log with the greatest speed? And would they not be almost as much enlightened in the science of ploughing?

It seems to me that were our Agricultural Societies

to give this subject a little attention, our ploughing matches might be greatly improved. As in every other art, the watchword must be onward. But these matches are now managed just as they were twenty years ago. If we have made no improvement in using ploughs in twenty years, we have greatly improved the instrument. We have not now the same obstacles to contend with that we had then. Our farms are in a good measure cleared of roots, stump and stones. Therefore it ceases to be a recommendation of a ploughman, that he is skillful in dogging stumps—we require something more. What constitutes good ploughing? Verily, that the soil be equally broken to a uniform depth. This evidently cannot be done except the furrows be straight. For if crooked furrows there is an inequality in the width and of course some parts are more pulverized than others. Let, then, our agricultural societies require these three things in ploughing, viz: that the furrow be straight, and of uniform depth and width. And would suggest that the field be selected beforehand and that a competent committee determine what the depth and width shall be, by an examination of the soil, and let these be published as the rules of the match. If the field be in good condition for ploughing, and the crop that is to follow admit, I would name five inches for the depth and eight for the width and let the premium be awarded to the man who shall the most accurately comply with these requirements. Let ample time be given that the ploughman may go deliberately at his work, and I am greatly mistaken if these matches do not tend greatly to the improvement of ploughing in all its variations, or be equally interesting with those whose principal requirement is speed. Yours, &c.

MYRON ADAMS.

East Bloomfield, Dec. 21, 1841.

For the New Geneesee Farmer.

The State Fair and Western Cattle.

MR. EDITOR.—I observe that Western New York receives severe censures for not being better represented at the State Fair at Syracuse, but I think when all the circumstances are considered, it will seem that much of this censure is not deserved.

It is a fact that the farmers of Western New York are more in debt than those of the Eastern portion and when the times are as hard as at present, it cannot be expected that they can afford to spend as much time and money as would be necessary to take animals to that Fair. Let us, before we go further, see what would be the probable expense of taking one animal there, with an attendant, say from Batavia:—

Fare by Rail-Road to Rochester,	3 00
Expenses of man and beast in Rochester,	1 25
Fare to Syracuse on Boat and feed,	7 00
Expenses in Syracuse 2 or 3 days, say	5 00
Returning to Batavia,	11 25

\$27.50

Thus it will be seen that the expenses for one animal would be as much as the price obtained for 11 pounds of pork or beef. In this estimate no allowance is made for the time or services of the man who accompanies the animal, which would swell the amount to at least ten dollars more—making no inconsiderable sum, if it has to be made by raising pork or beef these times.

I have no doubt but that Western New York is completely with any other portion of the State in producing fine animals; and I for one should have gone that Fair and taken some stock without calculating expenses, had I found others in this country willing to do the same; but I did not like to be the only representative for old Geneesee.

If the farmers of this region had an opportunity like those of the East, for transporting their cattle to Syracuse free of expense, I have no doubt but that

the Eastern farmers would have gone home, minus at least one-half of their prize money. And here I would remark that the liberality of the managers of the Rail Road from Albany to Syracuse cannot be fully appreciated by the farmers of this state, and yet I am fully convinced that it was in the end redound to the advantage of the company, as will every thing which is done to increase the productive resources of the country. I hope the managers of the other rail-roads through the state will consider this subject, and on similar occasions hereafter, imitate the noble example of the Eastern managers.

Your devoted reader and subscriber,

BUTANA, N. Y.

J. N. FERRIER.

The Syracuse House.

To the Editors of the New Geneva Farmer:

SIRS—I have just discovered in the last number of your valuable paper, an article headed "Accommodation at Syracuse—a man charged a dollar a meal," and signed by "A Member."

In one paragraph in this article, the author states "we found ourselves very modestly charged at the rate of about one dollar a meal, including breakfast and supper, throughout."

Who the author of this article is, or what was his object in making the above statement, I am at a loss to determine. The house referred to, where this exorbitant charge was made, is evidently the Syracuse House, which is kept by me. Aware that there was some mistake with regard to this matter, I have, since the above article came under my notice, made special enquiries of my book-keeper, who receives all bills at my house, and by him I am assured that no single instance of the kind above stated, occurred during the Fair.

To such persons as only came to dine, a dollar was charged for the dinner. But when gentlemen had put up at the house, and in all other cases, no more than the usual charge was made; and in no instance whatever, was a dollar charged for breakfast or supper, as stated by your correspondent.

In those cases when a dollar was charged for a dinner, it was not for the purpose of excluding any one, or, in the language of your correspondent, "to secure select company," but because the occasion being an extra one, an extra outlay was required to provide for it.

That no unjust imputation may rest upon me, you will do me the favor to publish this statement, and assure your correspondent that if he or any other individual will produce an instance during the Fair where charges were made in my house other than as above stated, I will refund double the amount of any such bills.

Very respectfully yours,

P. N. RUST.

Syracuse, Nov. 23, 1841.

Remarks, by the late Editors.—In relation to the "object" of "A Member" in writing the communication referred to, and especially our object in publishing it, we can assure Mr. Rust it was not to gratify any feelings of ill-will towards him, or a desire to injure his house; but observing at the time that much dissension prevailed on account of the charges, and that some blame was attached to the managers of the Society, we were desirous that such notice should be taken of the matter as would tend to prevent like cause of dissension hereafter. We sent Mr. Rust's letter to "A MEMBER," and he returned it to us with the following remarks enjoined:—

"I can only say in reply to this communication, that I was charged at the rate of about one dollar a meal—that is, throwing out one or two things, which I do not know were reckoned or not, the bill would amount to what I have said; and I was told by others that they were charged similarly. Whether the man

who made the charge was the regular book-keeper or not, I cannot say. Your correspondent says, 'when gentlemen put up at the house, and in all other cases, (than dinner) no more than the usual charge was made.' The usual charge where? At the Syracuse, or at other houses? Is the usual charge at the former, for breakfast or supper, seventy-five cents? Again, a dollar was charged for dinner, to cause 'the occasion being an extra one, an extra outlay was required.' By this rule, the merchant must be higher when his custom is large—the farmer who feeds a hundred head of cattle, must charge more per head, than he who feeds but one—and division of labor becomes a loss instead of an advantage. I thought tavern keepers always practiced a good custom, to a scant one, and could make more money at given prices with a hundred boarders than with three."

For the New Geneva Farmer,

Valuable Pear Trees.

"I don't want any pear profits set," exclaimed the old gentleman, "I shall never live to see them bear." In the early statement of this place, although we had a few apple nurseries, but these mostly of natural fruit, yet a choice pear, plum or cherry tree was not to be had. About this time, (30 years ago) one of those itinerant grafting men, so common of late years, came along engraving for all who would employ him; and although, unlike some at the present day, he did not profess to have any of the most choice varieties of fruit known, yet it cannot be denied but he had some good kinds of apples and pears. He was employed by my father to set some apple grafts, and when his job was nearly completed, he asked my father whether he would have a few pears grafted. "No," replied the old gentleman, "I don't want any, I shall never live to see them bear." On being again urged to have a few set, he replied, "Well, I don't care, perhaps some of my children may live to see them bear." Accordingly, a few were set on the stocks of the wild thorn, cut down below the surface of the ground. Three of these survived and are now large trees.

And here let me stop to enquire whether the investment has been a profitable one. They cost when set, say 25 cents, and these three trees are now worth at least three hundred dollars. One hundred dollars may be thought a great price for a pear tree, but we must value fruit trees as we do other property, according to the net profits derived. A pear tree 30 years old from the graft, may be supposed to hardly have reached its prime, probably will continue in full vigor and increase in value for 20 or 50 years to come. Probably the most valuable pear trees in the western country, are now growing near Detroit, and are supposed to be upwards of an hundred years old.

But to return to my story; two of the three pear trees were owned by my father at the time of his decease, which happened near four years ago; and although at the time they were engrafted, he was quite sure he never should live to see them bear, yet he enjoyed the fruits of them for many years. One of these trees, called the Autumn pear the year before his decease, produced twenty three bushels of pears; the other, called the Orange pear, produced about half as many. Since then, the Autumn pear has produced as high as thirty-five bushels in a year; and they are never worth less than one dollar per bushel. The other two trees are of the Orange pear, and although much exposed to the depredations of certain two legged animals which it is quite impossible to fence against, and although only producing about half the quantity of fruit as the former, yet the fruit is of a superior quality, and often sells for two dollars per bushel.

Now I ask, are these trees worth \$300? Where can we find an investment of \$300 that produces a greater income? A year or two previous to the old gentleman's death, on seeing his trees loaded with

fruit, I called his attention to the history of these trees; and when I repeated the expression that heads this article, he replied, "Ah, if instead of three or four I had then had one hundred, they would now be worth a fortune; yes, a fortune—worth more than the best farm in this country."

A writer in the Farmer asserts that a choice pear, cherry or plum tree cannot be found on one farm in four in Western New York, and which, for aught I know, may be true; yet for the last few years I have had ample demonstration that shows most conclusively, that an increased attention has been given to procuring choice varieties of fruits. And even as regards the pear tree, the expression that heads this article, is now rarely made.

Buffalo Nurseries, Dec. 21, 1841.

For the New Geneva Farmer.

Agricultural Meetings.

Our annual agricultural exhibitions are profitable and interesting; but they have a direct influence upon but a small portion of the community. It has often occurred to me that meetings of a more local character, in which farmers could convene and relate their experience, discuss specified subjects, and compare their views generally, would be attended with happy results. If circumstances would permit, could the intelligent Editor (who will be most cordially welcomed in Western New York) better subserve the interests of the cause in which he is engaged, than by making a series of appointments in such towns as he may think proper, and thus set this ball in motion?

W. R. SMITH.

Macedon, 12mo 23d, 1841.

White Carrots.

Are every way worthy of culture, yield much better than the Orange, and on light soil, are as easily gathered as turnips, and then such winter butter as the cows make when fed on them! Just call in some long evening, friend Editor, and examine for thyself.

Straw.

How can I make my cattle eat straw? I have often asked of some experienced farmers. "Give them less hay," was the general reply. Not liking this mode however, and knowing that good farmers in England and this country made free use of straw as food for cattle, I resolved last summer, when threshing, to change my plan. I stacked it as usual, but in the progress of the work, sprinkled on from one to two bushels of salt. I used the "Fitts Thresher," which gave me the additional advantage of mixing the chaff through the whole. Well, during the warm weather in the first part of this month, my cattle, instead of wandering about with but little appetite, might be seen any day eagerly engaged in filling themselves with straw. At night, when the cows were tied up to receive their rods, their hay would be almost untouched. Their rotund appearance left me no apprehension of their starving, however. This was continued until nearly the present time, when I was obliged to reserve the remainder of the stack for the use of the stables. Nearly a month's feeding of hay was saved.

W. R. S.

Root Culture.

Among the premiums awarded at the Agricultural Fairs in the State of New-York, we notice the following valuable products:—Mangel Wurzel, 1600 bushels; Sugar beet, 1160 bushels; Ruta Beca 1200 bushels; Carrots 720 bushels; Potatoes 400 bushels. These products, considering the dryness of the season, are remarkably good, and go to prove the truth of what we have often maintained—the great advantage which would result to the agriculturist, were he to devote a few acres to the culture of roots for winter provender for his stock. The degree of comfort such a course would secure to the animals generally, and the profit arising from the increased quantity of butter and milk which would be yielded by the milk cows, are considerations which none who are regardless to their interests, will, we are sure, overlook.—Am Farmer.

ROCHESTER, JANUARY, 1842.

To Readers and Correspondents.

The non-arrival of Mr. Colman must serve as an apology for any deficiencies that may appear in this number. Our readers may rest assured that full amends will be made hereafter.

Our acknowledgements are due for the good number of valuable communications received during the past month. Some of them requiring Mr. Colman's supervision are necessarily deferred till our next. *Agriculture* is welcome to our columns; we hope to hear from him (and others of our friends) often. Quite a number of inquiries, notices of periodicals, &c., are awaiting editorial attention, and for the delay of which we claim indulgence.

Mr. Colman intends leaving Boston in time to attend the meeting of the State Agricultural Society at Albany on the 18th and 19th inst., and then coming to Rochester.

Cream Pot Breed of Cattle.

Samuel Jaques, of Charlestown, Mass., at his Stock Farm near Boston, proposes to offer on the 10th of January instant, at public sale, a large number of Cows and Bulls of his improved stock. These animals have been bred with great care. They are descended from an Improved Durham Short Horn Bull and one of the best cows ever owned in Massachusetts. This cow was most remarkable for the peculiar richness of her milk, and its large proportions of butter properties. Mr. Jaques assures the public that the progeny partake of the qualities of their ancestry. They are generally of a deep red color and more than medium size, and are without doubt, among the best cattle to be found in New England. The sale will offer a favorite opportunity for persons who wish to improve the character of their milking stock. This attempt of Mr. Jaques is probably the first systematic attempt made in the country to form a superior dairy stock. Several of his animals are of the fifth generation.

Gate Hinges and Gate Fastenings.

Most of our readers may have seen an estimate of the relative cost in using bars and gates for one year, and the consequent economy of the latter. It may be easily conceived, by thinking of the labor required to open and shut a set of bars five hundred times in immediate succession, and then the same for a gate. A very good thing was mentioned in a late number of the Cultivator, of R. W. Scott, a farmer of Kentucky, every field of whose farm was entered by a well-hung, self-shutting, and self-fastening gate, and each field numbered conspicuously on the gate-post.

Many gates are passed twenty times a day, or more than seven thousand times a year, and it is a matter of some importance whether they shut easily or not.—half a minute spent in dragging a half hung frame over the ground, and crowding a pin with difficulty into a snug hole to fasten it, amounts, in such a case, in one year, to no less than one full week of hard labor.

HINGES.—As a corrective to the falling of gates from their original position, the following is a good, but not new mode, though but little known and used. Fig. 1, represents the part of the gate attached to the post, and the hinges; the eye *b* of the lower hinge has a screw cut upon it, and by means of the nut *a*, the

gate head may be elevated or depressed at pleasure.—This is often very convenient when the gateway is obstructed by snow.

In order that a gate may be self shutting, it should be hung as follows:—Having set the post upright, draw a plumb line on the face of the post, and by this line set the hook of the upper hinge; and the hook of the lower one two inches from this line, on the side to which the gate opens; this will cause it to fall shut, while opened less than ninety degrees or the quarter of a circle. To continue this tendency to fall, when opened still wider, let the upper hook project four inches from the post, and the upper eye or loop two inches from the gate; the lower hook project two inches, and the lower eye four inches. A gate thus hung will fall shut through the half circle.

FASTENINGS.—These are almost as various as the mechanics who make them; and are of all grades, from the leather strap tied round gate and post, to the well made spring—latch shutting with all the precision of a mortise lock on the house door.

An excellent latch for a farm gate, in frequent use, is the horizontal wooden bar or bolt, suspended either at the middle or at each end, by a short chain and staples, and sliding through a mortise in the gate-head, into a corresponding mortise in the post. When drawn back in opening, the chains being thrown from the perpendicular, the weight of the bolt throws it back to its place. Fig. 2, represents this fastening; *a*, the bolt; *b*, the chain. The dotted lines show the place of the chain and bolt when the latter is drawn back.

The fastening represented by Fig. 3, has been found, by the writer, simple, cheap, and effective.—*a* is a rod of iron, half an inch or more in diameter,

bent as shown, passing through the two narrow mortises *c c* in the head of the gate, and moving on a pin at *b*. When the gate is thrown shut, this iron latch strikes the projection *d* on the post, and is lifted backwards; its weight causing it to drop forwards as soon as the gate is shut. Such an iron rod, for a large farm gate, need cost but a shilling or two, and any farmer of ordinary skill may bend it to suit his fancy, by beating it in a stove, with a few minutes work. It may be made much shorter than represented, if desired.—Besides being cheap, and never liable to get out of order, a little sinking of the gate, not affecting it, it is easily opened by persons on horseback. J. J. T.

For the New Genesee Farmer.

Steuben Co. Agricultural Society.

MR. EDITOR—I send you a notice of the first annual Meeting and Fair of the Steuben County Agricultural Society; also a notice of the last meeting of the Society's Board. It is not yet a year since the question was raised in good earnest by a few enterprising citizens of this county, whether they should have such a society or not. This circumstance, together with the fact that the great mass of the farming community felt but little or no interest in the subject, put it out of the power of the Society to say what, or how large premiums should be awarded at its late fair. But feeling that such an exhibition as, by the blessing of God, they might be able to make, was the best, if not the only means in their power to awaken interest in behalf of their cause, the Board appointed Wednesday, the 10th of November last, as a day for the election of new officers, and for exhibiting such animals and articles of domestic manufactures as those who were already enlisted, or who would then enlist in the cause, might see fit to make.

The wisdom of this step has since fully appeared. The day was highly propitious, and at an early hour it was seen that the most sanguine had failed to imagine the deep interest that was everywhere being manifested in the operations of the day. Our list of names was swelled to one hundred and eighty-three; and the cattle, horses, sheep, hogs, &c., that were presented would have reflected honor upon a society of *more* days.

The following is a list of the officers that were chosen for the present year:

Lazarus Hammond, President. Otto F. Marshall, Israel R. Wood, Lyman Balcom, Vice Presidents. Zibact Leland, Corresponding Secretary; Theron Loomis, Recording Secretary; Henry Brother, Treasurer.

EXECUTIVE COMMITTEE.

Henry Wambaugh, Lay Noble, Elias Mason, Samuel Cook, Warner Patchen, John McBurney, Sherman Rose, Jacob Van Valkenburgh, Orlando Comstock, William Dixon, William Kernon, Arthur H. Erwin, Amos Lewis, Albert C. Morgan, Stephen Kent, Nathaniel Mallory, Levi Davis, Harvey Andrews, Samuel Mathiolen, Otis Thatcher, Daniel N. Bennett, Joel Canington, Johnson Reynolds, Wm. Hastings, Hiram Merriman, Jason Chamberlin, Amasa Stanton.

I send you a paper containing a list of the premiums awarded at our recent Fair.

(Received but have not room to publish.—Eds.)
T. LOOMIS, Rec. Sec'y.
Bath, Steuben Co., N. Y. Dec. 25, 1841.

"The Chautauqua Co. Silk Journal."—We have received the first number of a paper with this title, published at Dexterville, N. Y. by Edwin P. Lord. Mr. L. is said to have been many years engaged in the Silk business, and he appears to understand it thoroughly. He gives some interesting statistics of the extent and success of the Silk Culture in Chautauqua and some other counties; and if his paper is supported as it deserves to be, it will tend greatly to encourage this important cause.

NEW HORIZONTAL WINDMILL.

The use of wind power for propelling machinery, is a subject of considerable importance to the Agricultural community, although it is one that has received very little attention. Indeed we have often wondered that more use is not made of this cheap and powerful agency in this labor saving country. In those parts where water power is scarce, wind power can be made a good substitute for driving ordinary Mills and other Machinery; but in addition to this we believe it might be used to great advantage on many of our large farms for such purposes as cutting fodder, grinding corn on the cob, sawing wood, pumping water, &c. &c. The principal objection to using *Old Boreas* we apprehend is, not that he is unable or unwilling to work, but the difficulty of *harnessing* him so that he can be easily managed: we wish therefore to suggest to our readers a plan for removing these objections. The above cuts (form) led us by the N. Y. Mechanic represent a very beautiful and ingenious contrivance, of which it is said "all the difficulties heretofore existing in the Wind Wheel, have been overcome. The inventor not only claims this as an improvement on all others, but that it is the "ne plus ultra" in Wind Wheels. The advantages are as follows: Firstly, every sail is at all times geometrically correct as to its position to the wind to exert the greatest force in propelling the Wheel; its power is double that of any other Horizontal Wheel. Secondly, the sails are so constructed, that they open at a given pressure, and "flow" the excess of wind to pass through. Thirdly, it can be stopped instantaneously, and as quickly be again set in motion; in the same wind it will move with different degrees of power: for instance, if you have wind sufficient to run four run of stones, and your Mill is set to that power, you can instantly reduce the power of the Wheel to drive two run of stones with the same speed that it drove the four run with.

EXPLANATION.—A, is a plan of the Wheel; B, an elevation in perspective; C, the vane, supported by a pitman, and connecting rods, are attached to the crank; E, represents a section of the mill, showing the manner in which the slats open when the pressure of the wind is greater than required.

For further information and particular description, or for the purchase of Rights, inquire of the subscriber, at 203 Delancey, or 31 Ann street, New York, (if by letter, post paid.) JOHN M. VANOSDEL.

New York, December, 1841.

News from England.

The Steam ship *Columbia* brought London dates to the 3 Dec. and Liverpool to the 4th. The news is not very important. Trade was very dull and Money in great demand. The prices of flour and grain had declined.

The Banker's Circular announces that a strong conviction prevails that "the present government will recommend to parliament a material alteration in the existing corn laws."

It appears by the late advices from England, that poverty and distress, to an extent which can hardly be conceived of in this country, continue to exist among the lower classes in the populous towns, and many are actually starving in the streets—others are induced to commit crimes in order to relieve the sufferings of their families.—The following is an extract, presenting an appalling picture, from a late English Journal:

"On every hand we hear of the abounding of disease; and not only so, but of its rapid and alarming increase. It is not one particular branch of industry that is assailed—it is not the trade of one particular country—but all seem liable to be involved in the widening and destructive circle. Tales of woe and suffering, that are almost too horrid for belief, are repeated

from the West Riding of Yorkshire, whilst Lancashire awakens echo with the painful response. From Paisley to Spitalfields, a cry of all but absolute famine prevails."

Again we are told that the debtors' prison in Newcastle, Durham, Lancaster, &c., are all crowded to excess, from the commercial failures which have taken place within the last year. Another London journal tells us that on the 28th ult., there were 714 persons confined for debt, in the five metropolitan prisons!

How long will this state of things continue? The wealthy landed proprietors, and the lords of the princely halls and the immense estates, will not part with their worldly inheritance, to relieve the poor and humble operatives, who are willing to work for a mere pittance, but even that privilege is denied them. The only remedy left appears to be emigration, and shiploads of poor Englishmen are every week sent to Australia or the provinces in North America—and many find their way to the United States.

MARL IN VERMONT.—It is said that a bed of shell Marl has recently been discovered in West Albany, covering a tract of at least fifty acres, and it appears to be nearly inexhaustible.

He is gently learned who has learned how little he knows.

NEW-YORK MARKET, Dec. 22.

FLOUR AND MEAL.—Since the arrival of the last steamer there has been no demand for export, and very little for home use; and as there is a disposition on the part of some holders to press sales, prices are again unsettled and we reduce our quotations fully 12 cents per bush. We quote Genesee and Ohio \$5 a \$6 1/2; and Troy and Michigan \$6; the latter is scarce.

CATTLE MARKET.—At market 600 head of Beef Cattle, including 60 left over last week, 200 of which was from the South and the balance from this State; 35 Milch Cows and 2000 Sheep and Lambs.

There was some further improvement in good Beef, but the common and inferior qualities are without change.—Sales of 750 head at \$5 to \$7 1/2, averaging \$5 the 100 lb.

MILCH COWS.—25 were taken at \$25 to \$35 each. SHEEP AND LAMBS were mostly taken—Sheep at \$150 to \$140; Lambs at \$1 25 to \$3 each.

HAY.—The market has been well supplied, and sales have ranged from \$7 1/2 cents to \$1 1/2 the 100 lb.

CINCINNATI PORK MARKET.

The Cincinnati Gazette of the 22d December states that the business of Pork-packing at that place is going on very briskly; "that the slaughter-houses are in their glory;" "that the slaughtering is on so large a scale that Deer Creek runs with blood, and the purple current is to be found in the water of the Ohio flowing by itself a mile and more from the slaughter-house!" About 4000 head per day were brought in during the week previous, and the prices were rather on the rise, \$7 25 and \$2 40 being paid for best qualities.

Swelled Fruit Buds—Peach Trees—How to Read.

[I have of a letter from Cuyler Co. N. Y.]
At page 161 of your last volume, it is mentioned that *Juliane* pear tree had, in its leaves during the drought (as it would have done in Autumn) but revived by subsequent rains, it had taken a new start (in spring), and that one bunch had come into full flower. From the same cause, the fruit buds of the cherry, apricot and peach are much swelled in this quarter; and those of the last especially, are so far advanced that a few days of mild weather would be sufficient to expand them.

Whether they can survive until spring, or not, must depend on the temperature of the winter; but unless it should be unusually mild, I shall entertain no hopes of a crop next season. The exact degree indeed, at which swelled buds perish in winter is not known; neither do I know whether cherry buds in the same condition, are harder than those of the peach; but from some recollections in regard to the latter, I believe they are generally safe here, when the cold is above zero.

Some writers ascribe the decay of the peach tree to *budding*; and pretend that seedling trees are more healthy. I have never seen any thing to corroborate the notion. I have trees now in my fruit garden that were budded twenty years ago, and they are as healthy as any seedlings in the country.

On the same day that Congress met at Washington, the crowds held a convention in the woods near this place; and judging from the thousands that attended, I should rather think it a "mass meeting" than an assemblage of delegates. I remember several similar gatherings, which have generally been in the fall, but not continuing more than a day or two. I am not aware that any ornithologist has noticed this circumstance.

On the present occasion they seemed to be in earnest debate, though not more disorderly than some of their better under particular excitement. If they had a speaker, his voice and authority must have been unavailing, for their clamor rose at times, on the wall, like the roar of Niagara.

Having neither pay nor rations however, a protracted session was out of the question, so the adjournment was carried by acclamation, and the duck club passed away. Whether the old resident crows of the neighborhood were engaged in the enterprise, is not known; but they were seen soon after, flying over on their daily excursions, as if, like Gallo of old, they cared for none of those things.

A few days ago, when the ground was bare and well soaked with the late rains, overseers of highways or canal hater for that off, especially if they have the bump of observation, might have been profitably employed for a time, in examining the condition of the Poplar Ridge road—the direct stage route between Auburn and Ithaca. Wherever the ground was nearly in its natural state—that is, had not been disturbed by the plough, the horses could proceed on a trot; but on the contrary, wherever the road had been raised by the scraper, the rutted and the mud was so deep, that the traveler was glad when he got safely through. The contrast was very remarkable.

Now what was the cause of this difference?
Some years ago, I heard one of our Judges, in his testimony before a board of inquiry, say that six years at least were required for a new road to become fully settled on a firm, like one that had long been traveled. This opinion, as the result of observation, had no reference to new roads through the woods; but such as are built up by the scraper, when suds, and muck, and chips and whatever else is at hand, are carried

over promiscuously, and without discrimination or selection into a pile.

Six years for a road to become settled? Why, if this is true, what are our paths now this every year about when they spend the strength of the drought in making *long dry beds of mud* for the earth for us to travel over.

But can it be true that six years are required for a new embankment to settle? If it were made of sound stuff—a clean subsoil mixed with sand and gravel, it would not be long for it would soon become compact; but when it is made of such materials as corn and potatoes delight to grow in, it is true to the letter. The fifth with much of the fine earth has to be washed away by the rains; and not only that which is on the surface at once, but all that which the wading horse and loaded wheels bring up to the surface at another time. All such impurities in the swept away before the road can become firm and good, not sinking under the hoofs of the horse nor the wheels of the carriage.

Now all this interesting correspondence exactly with the condition of the Poplar Ridge road, and with that of every other road in the winter which is much traveled. For many years, I have observed that the best roads are generally those which are the most neglected. Except in regard to bridges, dug ways, and hitching to men of the water, the lowest path-maker is commonly the best, because it is better to do nothing than to do much.

When the State of New York shall waken up in regard to roads, she will manage things differently. She will not allow her expenses to be heavily taxed so needlessly. Skilled superintendents will be paid for their services, and our taxes will be judiciously applied. Thousands are annually wasted through false economy. If her *cash* policy were no better than her *road* system, instead of a revenue of two millions, she would have a line of duck ponds.

The admonition of the prophet, would apply well to our overseers of highways. "*Case to do evil. Learn to do a ill.*" Quit plunging up the sides of the roads, and destroying your sleigh tracks. Use your *scraper-hog* to cut down banks and ridges—*not* *crusts* to haul in suds, muck, and mud. GRAVEL YOUR ROADS; and if the material is not within one mile, go two. Every road is a road look for the present time, for the present age, and for posterity.

Temperance Reform—Home League.
It strikes us that the present is an era of great reforms; great abuses in social life having reached the ultimate point of human endurance, a retrograde movement as the unavoidable consequence has commenced, which promises under a kind providence, to bring back the moral and social health of the nation.

The great ten, temperance reform is the first in order; when the benevolent and God-like of the land commenced their labor in the cause, they despaired of doing any thing more than to make the practice of drinking odious and unfashionable, in order to arrest the young N. b. boy of our presence in his downward course of fashionable delusion. The port-wine drunkard was given up as a pastal power of reform, his habits were considered too chronic to be within the reach of human aid! What is the consequence of this neglect of this unfortunate portion of God's accountable creatures? Verily the words of scripture that the "last shall be first, and the first shall be last," is now in the rapid progress of fulfillment. Who are now the miracle working missionaries in the temperance cause, 'tis true they do not raise the dead, but they perform these miracles which are the "next of kin;" they draw from the kennel of dark the long lost abandoned set, quickening him by the force of sympathy and kindness into a thing of life, and

health, and usefulness! Every distillery is now shut up! The drug shop is now converted from a charnel house of corruption, into the busy mart of life and comfort! The more respectable tavern, now finds its bar-room a boundless appendage, while those of lesser note sink to ruin.

"And make no sign."
The next reform in order is the Home League. Who that has seen blood in his veins, does not feel a thrill of domestic comfort at the very sound of such a name. But alas, it strikes us that its office is not properly understood by those who proclaim its duties. Unlike the temperance reformers, they call upon Government to aid them by prohibitions and restrictions, to arrest that over-trading in foreign finery, which can only be effectually done by a labor of love and the power of domestic example. Blessed would be that home league; verily it would compass more than twenty tails, if it could by the power of its action in the home circle countervail a part of those evils which grow out of the equality of our institutions; I mean the general epidemic for expensive foreign finery, the grinding waste of that ever changing fashion, and unlimited extravagance, which provides all grades of society in our land; that morbid appetite for external show among our men and women, which resists with demonic force, alike the precepts of morality, the restraints of insolvency, and the more dark and tangible barrier of grim poverty itself.

It is said that in England among the genteel classes of community, economy in dress and living is made a matter of boast, while the family that should indulge in fashionable show beyond its pecuniary ability, is held up to universal ridicule. For be it from us to wish to impose restraint upon society in these United States, inconsistent with our foreign trade, or our great national progress in refined civilization. But we can see no more danger to these interests in thus curtailing the excessive importation of foreign fabrics, than is now produced by the temperance reform in the diminution of our imports of wine and brandy.

In the beginning Jesus taught of the beauty of simplicity, and in his perfect life he gave example of its truth. St. Paul preached it and his epistles enjoin it with eloquent and earnest allusion; the early Christians followed the precepts and example of their master, some of them it is true, in over zeal, carried the point a little too far; 'tis said that Chrysostom rebuked the "eaters grey," for the too nice fitting of their simple attire. At the court of Louis 14th, the Arch bishop denounced from the altar, the meretricious taste of the females of the court. But in our republican land in these last days of light and protestant reform, fashion and extravagance is ten fold more universally than in any other part of the civilized Christian world. It is a gangrene on our social system, which promises, if not restrained, to uproot morality, and bring all our boasted professions of religion to shame.

We have read of savages so addicted to gambling that when they had lost all, they set up their own children! We have not done this great sin; but we have sold our *littlings* for dust! our *State Stock* are pledged for the payment of debts based on foreign finery, and children yet unborn must redeem them!

Waterloo, Dec. 15, 1841. S. W.

Mr. Editor.—The following memoranda contain so much good sense, given in a plain, familiar manner that I believe you will think them worthy of a place in your columns. They are extracts from letters of a practical man to a novice in the business of farming yet may perhaps give instruction to some "old hand at the plough."

Sheep.
I consider them the most pleasant as well as profitable branch of farming—indeed there is no doubt

it. The experiments I made were under disadvantageous circumstances, convinced me perfectly. I think I have heard you say there are some on the farm now, look well to them this winter, and you will be convinced of the justice of my remarks before many months. You will find that your flock is doubled (with proper care and attention) every year—that the manure will pay all the trouble and what it takes in the way of fodder to support them. In the summer they will live where nothing else can, and improve, or rather give barren fields more than they take off, and the wool, in consequence, will be clear profit—thus:—

100 sheep cost, say \$3 per head,	\$300
100 lambs worth to you \$3 per head,	300
3 pounds wool each, 300 lbs. at 35c,	105
	DR.
	\$300
	CR.

One of the principal maxims as regards these, as well as cattle, is to have them well attended to in winter. Economy, to say nothing of humanity, requires it—it is neglected at this time they get out of condition, and it will take half the summer to restore them to good order, and all the time they are recovering, they are not profitable—hence the economy—for just so much time is lost. The best plan to winter cattle, is to get them into as good condition as possible in the fall—when it costs comparatively little, for the grass is then the strongest—keep them up in condition during the winter, and they enter spring profitable at once, without loss of time or provender.

Turnips, Ruta Baga and Beets.

You will have to be careful to raise a crop of turnips, for the fly is very severe on them when young. Fine lime dusted over them is a great protection.—For winter use I would not advise you to depend on them, as they do not keep good longer than Christmas; after that they get watery and hollow. Ruta Baga is much better, and are sound and good the whole season. For cattle they are not so much liked as beets, and are not near as profitable. I would advise you, by all means, to pay every attention to the latter—where there were potatoes last year, particularly if it was well manured, is the very ground for them. Have it well prepared—ploughed deep and well, to make it fine—cultivate with the plough, keep the weeds out, and you will be astonished at the result. These, cabbage, ruta baga, and indeed almost every vegetable can be cultivated with the plough, not only as well, but better than with the hoe, and at a great saving of expense.

Manuring Gardens.

If your garden has been manured regularly with stable manure, as I suppose it has, you will find a great advantage in trying lime and ashes—the latter from the ley tub are very good—and all the stable manure you will want in the fall for the garden, should now (April) be hauled into a dung pile; you will find it when wanted, rich and mellow.

Farming Generally.

The grand secret in farming, I am well satisfied, is to be early in planting and having your ground in good order—well ploughed and harrowed.

Get your oats in as soon as the ground is fit for ploughing—be sure to roll them when about two or three inches high, and do it well, just before a shower if possible.

Finish planting your corn one day before any of your neighbors, and if your lands or help are wet by rain in covering the last hill, so much the better. Keep working at it until it is above knee high, and you will have no further trouble, except, perhaps, to enlarge your crib.

IMPORTANT DISCOVERY.

MESSRS. EDITORS:—Some time since, you published an article from a French paper, on the subject or process of self-manuring land, for growing wheat. En-

closed, you have another article from the same source on the self-manuring process for the Grape. This experiment too has been tried, with complete success, on the continent of Europe. They are spoken of not as experiments, but as practical results. And if there is any reliance to be placed on them, they are invaluable, and well worth the attention of all, especially so, to our agriculturists. You will confer a favor on the writer, and no doubt on all your readers, by giving the enclosed as wide a circulation as possible. And let all who have an opportunity use themselves of an experiment so cheap, and if found successful, so beneficial, that is to produce an entire revolution in agriculture throughout the world. Nature speaks volumes for it, and the ease and happiness of the human race, invite all who have an opportunity, to test it. W.

Discoveries in Agriculture.

A few months since we extracted from a Paris paper, the *Revue*, a statement to the effect that the straw of wheat, scattered over a field in which wheat is sown, makes the best manure that can be procured. The same paper furnishes us with what it considers a parallel case, in the mode adopted by certain vine dressers of France, who cut off the leaves and twigs of the vine, and mingle them with the earth about its roots; and in that way it is said, produce the most hardy prolix vines that are known. He quotes from the "Organic Chemistry" of Doct. Liebig, one of the most distinguished philosophers of Europe, the following remarks in relation to the subject:

The observations contained in the following pages should be extensively known, because they furnish a remarkable proof of the principles which have been stated in the preceding part of the work, both as to the manner in which manure acts, and on the origin of the carbon and nitrogen of plants.

They prove that a vineyard may be retained in fertility without the application of animal manure, when the leaves and branches pruned from the vines are cut into small pieces and used as a manure.

According to the first of the following statements, both of which merit complete confidence, the perfect fruitfulness of a vineyard has been maintained in this manner for eight years, and according to the latter statement, for ten years.

Now, during this long period, no carbon was conveyed to the soil, for that contained in the pruned branches was the produce of the plant itself, so that the vines were placed exactly in the same condition as in a forest which receive no manure. Under ordinary circumstances, a manure containing potash must be used, otherwise the fertility of the soil will decrease. This is done in all wine countries; so that alkalies to a very considerable amount must be extracted from the soil.

When, however, the method of manuring, now to be described is adopted, the quantity of alkalies exported in the wine does not exceed that which the progressive disintegration of the soil every year renders capable of being absorbed by the plants.

[The author then proceeds to scientific calculations, which will not interest the general reader. After these we have the two cases alluded to, taken from an article by M. Krebs, of Soeheim, in a German periodical of July, 1840:—]

In reference to an article in your paper, No. 7, 1835, and No. 29, 1839, I cannot omit the opportunity of again calling the public attention to the fact, that nothing more is necessary for the manure of a vineyard, than the branches which are cut from the vines themselves.

"My vineyard has been manured in this way for eight years, without receiving any other kind of manure, and yet more beautiful and richly laden vines could scarcely be pointed out. I formerly followed the method usually practised in this district, and was obliged in consequence to purchase manure to a large amount. This is now entirely saved, and my land is in excellent condition.

"When I see the fatiguing labor used in the manuring vineyards, horses and men toiling up the mountains with unnecessary materials—I feel inclined to say, all, come to my vineyard and see how a better method has been discovered. I have provided that vines shall manure themselves like trees of the forest, and even better than they! The foliage falls from trees in a forest only when it is withered, and it lies for years before it decays; but the branches are pruned from the vine in the end of July, or the beginning of August, whilst still fresh and moist. If they are then cut into small pieces and mixed with the earth, they undergo putrefaction so completely, that, as I have learned by

experience, at the end of four weeks not the smallest trace of them can be found."

The following remarks are by the editor of the periodical. We find the following notices of the same fact in Henderson's "History of Wines of the Old and New World:—"

"The best manure for vines is the branches pruned from the vines themselves, cut into small pieces, and immediately mixed with the soil.

"These branches were used as manure long since in the Bergstrasse," M. Fournelle then says:

"I remember that twenty years ago, a man called Peter Muller, had a vineyard, in which he manured with the branches pruned from the vines, and continued this practice for thirty years. His way of applying them was to hoe them into the soil, after having cut them into small pieces.

"His vineyard was always in a thriving condition; so much so, indeed, that the peasants here speak of it to this day, wondering that old Muller had so good a vineyard, and yet used no manure."

Lastly, Wilhelm Rul, of Schriesheim, writes:

"For the last ten years I have been unable to place dung on my vineyard, because I am poor and can buy none. But I was very unwilling to allow my vines to decay, as they were my only source of support in my old age; and I often walked very anxiously amongst them without knowing what I should do. At last my necessities became greater, which made me more attentive, so that I remarked that the grass was longer in some spots where the branches of the vine fell, than in those where there were none: so I thought upon the matter, and then said to myself—If these branches can make the grass strong and green, they must also be able to make my plants grow better, and become strong and green." I dug, therefore, my vineyard as deep as I could put dung into it, and cut the branches into pieces, placing them in the holes and covering them with earth. In a year I had the very great satisfaction to see my barren vineyard become quite beautiful. This plan I continued every year, and now my vines grow splendidly, and remain the whole summer green, even in the greatest heat.

"All my neighbors wonder very much how my vineyard is so rich, and that I obtain so many grapes from it, and yet they all know that I have put no dung upon it for ten years."

Here is the experience of thirty years, and yet it is confined only to a few sensible individuals, who have the resolution to imitate upon the wisdom of their ancestors, as nature age innovates upon the wisdom of infancy. The husbandman is not a docile animal; he is of Chinese extraction, and adheres to the "good old beaten track" of carelessness and sloth, in defiance of all the elements and laws of nature. The great founder of Chinese medicine, Shin-nung, lived before the flood, and none of his followers have ever excelled him.

Nobody dare improve on such a venerable system; to cure a man upon another principle would, no doubt, cause wonder among the natives, but they would never think of adopting the new system. The good old ways are established creeds all over the world.

"New Discovery in Agriculture."

Respecting the article which we published under this heading in our Nov. No., we find the following remarks in the N. Y. Tribune.

I observe in the Tribune of the 22d ult., an article from a Paris paper, entitled "An important discovery in Agriculture." It is a discovery in France, the fact is remarkable; as it is, and always has been, a well known fact among our farmers, that the leaves of trees, and perishing vegetables on land constitute the manure which the laws of nature have provided for sustaining fertility. So true is this, that when I was a boy and a young man, before the revolution, (for I was bred a farmer,) it was customary for farmers to let their land lie untilled for one, or more years, for the purpose of being enriched by the growth of grass and weeds. This was the great defect in farming; the cultivators relying wholly on this natural manure, without any rotation of crops. Before the Revolution I never knew an instance, in my native village, of an attempt to fertilize land by green crops or rotation.

At this day, there are districts of land, within my observation, which are, year after year, sowed with rye, without any manure, except the stubble of the former crop. In many places, this stubble is sufficient to keep the land in good heart for rye, for any period at pleasure.

The experiments, stated in the article above named, are not in exact accordance with the practice of our

farmers, but all dependant on the same principle.

I have never seen an experiment made by placing grain under straw upon glass; but it is not an uncommo practice for farmers to spread straw upon grass-land for manure.

Whether straw upon the surface will produce more effect than when covered with earth, is a practical question; but I see farmers covering the seed of potatoes with straw, and plowing it in with a shallow furrow-slice.

N. WEBSTER.
[*Ur*] We too were "ired in the Country," and have some knowledge of farming. We were rather favorably struck with the "discovery in agriculture," to which our learned correspondent alludes, and are also inclined somewhat to his opinion that the principle is not *entirely new*. We think we can give a stronger instance of its practical utility than either the French writer or our correspondent, but we only vouch for its truth so far as having heard it when a boy from the lips of a respectable farmer who resided on the banks of the Susquehanna. The statement was this: A portion of his farm was *bare* *clack*, which, in view of the small amount of labor bestowed upon it, he made the most productive. In the spring of the year he had down or planted his potatoes on the rock, and covering them over with straw, paid no more attention to them until fall, when he merely raked off the dry straw and exposed a most abundant crop of the finest quality! The advantages of this method of raising potatoes are:

1. No ploughing.
2. No hoeing.
3. No digging—the rake only being required.
4. They are perfectly dry.
5. They are perfectly clean.—ED. THURNEY.

A Good Thing for Farmers.

There is no one thing, it is believed, that would increase the profits of farming more, and better enable farmers to know what they are about, than the most rigid accuracy in experiments. Here is the great defect in agriculture in Western New York, and doubtless elsewhere too—guessing and estimating, but not actually measuring.

For instance, a farmer believes he has found a very much improved mode of fattening cattle—he feels them so and so—and with this and that; but how does he know how much better his way is than other peoples; and how can he satisfy others that his mode is best, and induce them to adopt it?

How can he? Why let him forthwith procure a weighing machine, such as we use for weighing hay—costing fifty dollars perhaps—a large sum for most farmers; and let him perform all his experiments, by measuring his feed, and at the end of every week accurately weighing each of his cattle, and observing what kind and mode of feeding increases their weight most rapidly. From such experiments, he will soon be enabled to calculate his profit and loss to a dollar. Let him pursue the same course with his hogs, and other animals, at the same time that he endeavors, by reading and inquiry, to learn the best on the subject, and before many years he will have a fund of facts, (and of money too, I trust) of more value, three fold, than the cost of his scales. Who will be the first to do this? Who? [I give you a reply.]

Again—there are many new, and very valuable things, lately discovered in raising crops. It has been found by fair experiment, for instance, that *hwe* on land greatly benefits it—that *much* *much* is of great value for some crops—that *subsoil* *ploughing* will double, perhaps the products of the soil—that certain modes of culture without additional cost, or certain varieties of seed with little additional care, will add bushels to every acre. But who knows the precise amount of profit—if after all these are any profit at all, except under favorable circumstances—if the thing is done only by guessing? A merchant or a banker would find it rather dull business, if, instead of keeping every thing square and accurate, he should set about *guessing* his profit and loss! No wonder then, that farmers sometimes feel a little dull and heartless.

Well—how is this difficulty demolished? Why, you have only to get a *tape-line*, costing about one

dollar,—and measure all your fields—and any farmer who has studied arithmetic, and who has no more than 250 acres, can do this in half a day or a day. Then, count your loads of manure—register the quantity of seed, and every particular in sowing it—and measure, not guess at, the crop which comes from the land. All this on a farm of common size, would not cost in additional time, more than ten dollars; and how much think you, would it be worth? As much as ten dollars! How much would it be worth to each farmer of you, who cultivates fifty acres every year, to know, for a certainty, the way in which he could increase the best products of every acre to the amount of one dollar a year?

And how much value would it be to Western New York, in ten years, if every intelligent farmer would now get a *weighing machine*, and a *tape-line*, and keep accurate accounts, and at the same time inform himself through the New Genesee Farmer of all the best modes of fattening animals, and of raising crops, and of the best seeds, and of the best ploughs, and other implements, and should practise *exactly*, systematically, mathematically, upon the information?

J. J. T.

Treasury Report.—a tariff to protection cannot favor a sound currency, and a free trade cannot encourage an increase of manufacturing industry in the worst of times.

In the late report of the Secretary of the Treasury we find an ingenious argument in favor of increased protection to our home manufacturers: we should have been better pleased to see from the same master pen, an apology for that moderate protection which our present tariff for revenue incidentally gives our home industry.

In times like the present when the whole nation is prostrated by that reaction which has succeeded inflation; we cannot but expect from the fathers of the nation, such councils as will tend to turn the people back to retrenchment and reform, industry and economy, instead of encouraging the delusive hope, that an increased tariff on foreign fabrics will bring back high prices and a prosperous trade to the country.

The Secretary says that "nothing is better established by our experience and the experience of other nations, than that the augmentation of duties, does not augment in an equal degree the cost of the article to the consumer; in many cases it appears not to increase that cost at all, very often the price to the consumer is kept down notwithstanding the increased duties." We would ask then how is our manufacture to be protected by an increased duty? But we apprehend that this part of the Secretary's argument applies only to the ultimate consequences of protection; inflation and high prices are the first fruits, and the only ones coveted by the manufacturer; competition, over production, low prices and bankruptcy follow. The high tariff of 1823 ruined half the manufacturers in New England by the competition it induced, and the only argument we now know of in favor of high protection, is that we should create an evil that good may grow out of it. During the palmy days of Bank making, when money became scarce, new Bank Characters were applied for in order to supply the deficiency; but now when a reaction has deranged the currency, we seek to increase the tariff in order to make up for the fluctuating vicious state of the currency, and our consequent losses by bad debts.

Ask an intelligent manufacturer which he had rather have, all the States south and west, sound and punctual customers, or an increase of 50 per cent in the tariff of duty on foreign fabrics, and what will be his answer, "a nimble penny is better than the slow and doubtful shilling." It is

true that we have bought too much from abroad, because we have bought more than we have sold; but if on present tariff will not prevent this, how can we hope a higher one to do it? If the increased duty raises the price in our market, the foreign producer can still compete with us, as the increased prices will offset the increased duty, and when the price falls our manufacturers will be no better off than they are now.

A member of Congress (Mr. Marshall) in advocating protection, says, "our manufacturers must be guarded and fondled in the first days of their childhood," very true, but the over zealous friends of protection would destroy the health of the child, by feeding it strong meat and stimulating drinks, instead of the more simple aliment suited to its tender age. Under the protection which our revenue bill incidentally gives to our various manufactures, they have been continually on the increase. Our cotton goods are now exported in large quantities, which could not be done if they depended on a tariff to protect them. We know of no one branch of industry which suffers from foreign competition at this time, unless it may be Iron; and as Government has for some years back admitted rail-road iron free of duty, it would now be no more than a just retribution to our Iron manufacturers, to establish the duty, as sundry memorialists have petitioned, at the rate charged by the compromise act in the year 1829.

Much is said and written of late, about foreign restriction on our bread-stuffs, still we find that last year England admitted our bread stuffs under the lowest grade of duty to the amount of six millions of dollars; through the Canadas much of our flour and provisions finds a foreign market at a low rate of duty. If England admitted our bread stuffs free at all times, it would only lower the price of her own corn, without materially increasing the demand for ours; we should also have to compete with Europe for the English market, and Russia and Poland can raise grain cheaper than we can, because their labor is cheaper. But if we had the exclusive privilege of supplying England with all the foreign corn she needs, it would in ordinary years be very little; New England alone consumes more of the production of the West in one year, than is exported to all parts of the world in several years; and this market, based on the rapid progress of manufacturing industry, under the healthy protection which is given by the provision of the compromise law, will be found continually increasing, even in times like the present, when a general bankruptcy threatens the more agricultural portions of the country. If the agricultural states had not involved themselves in debt, our manufacturing states would be in a very prosperous condition at this time.

S. W.

W'atolou, Nov. 28, 1811.

Smutty Wheat in Old Genesee.

MR. GENESEE FARMER—

If worthy of a place in your valuable and extensively read paper, and if, in your opinion, beneficial to the farmers of Western New York, I should like you to hand round to them through your columns, these few remarks in relation to that great evil,—Smut in wheat.

Your readers in New England and elsewhere, will probably many of them, on casting their eyes upon the caption of this communication, exclaim with surprise,—What, smutty wheat in old Genesee? That garden of the Empire State! Can it be, that the wealthy, the intelligent, the enterprising, the successful farmers of that favored region allow their princely fields, their excellent soil to produce this detestable fungi? Yes, Mr. Editor, and however it may reflect on our character abroad as wheat growers, the fact cannot be denied, that

to a considerable extent it is but too true. And it seems to me that so one portion of your columns should occasionally speak out against this great evil.

The origin of this disease, I believe, may be dated as far back as the cultivation of the grain itself; and from that day to the present, numberless experiments have been made by agriculturists of the old world, as well as by those of our own country, to ascertain the cause; and yet up to the present time, the conclusions which have been arrived at, are not entirely satisfactory. One of these experiments ascribes it to too much moisture in the soil, or a too humid atmosphere at a particular stage in the growth of the grain. Another was of opinion that it was caused by an insect. Another that it was a fungus, and that the powder which is similar to that of the common puff-ball of our fields, was the infecting agent. Another is of opinion that the minute grains of smut are in fact insects, and that when they come in contact with the sound seed wheat, they adhere to it, and inoculate it in such a manner as to cause it to produce smut. Another opinion, and which is now generally admitted to be a true one, is that it is a small parasitic fungus, which being absorbed by the roots of the seed grain while in a state of germination, and being thence carried by the sap to the young germ, multiplying rapidly and continues to grow in like manner as the sound grain, which at maturity it much resembles.

But let us turn from the cause to the cure, or rather preventive, which is of far more consequence to the farmers, and this is what you should urge upon the notice of your readers, as of paramount importance to them in more ways than one. They need not expend their time nor their money in making experiments. These have already been made in numerous instances, and in every variety of form, by some of the most scientific agriculturists the world has yet seen; and the result is, a most complete and effective remedy, and one which comes within the reach of every farmer, viz:—To soak the seed in strong brine and then stir into it fresh slaked lime until every kernel is coated. In no single instance within my knowledge, has this failed when properly applied; indeed so perfect a cure is it, that in some sections of Western New York, where formerly the wheat crops were greatly injured, if not entirely ruined by smut, a proper application of this remedy, and an annual continuance of it for a series of years, has totally eradicated the evil; so much so that brining and liming is now considered unnecessary.

Great quantities of smut have been harvested in our town the present season, more than for several years previous. Some farmers of my acquaintance have had such an abundant crop of it, that it was with much difficulty the hands could attend the machine during the operation of threshing, so dense and suffocating was the cloud of smut-dust which constantly encircled them. To these farmers, and all others who are troubled with smut in their wheat, I would recommend a thorough application of brine and lime without farther delay.

Castle, Wyoming Co., N. Y.

Progress of Horticulture—Exhibitions, &c.

In the last number of the Farmer, we very briefly noticed the more interesting portions of the Massachusetts Horticultural Society's report; we now extract from the Magazine of Horticulture, the following items of intelligence from the published reports of other similar institutions. We agree fully and with much pleasure in the remark of the Editor of the Magazine, that these reports bear sufficient evidence that a taste for fruit and flowers is becoming general and is attracting public attention.

Essex Co. Natural History Society.—"During the present season, the Horticultural exhibitions at the Society's hall have gone off with great eclat.

The variety of fruits and flowers was not only greater than at prior seasons, but the number of contributors has very much increased. Several new amateurs have entered the field, and are bestowing great attention to the cultivation of flowers, particularly of the dahlia, or to the growth of choice and delicious fruits.

"Ten weekly exhibitions have been held on Wednesday of the respective weeks, and the annual on Tuesday and Wednesday, September 11th and 13th. The hall was also opened on the evening of the 11th of July, for a display of two of those favorite flowers of midnight, silence, and darkness, "the night-blooming cereus," from the green-house of Mr. F. Putnam. About eight hundred species and varieties of plants have been exhibited in flower; one hundred and fifty were natives of our woods and meadows—the others the product of the green-house and of the garden. Of these last, one hundred and twenty were roses, one hundred and twenty dahlias, sixty geraniums, &c. Of two hundred and thirty-three varieties of fruit, one hundred and twenty-two were pears, twenty-eight apples."

American Institute, New York.—At the fair of this Institution last October, the exhibition of fruit, vegetables and flowers, was excellent.

Exhibition of the Burlington (N. Y.) Lyceum.—The labors of this institution to spread a taste for gardening, have not been in vain. The reporter says: "The fruits exhibited were remarkably fine, and the specimens numerous. The vegetables were greatly increased in number and variety, compared with former exhibitions."

The collection of hot-house and green-house plants, pyramids and bouquets of flowers was very creditable.

Louisville (Ky.) and Jefferson Co. Horticultural Society.—The exhibition of this society in September last, being its first, shows that there is a lively spirit of improvement going on in that region. The report enumerates a much greater variety of fruit and flowers than might be expected in that quarter.

Pennsylvania Horticultural Society, (Phil'd.)—In concluding a long and interesting report of the Fall exhibition of this Society, the committee make the following remarks: "The onward march of horticulture in this community was strikingly manifest at the present exhibition; the great improvement in all the departments of that science was evinced in the increased variety of exotic plants, the successful culture of the rarer and finer fruits, and the remarkable progress in the growth of culinary vegetables. Nor was the growing interest which our citizens generally feel in the subject, less apparent or less gratifying on the occasion, for at no former period have the rooms been more thronged with visitors, or more animated by a delighted and refined public."

These items are such as every farmer should peruse with interest, and be stimulated by them to devote that attention to the production of fruit and vegetables particularly, as their importance in domestic and rural economy would plainly suggest. It is not our wish to infringe on the Agricultural character of the Farmer with such notices as will merely interest the scientific Horticulturist, and which would be neither read nor cared for by the great mass of its readers, but we think it the duty of every Agricultural Journal to keep regularly before its readers the progressive course of those branches of Horticulture, to which every well-wisher of his country should wish public attention might be effectually and generally directed. Example is very powerful, and wherever examples

are afforded as of our brethren in various parts of the country uniting their efforts to promote the advancement of Horticulture, to increase in quantity and quality the products of the soil, thereby aiding onward the great cause of human improvement and human happiness, and when those noble efforts are successful, as they generally are if properly directed, we consider that they should at least receive a brief notice in every journal devoted to the interests of the cultivator.

It must be through the influence of Agricultural Journals, that any thing like the general attention of community can be directed to the advantages to be derived from the practice of Horticulture, and they must be the principal channels through which that knowledge must be conveyed so essential to its progress. The circulation of books or periodicals exclusively Horticultural, is exceedingly limited in any part of this country, in the West particularly, nor can they be made to circulate until both taste and skill have been disseminated; to do this, we would repeat, must be the work of Agricultural Periodicals, and it is pleasing to see that some of the leading journals have already expressed their intention of giving the subject the attention it merits, or at least more than heretofore, during the ensuing year. We hope that all will consider the propriety of doing so and do it. P.

Scarlet Fever.

A correspondent says, "The happiest effects have resulted from washing the patient in weak lye which feels a little slippery to the fingers. It is best to begin in time, when the fever or redness first appears; and with a cloth or sponge apply it all over the child every few hours. But if the fever has got up, it should be repeated every five minutes till the heat abates. One of our children was getting better under this treatment; but his nurse observed in the night, he was again very hot, she washed him all over, and in a few minutes every trace of fever had left him. He felt cool, slept comfortably till morning, and has had no return of it since. Even bathing the feet in weak lye has a very soothing effect."

"Bleeding and strong emetics are bad—nauseating doses of ipecac good. If the throat is swollen, apply sweet oil, or a liniment made of this and aqua ammonia, and drink freely of slippery elm, catnip, or sage tea."

"If the swelling is very bad, it is best to eel in the doctor—or blister, and apply a bag of hops dipped in warm vinegar round the neck from ear to ear, the sufferer breathing the fumes of the vinegar. Gargling a strong infusion of Seneca snake root or Cayenne pepper will do for large children or grown persons; and afterwards use vinegar of squills. Give a dose of calomel when the skin begins to peel off; and be very careful for many days after, not to take cold."

"The country is full of resources, and the people full of energy, and the great and permanent remedy for present embarrassments must be sought in industry, economy, the observance of good faith, and the favorable influence of time."—Tyler's Message.

A BOTTLE OF PORT WINE, of New York manufacture, has been found to contain 3 ounces of alcohol, 4 of cider, 1½ of sugar, 2 of alum, 1 of tartaric acid, and 4 of concentrated solution of logwood.

New doctrines never please the old. They like to fancy that the world has been losing wisdom instead of gaining it, since they were young.

Love labor; for if you do not want it for food you may for physic. It is wholesome for the body and mind.

Learning is obtained only by labor; it cannot be bought with money; otherwise the rich would uniformly be intelligent. Learning regards all men as equal, and bestows her treasures on those only who work for them.

Let him who regrets the loss of time make a proper use of that which is to come.

Improvements in feeding Silk Worms.

The following article, which we copy from an Ohio paper at the request of the author, contains some suggestions on the subject of Silk culture, which may be of service to some of our readers; but we cannot conceive what new invention or discovery Mr. Tillingham claims the right to have secured to him by a patent, nor can we commend the spirit which prompts him to make the attempt. If we were engaged in that business, and desired to feed silk worms according to the plan he describes, we fancy we should do so in spite of any patent he may obtain.—The paper from which we copy, contains several certificates signed by persons who have witnessed Mr. T.'s operations, corroborating his statements and testifying of the complete success of his plans. B.

The Silk Business.

We last week visited the Cocoonery and Silk Establishment of Mr. Joseph B. Tillingham, in this village, and were politely conducted through the different apartments, from the room occupied in the hatching and feeding of the worms to that used for reeling and spinning silk,—and were much gratified to learn that Mr. T. is in a fair way to make the business profitable to him, as well as a neighbor to our village. We were shown some specimens of raw silk, and a few skeins of sewing silk, manufactured at Mr. T.'s establishment, which will bear honorable comparison with the best Italian.

We publish here an article from Mr. Tillingham, giving a history of his method of feeding the worm and reeling silk, which, no doubt, will be interesting to silk growers generally.

Thus may certify, that four years has passed since I first commenced feeding the silk worm, and have annually increased my stock of trees to half a million. Notwithstanding my success the past seasons, I have exceeded my expectations in this new branch of business, and the present season, I have found some trouble and difficulty and much anxiety in the last stage of the worm before spinning, which has led me to adopt a new mode of feeding.

In the first place, in the old way of feeding a large crop of worms, directly after the fourth moulting, so much food is necessary, that much water and confusion is unavoidable. And in the second place, much labor is required in frequent changing, in order to keep them clean and healthy. And, thirdly, the difficulty of preparing, in proper season, suitable fixtures for making their cocoons agreeable to the natural instinct of their species. In taking all these difficulties into consideration, I finally came to this forcible conclusion;—unless some material change should take place in the management of the worm, in the manner of feeding, &c., this important branch of industry could not well be carried on to much advantage in this country; therefore I ventured the following experiment.

I fed my worms as formerly in my nursery room, as we call it, about 20 by 40 feet, upon thin board shelves, two or half feet by four, until they arrive from the fourth moulting; at which time they are removed upon these shelves into the cocoon room with the litter that has accumulated since the third moulting. The said cocoon room is constructed long and narrow, 140 feet long and 18 wide, and as low as will admit of convenience. The frame of this building consists only of bevel posts and rafters, six by eight feet apart. The posts are well set in the ground, and the common earth constitutes the floor. The feeding frame is four feet wide, to admit the feeding sheet the longest way, and extends the whole length of the room, except between the doors for coming in and going out. This room is intended to feed, by cutting whole trees, from one to six feet in length, by laying them upon the worms with their foliage. The feeding frame is suspended from the rafters about three feet from the ground, and one tier of frames on each side, two feet from the wall, which leaves six feet alley through the middle, sufficient for a hand cart to pass with foliage. Two tier of side boards, hung with leather hinges the whole length of both sides, constitute both doors and walls, and admit of both light and air; the lower one is hung close to the ground and opened for the passage of the litter, which is very soon removed with a hoe or rake. The feeding frame is made of sawed split, one and half inches by three, and moveable staves of about one inch square, placed at suitable distances to support the trees and worms as they rise from the shelf below, which is supported by buttresses; as soon as the worms leave the shelf, it is let down to the ground with the litter. The worms are left with a

free circulation of air, and their excrement falls away from them to the ground. The trees are raised at which had on, which makes a most suitable place for their working, and remarkable for their being borne single, and less loss than any other frame I ever saw.

Actual experience has demonstrated the present season, that two hundred worms can be well fed upon every square foot of this frame, and if the whole should be filled at once we should have 200,000 to finish their work every two weeks, and the whole feeding and attendance may be conveniently done without hurry or any difficulty with the help of two men and two boys, ten years old, to pick leaves, gather cocoons, &c.

I believe it to be a safe and prudent calculation, from what we have done and are now doing, with the help we now have, that in three months time 1,000,000 of worms may be well carried through. As we have had worms hatching about every day since we commenced the present season, and consequently some winding continually, we are quite certain of success with every brood we hatch, if we know our eggs to be from a healthy stock and in a good condition.—This is all important to every silk grower. We are daily witnessing the great contrast. Eggs from selected cocoons of our own raising have done remarkably well through the season, from hatching and winding, and those we obtained, that were not selected, more or less died in the periods of moulting, and some would die just before winding.

We have good reason to believe, that the principal cause of many failures may be attributed to the care of selecting or manner of preserving. We are now selecting our best cocoons for our own stock of eggs for the next season, and contemplate to feed 2,000,000 from the same series of trees.

From the commencement, I have calculated to reel our own cocoons as soon as practicable for the manufacturers.

In visiting reeling establishments, where water is heated by steam, I thought I observed the difficulty about it, by heating a chamber of iron pipes, I am enabled to try another operation, by making a wooden box of 2 inch plank, 10 feet by 10 feet, by making use of sheet iron for the bottom. Said box is 1 feet long, 2 feet wide, and 1 foot deep. This constitutes the boiler, set on a brick arch, with a flue connected with the flue of the chimney. My small fixture consists of three of the Piedmontese Reels and one spinning machine of three spindles each, with the boiler and apparatus for heating water in the reeling pans, are all situated in a common dwelling room of 16 feet square. I have a wooden trough, made of 2 inch plank, 2 feet long, 16 inches wide, and 10 inches deep, raised 2 feet from the floor, in pans with partitions fitted to the inside of the trough, of convenient length for each reeler. A two inch tin pipe is started from the top of the boiler through the plank and is carried over the top to the bottom of the trough, runs 12 feet to the length, under the pans, and discharges through the ceiling outside; also, another pipe for letting off the water from the trough.

The same water may be used several days without changing; and in about one hour from the time the fire is started under the boiler, the water is heated by steam the right temperature for commencing feeding, and continues to keep its temperature with very little tendency. It answers the purpose intended admirably. In five weeks from the time the eggs are hatched, the silk is reeled into raw sewing, and not much inferior to the best Italian. We expect the foregoing improvements will soon be patented.

We are very much gratified with the token of approbation received from our numerous visitors, and yet would be pleased to wait on all as far as our time will allow, and spare no pains to impart information in this business, as far as we find ourselves in possession.

J. B. T.

Silk Culture.

Reasons why the people of the United States, especially the farmers, should engage in the business of silk growing.

1st. Because silk forms the heaviest item in the catalogue of our importations.

2d. Because we possess the means of doing it to better advantage than any other nation.

3d. Because the necessary skill is easily acquired and no nation ever possessed better talents to acquire it.

4th. Because the nation is under heavy embarrassments on account of excessive importations, and no

other means are so sure of success in providing the necessary relief.

5th. Because it can be effectually engaged in by all classes of people, requiring little or no capital.

6th. Because we have more spare land than any other nation, and much well suited to the growth of the mulberry, which is worn out for other purposes.

7th. Because we are already well stocked with the mulberry trees, which will be lost to the nation if not used for that purpose.

8th. Because a stock of silk worms may be obtained the first year, equal to what could be raised of any other live stock in a great portion of a life time.

9th. Because raw silk or cocoons are always surer of sale than almost any other commodity.

10th. Because it is a very certain crop.

11th. Because a pound of silk worth six dollars can be grown in less time than a pound of wool worth fifty cents.

12th. Because it will cost no more to transport a pound of silk to market worth six dollars than a pound of bread stuff or pork worth six or eight cents.

13th. Because the labor of growing a crop of silk requires only six or seven weeks, while that of almost any farming crop requires more than six months.

14th. Because most of the labor will be performed by women, children or invalids; who, though willing, are unable to perform other profitable labor.

15th. Because there are hundreds if not thousands of skillful silk manufacturers in the country who are unable to find regular employment for want of raw silk.

16th. Because the growing and manufacturing of silk has never failed to be a source of wealth to any nation which embarked in it.

17th. Because the Legislature of our State, having observed and duly weighed all the foregoing reasons, have wisely offered a liberal bounty for its encouragement.

18th. Because the American Institution, with liberality which speaks volumes to its everlasting credit, has offered, for the encouragement of literature as well as this most eminent branch of industry, a premium of fifty dollars and a gold medal for the best treatise thereunto, and a like medal for the best silk reel. The person who would not be stimulated to exertion by such reasons and liberal offers of reward must be sordid indeed. —N. F. Tribune.

A OF THE NORTH.

From the Western Farmer and Gardener.

On the Different Breeds of Sheep.

[Continued from our October No.]

Continuing the subject of sheep, I will now lay before your readers some account of what we here term the short woolled—that is, the Merino, the Saxon, the Southdown, &c. In as far as I commenced with the long wools, it may be advisable to continue the description, having reference to the length of staple, as some order of rotation is, and consequently of those already named, the Southdown will come last under notice.

The Southdown, Norfolk, Dorset, Ryeland and Cheviot, though, in fact, the old short wools of England, now occupy an intermediate space between the fleeces of Spain, Germany and New Holland, and the long wools of the Cotswold, Leicester and Lincoln. The Southdowns are a long range of hills, diverging from the great chalky stanton which intersects a portion of England from Norfolk to Dorchester, entering the county of Sussex on the west side, and continuing almost in a direct line as far as East Bourne in Pevensay bay, (being within a mile or two of the spot where William the Conqueror landed his army, previous to the battle of Hastings) and occupying a space of more than sixty miles in length with a succession of open downs, and distinguished by their situation and name, from a more northern tract passing through Surrey and Kent and terminating in the Chiltern Downs. One of the downs is a small breed of sheep have been reared for several hundred years, and from their location to they take their name. The present breed of Southdown sheep so justly admired, are indebted particularly to Mr. Elihu, for the possession of the fine form they now invariably carry. We have it upon record, that far from possessing a good shape, they were, originally, long and thin in the neck, high on the shoulders, low behind, high on the loins, down on the rump, the tail set on very low, perpendicular from the hip bones, sharp on the back, the ribs flat, not bowing, narrow in the fore-quarters, but good in the leg, although having big bone. Their improvement has not been by any admixture of foreign blood. The cross with the Leicesters and the Merinos have each proved failures. The same system that Mr. Bake-

all pursued with regard to the improvement of the breeders, was carried out by Mr. Eilman by his exertions on the Southdown with equally satisfactory results. The true principles of breeding were attended to, the sexual intercourse of the sheep regulated by selections, and in and in breeding entirely one away with. Besides improvement in shape, they acquired a better and harder constitution, with a better disposition to fatten, and became much heavier in carcass when fat. They have a patience of occasional short keep, and an endurance of hard service, scarcely surpassed by any other sheep, in early maturity inferior to none, with flesh finely grained, and wool of the most useful quality. The Southdown sheep are polled; the dusky and sometimes black color of the head and legs would almost go to prove that this was their original color, and in almost every pack, notwithstanding the care that is taken to prevent it, several particularized lambs will be dropped, and some entirely black; and there is scarcely a doubt that if left to a wild state, they would in a few years become black altogether. There are no sheep more healthy than the Southdowns. They seldom suffer from the hydrates on the brain, neither are they much subject to the rot. The following is Mr. Eilman's description of his improved Southdowns:

The head small and hornless; legs black and gray, and not too long nor too short; the lip thin, and the space between the nose and the eyes narrow; the under jaw or chop fine and thin; the ears tolerably wide, and well covered with wool, and the forehead also, and the whole space between the ears well protected by it as a defense against the fly; the eye-cap or bone not too projecting, that it may not form a fatal obstacle in lambing; the neck of a medium length, thin towards the head, but enlarging towards the shoulders, where it should be broad and high, and straight in its whole course above and below; the crest should be wide, deep and projecting forward between the fore-legs, indicating a good constitution and a disposition to thrive. Corresponding with this the shoulders should be on a level with the back, and not too wide apart; they should bow outwards from the top of the breast, indicating a springing rib beneath, and leaving room for it. The ribs coming out horizontally from the spine and extending far backward, and the last rib projecting more than the others; the back flat from the shoulders to the setting on of the tail; the loin broad and flat; the rump long and broad, and the tail set on high and nearly on a level with the spine; the hips wide, the space between them, and the last rib on either side as narrow as possible, and the ribs generally presenting a circular form like a barrel; the belly as straight as the back; the legs neither too long nor too short; the fore-legs straight from the breast to the foot, not bending inward at the knee, and standing far apart both before and behind, the hocks having a direction rather outward, and the feet meeting at the thighs behind being particularly full; the bones fine, dry, having no appearance of weakness; and of a speckled or dark color; the belly well defended with wool, and the wool coming down before and behind the knee, and to the back; the wool short, close, curled and fine, and free from spiny projecting fibres. The average dead weight of the Southdown is from 120 to 160 lbs. though they have been fed to weigh 294 lbs.; the fleece, varies from 2½ to 6 lbs., dependant, of course, on circumstances. The wool of the Southdowns, which is most reputed as a carding wool, principally used in making servants' and army clothing in England, and it was sparingly mixed with other wools for finer cloths; with the introduction of the Spanish and German wools it has changed its character, and from being one of the carding wools, has become a good combing one, and enters into the composition of flannels, hosiery and worsted goods of almost every description; heavy cloths for calico printers and paper manufacturers, woollen cordage, and coarse wools, blankets, carpets, dresses, &c., so that although it has lost cast, the most enthusiastic admirers of the old short wools, cannot but look with satisfaction at its extraordinary usefulness.

I have said that the face and legs of the Southdowns are speckled and gray—I wish farmers, however, to understand that it is not every sheep that has face and legs speckled and gray that is a Southdown; and I make this observation, for the purpose of calling attention to the importance of purchasers being particularly tenacious of buying of no persons but of those of established character, and to beware of impostors.

The Cheviot hills are a part of that extensive and elevated range, which extends from Galloway through Northumberland into Cumberland, occupying a space of from 150 to 200 square miles. The majority of

them are pointed like cones; their sides are smooth, and steep, and their bases are nearly in contact with each other. The soil, except on the very top, is fertile, and from the base to the summit of most of them, there is an unbroken and rich greenward. On the upper part of that hill in Northumberland, which is properly named the Cheviot, this most valuable breed of sheep is found, and hence again its name. It is said they have been bred there from time immemorial. A strong prejudice was once time entertained against them, but they are now spreading themselves rapidly over every part of the south of the Islands of Scotland, to the exclusion of the native black faced breed. The head of the Cheviot is polled, bare and clean, with the jaw of good length; the ears not too short; the neck round, not too long, and well covered with wool; the shoulders deep, full and wide set on; the chest full and open; the body, in general, round and full, and hams round and plump; the legs clean, of proportionable length, and well clad with wool to the knee joints and hocks; the fleece fine, close, short and thick set. It possesses very considerable fattening properties, and can endure much hardship, both from starvation and cold. The experiments that have been made in crossing the Cheviot with the Leicester and Southdowns have been entire failures, and in every instance has the original fleece been deteriorated by the system; it is, however, carried on to a considerable extent, and a great portion of the sheep on the Cheviot range, have a considerable quantity of Leicester blood in them, by which the character of the wool is being entirely altered.

EMERA.

From the Philadelphia Evening Post.

Cure for Diseases in Peach Trees.

Gentlemen—As I have understood from a source that cannot be doubted, that there are several persons employed in this State and Pennsylvania, curing diseased Peach Trees and charging for doing so, and as that information has been received directly or indirectly through me without cost to them; I feel it a duty I owe my fellow agriculturists to make it public.

The application to the trees consists of salt and salt petre combined in the proportion of one part of salt petre to eight parts of salt, one half pound of this mixture to a tree seven years old and upward to be applied upon the surface of the ground around and in immediate contact with the trunk of the tree; this will destroy the worm, but to more effectually preserve the tree I also sow this mixture over my orchard at the rate of two bushels to the acre. The size of the fruit is increased, and the flavor very greatly improved, the worm destroyed and the Yellow prevented.

I hope that other papers will place this matter before their readers so as to prevent the public from being imposed upon.

With high respect, I am yours, &c.

LYTTELTON PHYSICK.
Ararat Farm, Cecil county, Md.

Literature as a Source of Happiness.

In treating upon this subject we will take a liberal view of it, and understand, that by the term literature is meant every thing that is committed to letters. Whatever by means of these is taught us, whatever pleases the imagination, cultivates the taste, improves the mind and perfects the character, is to be attributed to literature. To it belongs not more the pretty newspapers of the day, than treatises upon mental philosophy; not more the 'latest novel,' than the fundamental and scientific works of Newton and Franklin. In fine we will take the word in its widest sense, not limiting it, as is frequently done, to works purely scientific.

If we carefully examine the subject, we shall without difficulty discover that literature is truly a source of happiness to us. In the acquisition of knowledge we obtain what is fitted to give us true pleasure at every step. We continually meet with something new, interesting and useful as we advance in our course. Our minds also become improved and strengthened in literary labors. What was once a mystery has now become thoroughly understood. The point, which we once supposed we could not gain, is left far behind. That perfection, to which we once dared not aspire, even in the wildest flights of the imagination, is now a common possession. There is even a pleasure in our toil—it brings its own reward. The store of knowledge, which we are continually adding to what we before possessed, urges us to still greater diligence, gives a laudable zeal in our pursuit, and leads us to the consumption of our hours. How does the inquiring mind rejoice at the development of each truth, that is presented—at each unexpected discovery! What are our sensations as the unbounded fields of science open before us! With clarity we renew our study. It is our joy—our life.

Again, literature is the source of happiness to us on account of rendering to a association with each other more pleasing and profitable. Since our minds are improved by literary exercises, our powers of conversation are increased and improved. And as man is a social being, whatever is added in this way is necessarily added to his happiness. One who is in seclusion is thus brought in contact with the good and great, and has his pleasure increased by associating with them.

It adds to our happiness by enabling us to do good to others. It gives us pleasure in imparting to others the rich treasures that we possess, and which we may impart without injuring ourselves, but on the contrary, rendering our own possessions more sure and fixed. With what interest does the teacher engage in the task of directing the "young idea how to shoot." And this satisfaction arises from the fact, that he knows he is performing a good action, and is benefiting the one that receives it. The writer, who publishes the result of his labor and research, and thus becomes in the highest degree beneficial to man, has his share of enjoyment. The orator stands up before the assembled multitude, points forth the triumphs of his eloquence, reproves, convinces, enlightens and exalts all around; and he too has his reward, the reward that always follows a just act.

Literature renders its possessor happy from the very fact of his possessing such stores of knowledge. It spreads its order before him information of all kinds. Its volumes are ever open before him. Even from fictitious writings he obtains a knowledge of human nature, an insight into character, and the extent and power of the imagination. In the history of the world he has a treasure unsearchable. He almost sees the scenes of the early ages acted over again while he pursues their history. He holds "high converse" with the good in the most ancient times. They speak to him in different languages—in poetry and prose. He is acquainted with every region—at home in every state. He is the keeper of many books, and especially of the "Book of books," "the book of heaven." Every thing is ready for his use; all he uses to do is to open the store-house of his mind, and let it flow forth. He is always ready for action, and able to do good.—*Maine Farmer.*

Agricultural Papers.

The vast improvements in agriculture, which have been made through out the country for some years past, have been brought about in a great measure, by the dissemination of valuable information through agricultural journals. The farmer now finds that he needs a paper devoted to his business, as well as other men. There is no class in whose affairs there are so many subjects presented, on the most of which every one may learn something new from the experience of others. Cultivators now read papers devoted to their interests, not only as a matter of pleasure, but as a matter of profit. They learn the best method of improving soils, of every description. The detailed accounts of reclaiming low lands, and of renovating worn out fields, as pursued with profit. The most successful ways of preparing manures, by which the quantity is greatly augmented, and quality greatly improved.—The most profitable modes of culture, the best productions of every description, &c. &c., and the result of the best practice in every department, is related in a paper to the community, as one neighbor would state his practice to another. This is *book farming*, at which some, even in this day of light, have too prejudice to sneer.—*Far. Jour.*

The Farmers' Cabinet.

We have had occasion, heretofore, to speak in the highest terms of praise of this publication, and especially of its engravings of animals; but we deem it an act of justice now to say, and especially that we appear not invidious towards other agricultural journals, that most of the figures of cattle we have lately seen in that work, are copies from English standard books, especially Youatt's, some of which are given as accurate and apparently original portraits of particular animals recently imported, and in no case we believe is the source acknowledged. Perhaps the Cabinet can explain this.

T

Always think what you say, though you may not always say what you think.

After kindness has failed it is quite reasonable to resort to coercion.

Folly does not always end with youth, nor wisdom begin with old age.

THE NEW GENESSEE FARMER

AND GARDENER'S JOURNAL

BATEHAM & COLMAN,
Proprietors.

VOL. 3. ROCHESTER, FEBRUARY, 1842. NO. 2. HENRY COLMAN, Editor.

PUBLISHED MONTHLY. TERMS.

FIFTY CENTS, per year, payable always in advance.
Post Masters, Agents, and others, sending current money free of postage, will receive seven copies for \$3.—*Twelve* copies for \$5.—*Twenty-five* copies for \$10.
The postage of this paper is only one cent to any place within this State, and one and a half cents to any part of the United States.
Address BATEHAM & COLMAN, Rochester, N. Y.

For Contents see last page.

PUBLISHERS NOTICE.

Our Success.—The friends of this paper will be gratified to learn that its success thus far this year equals our expectations, notwithstanding the severe embarrassments of the times. Our cash system appears to meet general approbation, and our clerks are kept busily engaged enrolling the names of our old friends (with many new ones) on our new subscription books.

Post Masters are entitled to our warmest thanks for their kindness in franking remittances. The late P. O. circular allows all postmasters to frank letters with remittances from subscribers to publishers of papers, if signed by themselves; so that our friends should write the letters and hand them, with the money, to their postmasters, who will sign and frank them.

Send us Good Money.—We entreat our friends to send us the best money they can obtain. Bills of a number of the Banks in Ohio, Penn. and other States are quite unobtainable, and we daily have to return them from whence they came.

Binding the Volumes.—All subscribers who have a complete set of vol. 1 & 2 should have them bound together. Those who can send them to this office may have it neatly done for 37 1/2 cts. Those who have vol. 2 only should by all means procure vol. 1 so as to preserve the work complete. It will always be worth more than first cost. Vol. 1 & 2 are still furnished at the subscription price—stitched in paper covers—postage the same as on newspapers.

To the Friends of the New Genessee Farmer.

The Editor has the pleasure of announcing to his friends, the Farmers in Western New York, that he is "at home" in Rochester, where it will give him pleasure at all times to see them. His respected correspondent at Wheatland tenders him the hospitality of that region. These, and all other such frank-hearted invitations, he will be most happy to accept at the earliest mutual convenience. He does not intend to stand much upon ceremony. At his period of life there is no time for a long courtship; and the banns having been regularly published, and no one forbidding them, the nuptials may take place at once. Some of the happiest hours of his life have been spent in his intercourse with the farmers at their own hospitable firesides; for no class of men has he more respect than for those in every department of life, who earn their bread by honest and virtuous industry; and for nothing has he labored with more zeal through life than the advancement of the condition of the agricultural classes, the improvement of their art, and the improvement of themselves. In this cause he has had no misgivings, and no regrets excepting regrets that he could do no more; and to this, if so it please God, the remnant of his life will be devoted.

An agricultural paper, of course, comes under the head of book-farming, and has all the prejudices to

encounter which kindle at those words. These prejudices, however, are nearly burnt out, and it is now difficult to find a man who is not ashamed to add fuel to the flame. Those prejudices have not always been without reason; but with no more reason than in respect to all the practical arts of life, book-manufacturing or book-trading. If by book-farming is meant following mere theories, or prescribing rules of practice in the art without any experience, it should have no more weight than the authority of a man who should undertake to manage a vessel in a voyage across the Atlantic without understanding the principles of navigation, or knowing even a rope in the ship. But who pretends to this? No one within our knowledge. Agriculture may be especially termed a science of facts. We go for facts; plain, determined, well authenticated facts; and we go for theories just as far as they are based upon facts, and clearly deducible from them. Types and paper furnish the best record for these facts; the best record, because it is a record open and to remain open to examination; where the facts stated can be reviewed and scrutinized, and all the circumstances connected with them tried. But it would be ridiculous to pretend that there are no settled principles in agriculture; and that after the accumulation of facts for years, we may say centuries, that no principles are determined, and that the first letters of the alphabet in agriculture are yet to be learned. It would be unworthy of us likewise, if we would deserve the character of intelligent and inquisitive men, to rest satisfied with the mere knowledge of facts in any science or art, if we can find out the reasons of those facts. Discussion, therefore, and inquiry, or what some men choose to call mere theorizing, is equally our duty as the ascertaining of facts, if thereby, we can come at a solution of the concealed operations of nature; if it should answer no other purpose, it will at least stimulate and sharpen our powers of observation and inquiry.

Our columns, therefore, will be open to the record of all valuable facts and the intelligent discussion of all important principles in agriculture. We consider some principles as much settled in agriculture as the great truths of the Newtonian philosophy; but we consider nothing as so far settled and beyond all dispute, which any intelligent mind chooses to debate, that all further inquiry must be foreclosed; and in respect to facts, we shall most scrupulously and religiously avoid the statement of any thing as fact, which is not determined in our own minds by the fullest evidence; and whenever the evidence may itself be questionable, we shall honestly submit it to our readers that they may judge for themselves.

Our columns, therefore, will be open to the record of all valuable facts and the intelligent discussion of all important principles in agriculture. the rows; hoed once and ploughed twice. Expense of raising estimated at 6 cents per bushel. The potatoes worth 15 cts. per bushel for feeding stock.

Greene.—Mr. McGuire's *Potatoes*—6 acres—340 bushels per acre, kind; Round Pinkie, and Flesh Colored—Soil, gravelly loam; previous crops, Wheat, after Meadow; a light dressing of manure to the Wheat, but none to the potatoes; ploughed once in fall and twice in spring—planted 14th & 15th June, with *whole potatoes*, one large one or two small ones in hills—about 3 feet apart each way—hoed once and ploughed once—no further care till harvest.

Greene.—JAMES BEATTY'S *Wheat*—6 Acres—53 29-60 bushels per acre. Soil rich gravelly loam—old Meadow on which cattle had often been foddered in winter—broken up in June—cross ploughed (only once) about the last of Aug.—sowed about 12th Sept. 1 1/2 bushel seed per acre—kind, White Flint.

Wheatland.—GEO. SHEFFER'S *Wheat*—7 1/2 acres—40 bushels per acre—Soil Genesee Plains—after Corn in '39 and Barley in '40—gave 30 loads of manure per acre for barley—ploughed only once after cutting barley, harrowed twice—Sowed Wheat 27th Aug. 1 1/2 bushel per acre—White Flint, rolled after sowing and rolled again 4 weeks after—then fed off close with Sheep—killed well—uninjured by winter.

Castor Bean—Castor Oil Candles

This article of culture is not new to us. We have seen it cultivated in Illinois. It is of easy culture, and has yielded a good profit when grown for medicinal purposes. The use of it referred to in the subjoined articles is new and we shall seek the earliest information in respect to it. In the meantime we request to hear from any of our correspondents, who are acquainted with the facts in the case.

The Alton (Ill.) Telegraph says: "Fifteen thousand dollars and upwards have been paid out at Edwardsville in this country, for castor beans, during the present fall and winter. The market for them is steadily increasing; and it is about as profitable a crop as can be put upon the ground."

CASTOR OIL CANDLES.—We were presented by Mr. E. Marsh, of this city, with one of his candles manufactured from Castor Oil, and were induced to test its quality with a sperm candle. The experiment resulted in the demonstration that the castor oil lasted longer than the sperm candle, and the light of the former was decidedly more brilliant and extensive than that of the latter. We could not discover the least unpleasant smell arising from burning the castor oil candle; and believe that they are well calculated to supersede entirely the use of the sperm candle. Mr. Marsh informs us they could be afforded by the quantity at 25 cents per pound, about one half the cost of sperm candles.

Portraits of Animals.—We intended to have stated last month that Mr. Sherwood had informed us that the portrait of his bull Archer, as given in the Dec. number of this paper, is not correct and does not do the animal justice. Mr. S. has promised to furnish us a correct engraving, and when he does so we will publish it with pleasure.

Mr. Fuller's cow, in the Nov. number, was still worse done; if he will obtain a good drawing we will see that it is correctly engraved and published. There is no draughtsman in this vicinity who has had sufficient experience in the difficult art of taking portraits of living animals.

IMPROVED STOCK.

Ayrshire, Durham and Native.

(From Mr. Colman's Fourth Report on the Agriculture of Massachusetts.)

Dairy Stock.

[Concluded from our last, page 3.]

12. Cows. Enoch Silsby, West Bradford, Mass. "The Durham Short Horns, I think highly of, for the improvement of our country stock, and should prefer half and three quarters blood, to full; they come in as well at two as ours at three years old; feed well on the same food as the natives, and look better in the spring; the pure blood were fair milkers and would hold out till calving, if required; I purchase at different times, ninety-eight selected, country heifers; would keep none if they did not give 7 quarts at night and five in the morning, on a bush of feed, at three years old. Many did it, but would fall off and by November, become dry or nearly so. Out of the said ninety-eight, I kept but two who would give a good measure of milk up to the time of parturition (if wanted). From these and their progeny, I have been most successful in raising, by putting the Durham Short-Horn bull to the cows. The production has been a great improvement on the natives both for milk and appearance, and I have not had a single failure. I feed principally on English hay, occasionally oat and barley straw, and roots, and bring them in at two years old as well as the natives would come it at three. I have never kept a particular account of the quantity and quality of the milk, but I know they are superior to my neighbors'; with good feed, they will give from 16 to 21 or 22 quarts per day; for curd I cannot tell, as I do not make cheese."

B. Shurtleff, of Chelsea, who has for many years kept an extensive milk farm near Boston, and who has had several of these animals of different grades, and had likewise many calves from Bolivar, the bull before referred to, says—"I have no merit as milkers above our common stock." A farmer in one of the best towns in the county, who has been some time engaged in raising this stock, says without hesitation, "he should much prefer our native stock for a dairy." A farmer in Marlborough, who is one of the best managers in the county, and who keeps a dairy of twenty-five cows, will not have a Durham among them; and the farmers in this excellent farming town are agreed in the opinion that a calf of one of the Improved Short Horns, at six weeks old, is very inferior to a calf from a native cow. A great amount of veal is sent from Marlborough to the Boston market; and the marketmen and the butchers agree with the farmers in the opinion, which is very probably, after all, mere prejudice.

From a letter received from a farmer in Rhode Island, second for his excellent management to none other within my knowledge, the following is an extract:—

"My experience in cows is confined to native stock and a cross of the native and Durham. Some of the latter have been good milkers, but not superior to the common stock. From one I probably obtained nine quarts per day on an average for the year; and from a native cow, twelve quarts for the same period. I do not know the exact quantity, but from the circumstance of having milked them myself from first to last, and from weighing at different periods, I am confident it is not overrated. Their keeping well at pasture, which was poor, was some hay daily, and perhaps three quarts of Indian meal. When confined to the barn there was an addition of three quarts of oil meal, or, as a substitute for this, twice the quantity of shorts."

I give an extract of a letter from another farmer, resident in Medford, in this county:—

"Of the Durham stock, I have but three, a bull and two cows, imported by R. D. Shepherd, in 1839. One of these cows is of no value as a milker. The other is a very fine animal in appearance, but has no milk. She had her first living calf on the 25th August last, and while the feed was good averaged about fifteen quarts of milk ten days. She has since gradually fallen off to about ten and a half per day, which she gives now (November). Her milk has never been separated from that of the native cows; I can therefore say nothing definite of its quality. I have been less curious and exact in measuring it and trying its quality from having always understood this stock to be more distinguished as beef cattle, than for any peculiar excellence as milkers."

These are the only particular and detailed statements which I have been able to obtain. My own experience, either with the full bloods or the mixed breeds, has not been favorable to them for milk or

butter. I visited some time since the yard of a farmer in this State, who has passed the highest encomiums on this stock for their dairy properties, saw his cows milked, and measured the milk. He had 5 animals,—2 as I understood, of full blood, Denton's progeny; 3 of mixed blood; and some other native cows. It was in September, and the pasture was abundant. The best animal in the yard at the morning's milking did not give more than four quarts; the second not more than three; the third, one quart and a half. It is not necessary that I should give any further minutes.

I feel myself bound in honor to state these facts and these prevailing impressions, leaving them to have the weight to which any may think them entitled.

NATIVE COWS.

I shall proceed now to give an account of some native cows, or cows raised among us, which have fallen under my observation; and I have only to add, that in my opinion, nothing is wanting to multiply such cows among us by hundreds but more care in the selection of the best, and a great deal more liberality and carefulness in feeding and nourishing them. I have referred to some of these cows in my former reports; I shall and others, and hope to be pardoned for the repetition on account of the importance of presenting this whole subject in a connected view.

I shall refer in the first place, to the celebrated Cramp cow, owned in Lewes, England, because as yet she bears the palm of all others; and because I wish to direct particular attention to the extraordinary care with which she was kept. She was not of the Improved Durham Short Horns. She was bred in Sussex from a Sussex bred cow; and it would seem as though she had some aristocratic blood in her veins, as it is said her great great grand sire received a prize cup at Peterborough, in 1726, though I think this must be an error for a much later period, as she was calved in 1799.

From the first day of May, 1805, the day she calved, to the second day of April, 1806, a space of forty-eight weeks and one day, her milk produced 540 lbs. of butter. The largest amount made in any one week, was 15 lbs. From May to June, she gave 20 quarts per day. From 20th June to 10th September, 1805 quarts. In forty-seven weeks, she produced 4,921 quarts of milk.

In the next year, from 19th day of April, 1806, the day she calved, to the 27th February, 1807, forty-five weeks, she produced 450 lbs. butter. The largest amount per week, was 12 lbs. The quantity of milk for the time was 4,137 quarts. During this year, she was sick and under a farrier's care three weeks after calving. She went dry seventeen days only.

In the third year, from the 6th of April, 1807, the day she calved, up to the 4th April, 1808, fifty-one weeks and four days, she produced 675 lbs. of butter. The largest amount made in a week, was 18 lbs. The quantity of milk given in that time, was 5,782 quarts. In the fourth year, from the 22d April, 1808, the day she calved, to the 13th February, 1809, forty-two weeks and three days, she produced 466 lbs. of butter. The quantity of milk given in the time was 4,219 quarts. In the fifth year, from April 3d, 1809, to May 8th, fifty-seven weeks, her produce in butter was 594 lbs. The amount of milk given in the time, was 5,369 quarts. The largest quantity of butter in any week, was 17 lbs. This is the most extraordinary cow of which we have any record. Though it has been presented to the public before, yet the account may not be accessible to all; and I deem it useful to state the mode of her treatment.

In the summer season, she was fed on clover, lucerne, rye grass and carrots, three or four times a day; and at noon, about four gallons of grains and two of bran, mixed together, always observing to give her no more feed than she could eat up. In the winter season, she was fed with hay, grain, and straw, mixed as before stated, feeding her often, viz. five or six times a day, as was seen proper, and giving her food when milking; keeping the manger clean, where she is fed with grains; not to let it get sour; wash her udder at milking three times with cold water, winter and summer; never tied up; lies in or out the barn as she likes; particularly careful to milk her regularly and clean. Milch cows are often spoiled for want of patience at the latter end of milking time.

I now proceed with a list of cows produced and raised among ourselves; not a distinct but a mixed race; raised under innumerable disadvantages; yet showing, in a remarkable manner, what valuable materials we have to work with.

1. The Oakes Cow in Danvers, Mass., produced in 1813, 180 lbs. of butter; in 1814, 300 lbs.; in 1815,

over 400 lbs.; in 1816, 484½ lbs. During this time one quart of the milk was reserved daily for family use, and she suckled four calves for four weeks each, in the course of those years. She produced in one week 19½ lbs. butter; and an average of more than 16 lbs. of butter per week, for three months in succession. The largest amount of milk given by her in one day, was 4½ lbs. She was allowed 30 to 35 bushels of Indian meal per year, and all her own skimmed milk and most of the buttermilk. At one time, the owner gave her potatoes, which increased her milk, but not her butter. In the autumn, he gave her about six bushels of carrots.

This cow came into the possession of Josiah Quincy, then of Quincy, who had at the same time a large cow of English blood, the progeny of a celebrated imported cow, and owned by John Welles, of Dorchester, whose improved stock are held in high estimation; but as to their legitimacy in the Short Horn family, or the strict purity of their blood, I cannot speak with confidence. On a trial of this Oakes Cow with this English Cow for a fortnight under the same food and treatment, the English Cow produced 16 lbs., the Oakes Cow thirty-two lbs. and a few ounces in that time.

2. The Nourse cow, owned in North Salem, made 30 lbs. of butter in one week, and averaged 14 lbs. butter per week for four successive months.

3. The Haverhill heifer, two to three years' old, produced 14 lbs. of butter in a week after her calf was killed at six weeks old, and more than 18 lbs. of butter in the ten days after her calf was killed.

4. Cow owned by John Bart, in Salem. 1822. In 174 days the weight of milk was 7611 lbs. No. of quarts, beer measure, 2965½
1823. In 268 days, weight of milk was 7517 No. of quarts, beer measure, 2923

The sales from this cow, including the calf at 5 dollars and milk at 5 cents per quart, in 1822, was \$153.25. In 1823, \$151.15.

5. Cow. John Stone, Marblehead. From June to October, this cow averaged 11 lbs. of butter per week.

6. Cow. N. Pierce, Salem. 3,528 quarts of milk per year, nearly 10 quarts per day.

7. Jeremiah Stockney, Rowley. 19 quarts daily; calf at 6 weeks old weighed 196 lbs.; gain 2 3/4 lbs. per day.

8. Cow. Isaac Osgood, Andover. 17 quarts of milk per day; made 56 lbs. of butter in the month of June.

9. Cow. S. Noah, Danvers. In 148 days from 2d May, gave 587½ gallons milk; more than four gallons per day for that time. This cow calved on the 29th of April, and in the 148 days succeeding the 2d of May, she yielded 605½ lbs. of milk.

10. Cow. T. Flanders, Haverhill. From 20th April to 22d September, besides 404 gal. one milk used for family, made 163 lbs. 4 oz. butter.

11. Cow. Daniel Putnam, Danvers. "This cow calved May 21st. The calf was sold June 20th for \$7 62½. During the 30 days that the calf suckled, she gave more than her milk 17 lbs. of butter. From June 20th to September 26th (fourteen weeks) she gave 337½ lbs. of milk, or more than 34 lbs. 6 oz. per day. The greatest quantity on any one day was 45 lbs., or 17½ quarts. The weight of a quart of her milk is 2lbs. 9 oz. The greatest quantity in one week was 288 lbs. The quantity of butter made in the same fourteen weeks was 139 lbs. The greatest amount in one week was 12 lbs. 2 oz."

12. Cow. Owned by William Osborn, Salem. The milk of this cow from January 24th to April 10th, was 3127 lbs. varying from 33 to 48 lbs. per day, averaging 40½ lbs. per day during that time.

13. Cow. Owned by Richard Elliot, Danvers. This cow's milk gave 16 lbs. of butter in one week; and she yielded on an average from 15 to 18 quarts per day, beer measure, for a length of time.

14. The yield of a cow owned in Andover is remarkable. Her origin is not known, but her appearance indicated a mixed blood; and I was led to believe she partook of the Yorkshire blood, a race of cattle which I have found in the neighborhood of Moultonborough and Canterbury, N. H., but whose introduction I am not able to trace.

In 1836, besides supplying the family with cream and butter, there were sold 127½ gallons milk at 14 cents per gallon, \$17 88
160 lbs. butter at 25 cents, 41 50
Calf sold, 8 00

\$67 38

"The keeping was good pasture and swill of the house, including the skim milk, with three pints of meal per day." These statements show, in a strong

light, the difference between a good and a poor cow; and the utility of liberal keeping.

15. A cow of Samuel D. Colt of Pittsfield, from 1st December to 26th April, 148 days, produced 193 lbs. of butter.

16. A cow owned by R. Campbell of Pittsfield, has yielded 285 beer quarts of milk per day.

17. A cow owned by Hosea Merrill, gave 30 beer quarts of milk per day.

18. A cow owned by D. Fenn of Stockbridge, 8 years old, produced in one week 12 lbs. 9 oz. butter. During the same time, 10 quarts of the milk were sold, and in addition cream and milk were used freely in the family.

19. A cow owned by Calvin Davis, 4 years old in the spring of 1838, in 172 days produced 225 lbs. butter, and fattened a calf. An accidental injury to the cow prevented a continuance of milking butter.

20. Two cows of Wm. Dewey, of Alford, in good season, averaged, for a length of time, 14 lbs. of butter each per week.

21. A cow belonging to the late Dr. Hyde, of Stockbridge, for some time produced fourteen pounds of butter per week.

22. Two cows in Vandensenville, produced 14 lbs. of butter each per week.

23. A cow belonging to — Millard of Egremont, produced 14 lbs. of butter per week.

24. From two cows belonging to Russell Brown in Cheshire, besides the free use of milk and cream in the family, 90 lbs. of butter were produced and sold in three weeks, and in four successive weeks 114 pounds.

25. A cow owned in Stockbridge, by Stephen Willard, produced as follows:

In 321 successive days 231 lbs. butter.

" 251 " " 293 "

" 306 " " 318 "

911 days 912 lbs.

"The above is exclusive of 25 lbs. made while fattening three calves." He adds "my method of keeping has been grass only, from spring to fall. In the fall I begin with pumpkins and potatoes, and feed moderately during the time she gives milk. An account has been kept for only three years; but it would not vary much from the above, for the two seasons I have had her, except the present season she has been farrow." This cow is now eighteen years old, "and will calve again about the middle of February."

26. Two cows owned in Pittsfield, produced each 50 lbs. of milk per day; and one other 32 lbs. at a milking.

27. A cow owned by Thomas Hodges, in North Adams, produced last year 425 lbs. of butter; 400 lbs. of this amount were made in nine months. Her feed consisted of one quart of rye meal, and half a peck of potatoes per day; and very good pasturing.

28. A cow owned by Joseph F. Upton, of Ashfield, Franklin Co. From the first of April, 1837, to the middle of February, 1838, her product was 335 lbs. 15 oz. From the 9th of May, 1838, to the 28th December, 1838, she had produced 303 lbs. 3 oz. of butter, and was still milking at the rate of one lb. per day.

The owner adds, "In the year 1837, I killed my calf at three days old, and gave my cow the skimmed milk through the summer. I commenced the first of October to feed on potatoes. I gave her about one peck per day boiled, as long as she gave milk. In the year 1838, I fattened my calf and killed it at four weeks old. It weighed 75 lbs. She has had nothing but grass this year, until the first of October; since then I have fed her with one peck of boiled potatoes per day. My cow is seven years old last spring." Her winter keep at present, while giving milk, is as much hay as she will eat, and one peck of boiled potatoes per day.

29. Cow. N. Sandersen, Waltham, Mass., 1828. Thirteen and one half lbs. butter per week through the season, on an average.

30. Cow. Luke Fisk, Waltham, Mass., 1824. Made 12 lbs. butter per week.

31. Cow. George H. Hardy, Waltham, Mass., 1826. Averaged, for four months, 11½ pounds per week.

32. Cow. John White, Dedham, Mass., 1826. Gave 12 pound butter six weeks in succession; one week 12 pounds 13 ounces; three months, averaged 10½ pounds per week; gave 18 quarts milk per day, at times.

33. Cow. James Robbins, Watertown, Mass., 1827. May and June, from 10 to 13 lbs. butter per week.

34. Cow. Ralph Hastings, Dorchester, Mass., 1827. Eighteen quarts per day—average 14 to 15

quarts. Before grass feed in April, the cream of two days made 2½ pounds butter, and was made from 1 to 16 quarts of cream. Two or three minutes in churning. This was the mother of Mr. Jacques's famous Cream-pot-bread.

35. Two cows—Rev. Mr. Phenix, Cluopee Mass., 1828; for several weeks averaged 20 lbs. per week, besides what milk and cream were used in the family.

36. Cow. W. Chase, Somerset, R. I., 1831. Most of the season, 20 quarts milk daily; averaged nearly 11 pounds butter per week during the season; 120 pounds made in ten weeks.

37. Cow. Isabel Graves, Northampton, Mass., 1830. Four years old; one week, 13 pounds 9 oz. butter.

38. Cow. L. Homer, Bedford, Mass., 1830. 11 pounds butter per week.

39. Cow. Josse Putnam, Danvers, Mass., 1830. Averaged more than 208 pounds butter each in the season; highly fed.

40. Six cows, J. Curtis, Marblehead, Mass., 1830. Averaged over 181 lbs. butter each in the season, without extra feed.

41. Cow. W. Dickinson, Deerfield, Mass., 1830. One week, 14 lbs.; first eight weeks after calf was taken away, made 96 lbs. Six quarts of milk made one pound of butter.

42. Cow. H. G. Newcomb, Greenfield, Mass., 1830. From March 27th to May 25th, made 100 lbs. of butter, and reserved 160 quarts milk. In 14 days, made 20 3/4 lbs. butter.

43. Cow. D. W. Greenfield, Mass., 1830. In one fortnight made 25 lbs. butter. In May 1832 she produced, in one week, 15½ lbs. butter. Average daily weight of milk, 47 lbs. Measured one day 36 beer quarts.

44. Two cows — Hart, Shelburne, Mass., 1834. Besides milk and butter used for a family of three persons, they sold from these two cows, in one season, upwards of 400 lbs. butter; feed, grass only. In June, they made in one week 23 lbs., one week 25 lbs., one week 25 lbs.

45. Cow. — Barrett, Northampton, Mass., 1830. This cow milked, for one fortnight, every eight hours; at each milking has yielded a pailful, holding 10 quarts—the weight of the milk averaging daily 40½ lbs. Her milk has yielded daily 2 lbs. 6 oz. butter, making 32 lbs. 6 oz. in 14 days. From one milking alone, 1 lb. 6 oz. was made, which will give 4 lbs. 2 oz. butter in one day, from one cow; the butter was of a superior quality, and brought a high price in the Northampton market.

46. A cow owned in New London, Connecticut, yielded 10 quarts milk per day, for 14 successive months.

47. Cow. I. G. Tyler, Bradford, Mass., 1830. From April 1 to Sept. 28, produced 154½ lbs. of butter. In the second week in June, she yielded 126 quarts of milk, beer measure, at the rate of 18 quarts per day for that time.

48. Cow. C. C. Sewall, Danvers, Mass., 1830. From the 26th of June, in 95 days she gave 3159 lbs. or 127½ quarts beer measure. The greatest quantity in one week was 116 quarts; in one day, 17 quarts, 1 pint. The daily average quantity was 13 quarts.

49. Cow. Albert Johnson, Lynn, Mass., 27th March, 1840, when she calved, to 25th September, 1840 days, she produced 6540 lbs. of milk, or 273½ beer quarts, averaging nearly 15 quarts per day. The largest quantity any one day was 52 lbs. or 20½ quarts. She had good pasturage until the drought in summer, and then some hay and one bag (four bushels) of shorts.

The account of this cow for part of the present year is as follows. From March 29th to September 30th, 1850 days, she has given 6783 lbs. of milk, equal to 271½ quarts, averaging 14½ quarts per day. The largest quantity given in one day was May 9th, 51½ lbs., equal to 20½ quarts. She has been sick a part of the season, by browsing the leaves and branches of the black cherry tree, which has occasioned some diminution of her milk.

50. Cow. Charles F. Putnam, Salem, Mass., From November 15, 1839, to November 13, 1840, she produced 4214 quarts of milk, beer measure, being an average of 12 quarts per day through the year. Mr. Putnam writes to me, "that the first month this summer, (1841), with two quarts of meal per day, she averaged eighteen quarts of milk per day. I am confident that the cow will give twenty quarts per day in good fair feed. She was milked till within three weeks, and could have been milked to the time, of calving."

51. Cow. Hobart Clark, Andover, Mass., 1830. 14 quarts 14 pounds.

52. Cow. Julius Smith, Cheshire, Conn. This heifer, two years old, averages 18 quarts of milk per day.

53. Cows. Spencer, Guilford, Conn. These cows average 14 quarts daily through the season.

54. Cows. Allen, Cheshire, Conn. Eight cows. 15 quarts of milk daily.

55. Cow. Shelburn, Vt. Has yielded 26 quarts, beer measure, in a day; and at two milkings in 24 hours, produced 3 lbs. 14 oz. of butter. This cow was raised in Vermont. Some persons, from her great product, call her English; but the admixture of blood is very small if any; and if any, it is not known, whether Dutch, or Ayrshire, or what. There is nothing but her color, which indicates any difference from our best formed native stock. She has some progeny by an Ayrshire bull, which are very promising.

56. Cow. S. Henshaw, Springfield, 17½ lbs. of butter per week, and in one case, 21 lbs. of excellent butter. In 14 days, it is 4 days and one milking she produced 14 lbs. 3 oz. of butter at the rate of 22½ lbs. per week. I had in a former publication marked this cow as a cross from a Durham bull; but I was misinformed. Mr. H. tells me she was a native cow without mixture of foreign blood.

57. Cow. West Springfield. This cow in sixty days produce d 2692½ lbs. of milk, averaging 44½ lbs. per day. This was equal to 22½ quarts per day for that time. She repeatedly produced over 50 lbs. and sometimes 51 lbs. of milk per day. I have the exact daily returns for the time.

58. Cow. O. Morris, Springfield. "The summer after she was seven years old, the quantity of butter made from her between the first day of April and the first of September, five months, was 206 lbs. During the time, we used milk and cream in the family freely. Some weeks we have made 14 lbs., exclusive of milk and cream used for family purposes. I have often weighed her milk in the month of June, and she has frequently yielded 31 lbs. at one milking at night. We have been particular to have her milked in the summer at five o'clock in the morning, and at seven o'clock in the evening, and always by the same person. I think much of regularity in the times of milking; and that one person only should be permitted to milk the same cow the same season. My cow has always had a good milker, and her milk has been rapidly drawn. Her food in the winter is good hay, and in addition thereto from 2 to 4 quarts of rye bran at noon. I feed and give her water three times each day. In the summer, besides the pasture, she has 4 quarts of rye bran at night. From the experience I have had with this cow, I feel quite sure that many cows which have been considered as quite ordinary, might, by kind and regular treatment, good and regular feeding and proper care in milking, have ranked among the first-rate."

59. Cow. Roxbury. This cow, besides taking care of her calf, produced 3975 beer quarts of milk in one year or before her next calving, which was within the year.

60. Cows. J. P. Cushing, Watertown. "There has been no account kept of any of our native cows. Several of them, however, on grass, and also in the winter (soon after calving) have given 20 quarts a day for a month or more. Several of our native cows, particularly two which you recommended, give a greater quantity of milk than any of our imported cows, with single exception."

61. Cow. Page, Danvers 13 lbs. butter in one week; 20 lbs. in three successive weeks.

62. Cow. B. Shuttlefield, Chelsea. Supposed to be of the Galloway breed, small cow, has given 21 quarts per day.

63. Cow. Daniel Breed, Lynn. "She is six years old. She gives now (Nov. 19,) on grass and 13 peck of roots, six quarts of milk per day. She has not had any hay or meal this fall, and all the hay consumed by her last winter, was 2900 lbs. without bran." She calved last April, and comes in again March 12th. She gave in June an average of 45 lbs. of milk per day, and has given 2490 quarts the last seven months. She is milked until within a few days of her calving. What is remarkable about the cow is her small size, and its requiring so little food to produce so much milk." The above measures are all ad and beer measure.

64. Cow. "George Goodnow, of Southborough, in the county of Worcester, keeps 10 cows upon his farm. He has kept an accurate account of their produce for a number of years. The amount of butter made from these 10 cows in the season of 1839, was 2172½ lbs. The amount sold 2028 lbs. The amount used in his family, 144 lbs. During the month of June, the same season, the 10 cows averaged

9 lbs. each per week on grass feed alone. He has a number of cows that have made 104 lbs. per week and one that he has made 114 lbs. from. After the 1st of December he makes no butter, but sells his milk during the winter, the account of which has been mislaid. His calves suck till they are 7 weeks old, then they are mostly slaughtered. The cows are dry from 2 to 3 months previously to calving. In the season of 1840, the butter made from 10 cows was 1965 lbs. Amount sold, 1831 lbs. Amount used in the family, 134 lbs. Mr. G. had not footed the account for the present season, (1841,) but he said it would not probably vary much from the two previous years. The cows are all native. You may rely upon the above being correct.

65. From 30 cows in Cheshire, Berkshire county, all native cows, an average of 435 lbs. of new milk cheese has been produced to each cow, and 10 lbs. butter, or 300 lbs. in the whole in a season.

66. Two dairies in Cheshire: one of 21 cows, produced 626 lbs. of new milk cheese, and 1700 lbs. of pork were made on the same farm, half of which was to be credited to the cows: one of 18 cows, produced 623 lbs. of new milk cheese in a season, and 1000 lbs. of pork were made the same season on the same farm. Two quarts of rye meal were given to each cow two months the first of the season, and one quart for one month during the last of the season. Most of the time they had their whist to rich.

I might greatly enlarge this list by a mention of other native cows as remarkable as those to which I have referred; but here I shall submit the case. The beauty of the Improved Durham Short-Horns and their perfection of form are admirable. They come with good keeping early to maturity. They have a tendency to keep themselves in good condition; and with extraordinary feeding and care, they arrive at a large size, and some individuals, all points considered, have surpassed any thing within my knowledge. The Chelmsford ox, a half-blood Durham, whose pedigree is not known, which was sent from this country to England for exhibition three years since, was pronounced by competent judges the finest animal of the kind ever seen there. His live weight was reported as not far from 3700 lbs. The Greenland ox was nearly as heavy, and singularly beautiful. A native ox exhibited in Boston, in 1840, did not differ much from these in size, fullness, and weight; but compared with them in appearance, he was misshapen and deformed. The Durham cows, in general, especially the selected ones, which have been imported on account of those qualities, are large milkers; but their milk seems generally inferior as to richness or butteraceous properties. The milking properties of Mr. Whitney's stock at New Haven, are very remarkable. The Durham cows are large animals, and should be expected to secrete largely of milk; but many of them, however, are inferior as milkers; and, upon as calm and impartial a view of the subject as I can take from my own personal observation, I cannot pronounce them, as a race distinguishedly preferable to all others for their dairy qualities. I have come to this conclusion with very strong prejudices in their favor; and as I measure my words in this case, I wish to be judged only by what I say.

Whenever a Short-Horn cow proves an inferior milker, the enthusiastic advocates of the race are pleased to tell us that it is because she has no pedigree, and is not a herdbook animal; but admitting that her genealogy is somewhat mixed, it is singular that the virtues of the blood should not show themselves to a degree, and that the impurity or defect should always predominate. It is certain, however, that many mixed bloods have in every respect exceeded many of the pure bloods.

In regard to what we call our native stock, in which various bloods and breeds are intermingled, many of them are indeed miserable in appearance, in shape, in condition, and every other quality. This comes in general from neglect and indifference, because we kill or sell to the butcher our best calves, and commonly leave what we do attempt to raise, "to shift for themselves." Yet at the same time, without presumption I think, New England may challenge the world to produce finer teams of oxen, by fifties and hundreds of pairs, than there to be found at our cattle-shows. Let any intelligent judge of stock go into Worcester county, Mass., into New Haven and Hartford counties, in Connecticut; or especially to Sacerapoe, in Maine, where ox teams are constantly employed in carting lumber to Portland, and if he will find any superior oxen for labor and condition than are to be found there, he would do a signal favor to the agricultural public in letting us know where we may look for them. I have seen none. I believe we could search the world over in vain to find any.

Our native cows are of every variety, but there are several parts of the State where, though it cannot be said that any scientific or systematic improvement has been undertaken, yet by a long-continued selection from the best, whole families or breeds are to be found distinguished for their excellent properties as dairy stock. The list of native cows, which I have given, shows conclusively that we have those which, for the quantity of milk they give, are scarcely inferior to any; and for the amount of butter and cheese which they produce are surpassed by none. The numbers referred to prove that they are not rare.

Whether any thing would be gained by substituting the Improved Short-Horns for our present stock, is, to say the least, questionable. The Short-Horns are great consumers. Though animals do not always consume in proportion to their size, yet this must be considered as a general rule. They require most particular attention and liberal feeding to bring them to maturity, though we admit that they arrive at maturity early. Many of the Short-Horned premium young animals which have been exhibited at our cattle-shows have had the benefit of two wet-nurses for six months. Most of our native calves are put off with two teats, and at eight or ten weeks old are turned adrift into the pasture to live or die as they please. Our own stock has never had fair play, and it treated in the same manner as the best Short-Horn stock they would not perhaps fall so far behind them as might be supposed. Our pastures are in general short and our winters long. A small race of cattle, therefore, and a more hardy stock would seem better adapted to our condition.

The London milk establishments are mainly supplied with the Short-Horns, because, it is said, they give more milk, and after becoming dry, take on flesh sooner than other races, and are therefore more easily disposed of to the butcher. The size of these animals would naturally indicate a larger yield of milk, and, at the same time, a greater consumption of food. But the yield of milk is put down at an average of nine quarts daily. These are presumed to be wine quarts, and deducting one fifth, it does not much exceed the yield of some milk establishments among us. Besides, in the London dairies, cows are not suffered to become with calf.

One of the most extraordinary Short-Horn cows known in England, it is said, produced 374 pounds of milk in a week; 17 pounds being an average quantity made in any one week. This is quoted as quite remarkable; but this, as far as it goes, does not equal the Oakes, the Nourse, the Adams, or the Springfield cow. One of the best-informed and most ardent advocates for the Short-Horns, the late Henry Berry, remarks:—"That their milk does not contain the same proportionate quantity of butter as that from the Long-Horns, the Scotch cattle, or the Devons, is probably true; but we have reason to believe that the difference has been much exaggerated, and is more than compensated by the additional quantity of milk." Whether this additional quantity of milk can be procured without an additional quantity of food, is a question which naturally arises, but which I have no means of answering with confidence.

The quantity of cheese made in a year from a cow in the celebrated cheese district of Wiltshire, Eng. is thus stated. "The quantity of cheese that is made from each cow in this district is greater than is common in any other cheese-making country, sometimes as much as 1½ cwt., or 5 cwt. per cow, seldom lower than 3 cwt. Perhaps 3½ cwt. is a fair average in a good cheese-making year on every cow that calves in proper time." In the famous district of Cheshire in England, the average amount of cheese to a cow, is stated at 2½ cwt. The old breed of Irish cattle, much valued for the dairy, will produce from 84 to 112 lbs. of butter per year; a very good cow will yield 14½ cwt. that is 168 lbs. net. Of the Ayrshire cows, kept in the highest condition for giving milk, it is stated that the yearly average in milk may be 650 gallons or 2600 quarts, (wine measure 1 pint more is intended) and 90 gallons will make 21½ lbs. of butter, or 15 quarts (wine measure) to a pound. In another case it is said "that a well fed cow of a good breed, will produce on an average 180 lbs. of butter in the season; though the common calculation is 150 lbs. In the Epping district, where there is an indiscriminate mixture of Devon, Suffolk, Leicester, Holderness and Scotch, the calculation in a well managed dairy amounts to 212 lbs. per year to a cow. In one case in Shessex, upon an actual trial, the cows produced only 136 lbs. per season."

As far then as we can depend on these accounts our own native cattle for dairy stock will not suffer by comparison with the best English stock of any of those races most distinguished for their milking pro-

perities. Our own Cheshire cheese dairies certainly yield the palm to none.

The cross of the Durham Short-Horns with the Devon has produced in many cases an excellent stock. But if of no other value to the country, their introduction will prove an immense benefit by showing our farmers what can be done in improving the size, form, and condition of their own stock, by a most careful selection from the very best, by persevering attempts to amend defects and engrain good practice in the animal constitution, and by constant care and good keeping.

It cannot be denied that a vast proportion of our cows are wretched in their form, health, and condition. There is no reason on the other hand to doubt that by breeding only from the best on both sides, and by a liberal mode of keeping, we may produce a dairy stock, and a stock for labor, as well adapted to our pasture, climate, and husbandry as can be found. Perhaps I should be authorized to add for beef also, that is, producing as many pounds according to the expense of their keep. The average weight of bullocks slaughtered at Smithfield, the great cattle market of England, is 656 lbs. At Brighton in this county, the average weight of oxen is 775 lbs., and of steers 600 lbs. each. The last is thought by some persons to be overrated. The weight used at Brighton is not weight; one hundred weight being now reckoned at 100 lbs. avoirdupois.

Sale of Cream Pot Stock,

At the Farm of S. Jaques, Charlestown, Mass.,
January 11th, 1842.

We annex a list of the animals sold, as numbered in the catalogue, with their ages and prices, which they brought. The result created almost universal disappointment. It was not in our power to attend the sale; but it is cause of much regret that, after the pains which Mr. Jaques has taken to rear a race of animals whose richness of milk peculiarly fitted them for dairy stock in New England, there should so little reward have been found for his exertions and so poor encouragement presented to future efforts. That a bull of admirable character and points, for which, as we have understood, 700 dollars have been more than once offered, should be knocked off under the hammer, for 61 dollars, is a sad disappointment.

The time of year for the sale was unfavorable. The high price of hay was against success; the scarcity of money still more against it. A forced sale, as this was understood to be, is always unfavorable. How far the animals presented could be warranted secure of the excellent properties of their ancestors, we are not able to say; and have learned that some doubts on this point operated essentially against them; but the extraordinary excellence, we mean especially the richness of the milk, of the best among them, there can be no question whatever. The fortunate owners of the best animals will, we hope, do them full justice. We only wish that Mr. Jaques could have found a more essential reward for his exertions than the satisfaction of having led the way; and we believe with much success, in endeavoring, on enlightened principles of breeding, to form out of the materials which we have at hand, a stock adapted to the purposes of the dairy and to the climate and pastures of New England.

Book Farming—Agricultural Chemistry.
"Strike but hear"—Aristides.

Professor Liebig has truly said that a perfect system of Agriculture cannot be understood without the application of scientific principles, as the whole system is based on the exact acquaintance with the means of vegetable nutrition.

The same learned author is establishing the doctrine that plants receive almost all their support from the atmosphere, has realized the astounding fact, that Agriculture the first of all arts and employments, and almost the only one which is certain to give health and comfort to its votary, is now in this age of great discovery and improvement, not only far behind almost every other art, but that it has not yet laid aside the swaddling clothes of its infancy.

Ask even a tolerably intelligent farmer what is the fault of sandy land, he will tell you it leaches the manure; but agricultural chemistry will tell him, and practical experiment confirm the fact, that manure does not infiltrate, unless it is where the superincumbent mass is too great to admit of the escape of its gasses to the atmosphere. The want of fertilizing power in sand is doubtless owing to its having no power to generate carbon, or to retain ammonia, for the food of the plants sown upon it; without the aid of lime, clay, or ashes; animal or vegetable manure will if constantly applied, supply the deficiency of the absent earths, but after fermentation is over, the inertness of the sand again prevails.

It strikes us that there is nothing that our farmers understand so little, as the economy of manures; it is generally supposed that the more a field of corn is manured, the greater will be the crop; as Indian corn is one of the grossest feeders in vegetable life, it produces in proportion to the aliment it receives; but as that aliment comes from the atmosphere, a moderate quantity of the most stimulating manure properly applied, with a frequent stirring of the soil, will be found to produce a better growth than a larger quantity of the most

posed that when the weeds are subdued, the hoe or cultivator has no office to perform; but nature reverses this decision as actual experiment invariably proves.—The frequent stirring of the earth lets in the oxygen of the atmosphere, which is converted by the *humus*, in the soil into carbonic acid, to be absorbed by the plants.

It should be the object of every farmer to understand the substance which goes to form the plants he is about to cultivate, in order that he may know how to apply such substances to the soil as are found to be the inorganic constituents of the plant he proposes to grow. Hence, as wheat straw contains twice as much potash as barley straw, and barley straw twice as much as oat straw; it is to the interest of the farmer to spread his ashes on his wheat fallow, rather than on his oats. It is said that those plants which contain the least alkali, may be the longest cultivated on the same soil; hence by covering old meadows with a coat of ashes, you quicken fertility by restoring that potash which was carried off by the preceding crops.

Lime is a constituent part of wheat; hence in those sections where there is no limestone, wheat only grows well as a first crop. It would not succeed then, were it not for the presence of lime and potash in the ashes of the great mass of vegetable matter buried in clearing the land.

The doctrine that *humus* is extracted from the soil by the roots of plants seems when submitted to a strict examination to be untenable. This opinion, that all vegetable nutriment comes from the atmosphere, seems of late to be corroborated by actual experiments in France. The *Phalange a Fourier* asserts on the best authority, that wheat has been grown to great perfection on a "pane of glass," without other aid or covering than a thin layer of wheat straw. In this case nature, seems wisely to provide in the *debris* of the plant, the elements for a perfect reproduction of the same plant by atmospheric aid alone. Hence the farmer should take the hint that wheat straw forms the most valuable base for manure to be returned to the wheat fallow; and that the straw alone if it could be properly distributed and retained on the sown surface, would while it prevented winter killing, secure an abundant crop.

When we reflect on the great developments which agricultural chemistry is now making for the benefit of agricultural economy; the more progressive march of our moral population in mental culture; we cannot but feel that the much wished for era, has commenced when two blades of grass are to be made to grow, where one now hardly vegetates; when instead of travelling a mile over the most fertile portion of the earth, without seeing more than two or three human tenements, with fields and fallows whose unpromising appearance hardly redeem them from the desert; we shall find every high road a continuous rambling village, animated by a rural population whose busy intelligence in the agricultural art, will offer to the eye of the beholder the interesting spectacle of the maximum of vegetable production. The problem will then be solved of what a single acre can be made to produce, by examples without number.

Waterloo, N. Y.

S. W.

The Ontario Agricultural Society.

Will hold their annual meeting and winter show at Canadawaga on Tuesday 8th Feb. current. We design, extraordinary excepted, to be among the Live Stock on the occasion, not for exhibition, still less for premium; surely not, for we do not belong to the county; but that we may, if it be allowed us, have the pleasure of making the acquaintance of some of the best farmers in the State; and joining in the festivities of one of the best day's in the year, the Farmer's Holiday.

Premiums are then to be awarded, (three) on each article, on crops of Winter Wheat, Indian Corn, Barley, Oats, Peas and White Beans. Next, three pre

Competitors for premiums on Winter Wheat to produce written statements of the kind of soil, whether clay, sandy, gravelly or otherwise. Of its location, whether level or rolling, protected by woods, orchards or hills. The manner the field has been cultivated for the last two years, whether any course of rotation of crops is pursued, and what; whether manured, and when, what quantity and of what kind. How many times ploughed and when, deep or shallow, how many times harrowed. When sowed, what kind of seed, and how much; seed covered with a plough or harrow; what time ripe and harvested. Specimens of the wheat are to be exhibited to the Committee.

Competitors on Indian Corn, Barley, Oats and Peas to produce like statements of soil, system of rotation, if any, preceding the crops, manure, how applied; when and how much, how ploughed, and number of times; quantity and kind of seed, when sowed or planted. What further culture; when ripe and harvested, quantity of produce, accompanied with specimens.

Corn to be weighed, seventy five pounds of ears of corn allowed for a bushel.

Barley, Oats and Peas to be determined by standard weight.

Satisfactory evidence will be required, as to quantity of land, amount of crops, way ascertained, &c.

To be awarded by the Committee.

In respect to roots statement's in regard to the soil and culture are to be given as for corn—the roots are to be weighed after the tops are removed.

Six premiums are likewise to be awarded on red clover Seed—three to the farmers who produce the greatest quantity; three to the farmers, who produce the greatest quantity on an acre.

The premiums on Animals we subjoin at large as their appearance now is not too late to induce competition.

The Fat Cattle will be exhibited on the Public Square, in front of the Court House. The Fat Sheep will be exhibited in the lot adjoining the south west corner of the Public Square.

All samples and specimens of Grain, Roots and Clover Seed, will be exhibited at the Court House.

Competitors for premiums, are requested to have their Animals and other articles at the appointed places, and ready for inspection, by 11 A. M.

Wind Mill.

The subjoined is from a gentleman on whose good judgement and faith entire reliance may be placed. The best form of a wind mill must be of much importance in places where water power is wanting.

Mn. HENRY COLMAN—

SIR—I observe in your first number the plan for a Horizontal Wind Mill, which is recommended superior to any form hitherto discovered. Should any person have occasion to erect a wind mill, even in your distant part of the country, I think he would be well paid for his journey to Roxbury before he undertook it, to examine a plan of one for which Capt. Stephen Glover has obtained a patent. I believe there has not been one erected yet on this plan; but I think he would grant any person the privilege to erect one, that it might be proved superior in simplicity and durability, and unaffected by gales or storms, and that it will run equally steady and rapid in a gentle breeze as in the gale.

I am with respect and esteem,

For the New Genesee Farmer

Durham Cows as Milkers.

Messrs Editors—I noticed in the New Genesee Farmer of a few months ago, some remarks of Mr. Colman concerning Durham Cows as milkers. Mr. C. speaks well of the Durhams in most respects, but remarks that he yet wants the proof of their being the best breed of cattle for the dairy business. For my part, I am satisfied that they cannot be surpassed by any breed in America; and I think if Mr. Colman would lay aside all prejudice and take the pains to inform himself that I have, he would be of the same opinion that I am.

I was raised in the State of Vermont, where the dairy business was carried on extensively, and I have taken great pains to obtain information respecting this branch of business, and I can safely say that I have never seen any breed of cattle that would equal the Durham for the dairy. I have some half, and three quarters blood, and some of my neighbors have the full bloods, and I challenge Mr. Colman or any other gentleman to produce their equal among native cows, in the quantity and quality of milk. I have a Durham heifer, two years and a half old, that has often given 31 quarts of milk per day, and that of a good quality; and I have some others almost equal to her. One of my neighbors has a full blood Durham cow that he values at \$300; he offers to give the cow if she will not average 32 quarts of milk per day, for a month at a time, and that of superior quality; the cow to have no other feed than a good pasture. I could mention a vast number of other cases to show the excellence of Durham Stock for the dairy. The question is well settled in the South part of Ohio.

Yours &c

E. D. SMITH.

Brown City, Ohio, 1811.

Remarks.—We are most willing to be enlightened, and are much obliged to Mr. Smith for the kind suggestion, "that if Mr. Colman would lay aside all prejudice and take the pains to inform himself that I (Mr. E. D. Smith) have, he would be of the same opinion." This is all charming; and Mr. Colman promises that he will do his best to follow his friend Smith's advice, and make some inquiry in regard to this new race of animals about which Mr. Smith speaks, and about which poor Mr. Colman never heard before! Mr. C. cannot promise to lay aside all prejudice because he may be under its influence without being aware of it; but he humbly hopes his chance, being no dealer in cattle, to escape prejudice in this case may be about as fair as that of some of his Ohio friends, who have improved Durham Short Horns to sell.

Mr. Colman has gone very fully into this subject in his Fourth Report on the Agriculture of Massachusetts, in the chapter on Dairy Stock; in which it will be seen that, without having had the honor of receiving Mr. Smith's card, he has virtually accepted his challenge to produce "native stock which equal the Durham Short Horns in the quantity and quality of their milk." This chapter from his report which has just issued from the press, is given at large in the New Genesee Farmer; and it will be seen then by the impartial observer, whether Mr. Colman stands fire or not, or whether he has been completely demolished by the sledge hammer of Mr. Smith.

Mr. Smith's communication is of the same character with many both verbal and written, with which Mr. Colman has been favored; and now let us see how much of it is fact and how much of it, we say it without any disrespect to Mr. Smith, is mere words.

The first fact stated in it then is this, "I have a Durham Heifer two years and a half old that has often given the one quart of milk per day, and that of a

few questions. Were these quarts beer quarts or wine quarts? because it makes a fifth part difference! How was the milk measured, in a quart measure, a gallon measure, or a pail? How often has this cow done this; twice, or a week, or a month? How was she fed at this time? How did Mr. Smith determine the quality of the milk? Did he make butter, and did he ascertain how much butter she would make to a quart of milk or in a week or a month; and if he did why did he not state it? The only test of the good quality of milk is in the butter, which it produces? Again, Mr. Smith says "he has some others almost equal to her." The common saying is that almost is more than half! What does Mr. Smith mean by it? does he mean any thing more than that they are a little more than half as good? and if so, and it he knows what they are, why does he not give us some actual measurement in the case?

The second fact, which Mr. Smith states, is that "one of his neighbors has a full blood cow that he values at three hundred dollars; he offers to give the cow, if she will not average thirty-two quarts of milk per day for a month at a time, and that of a superior quality, and the cow to have no feed excepting that of good pasture." Now all this is just such flummery as we hear every day. Who is this neighbor? Will he give his bond or his word of honor to do this? Does he mean beer quarts or wine quarts? Why does he not try the cow without a bet? He can do it without much trouble. Why does he not see how much butter she will make in a week or a month, and let us know the fact, so that there can be no possibility of mistake or deception? We do not say that the states what is false; we do not know that this cow will not do this and more than this; but we do say, that there will be no difficulty in his getting three hundred dollars for his cow if she will do what is here stated, and if her pedigree is genuine. It is said that Mr. Clay in Kentucky got two thousand dollars for a cow, which certainly did not promise better than this.

Again we should like to ask Mr. Smith, if these extraordinary properties are characteristic of the breed, why we do not have more of these gifted animals among the Short Horns. It is one thing to find extraordinary individuals and another a whole race. Will Mr. Smith inform us likewise, if this is the best race in Great Britain, why the first farmer in England Mr. Coke (Lord Holkham) prefers another race? and in the next place why the Herefords take the prizes at the English Cattle Shows as often as the Durhams?

Now Mr. Smith may be assured, that we have no prejudice against the Durhams. We admire them and mean to do them ample justice. We cannot see any reason why he or our friend Allen should erect their quills and dart their hard looks at us in this manner. We have no Short Horns to sell. A burnt child dreads the fire; and we shall not try again. If Mr. Smith has any valuable and well authenticated facts to communicate, we shall be most happy to receive them. As to "guesses, and almoses, and challenges," we have little regard for them; and have seen in our day as much of cow-jockeying as horse-jockeying.

Fuel.

Farmers who *drive* instead of being *driven* by their business, will be busily occupied in winter in drawing and cutting up their wood for summer use. The great advantage of dry over green wood is generally understood. Green wood usually contains at least one third of water which is evaporated as it becomes seasoned, as is proved by weighing it: this amounts to several barrels of water in

wasted, generally at least one-half. The only case in which green wood can ever be tolerated, is where the draft is so strong up the chimney, as to carry off the greater part of the heat; as in fire-places, and badly constructed stoves. But in stoves where the draft can be closed both above and below the fire to prevent this sweeping of heat up the pipe, the use of well-seasoned wood will be found a matter of great economy.

Small stove-wood, cut up green in winter and placed in an airy wood-house, will be well seasoned by mid-summer; but larger wood requires more time. Large wood, seasoned two or three years, is decidedly better than if seasoned but one year. Those who have not spacious wood-houses, where quantities may be stored, should place their wood for seasoning where it will be most exposed to the heat of the sun, and the action of the winds. And if protected entirely from rain by a covering of boards, it will be much better. The superiority of wood thus secured in seasoning to that corded up in shady woods as is frequently done, is very great. Indeed, the less compact woods, as elm, black ash, and soft maple, are comparatively worthless, unless thus thoroughly dried. J. J. T.

Roads.--Evergreens.--Seckel not ("Seckle") Pear.--Mediterranean Wheat.

(In a letter from Cayuga county.)

In the haste of writing my last letter, I forgot to mention the operation of SCRAPING THE ROADS as soon as they are dry enough after the ground has been soaked, and the ruts become deep. Except THROWING OFF THE LOOSE STONES from the beaten track, there is nothing that improves them so much with the same amount of labor. It is true the effects may not be permanent in rainy weather; but the chances are much in its favor, and the expense is too small in proportion to the benefit, to constitute any valid objection.

When the roads are full of ruts and hubs, which happen more especially in the spring, it is very fatiguing for the team, and straining for loaded carriages to pass. In many districts, the overseers let the traveler work along over such obstructions in the best way he can—and for weeks and months—until the hoof and the wheel batter down the hubs, and gradually fill up the ruts, while one man with a scraper and a yoke of oxen, could make it all smooth throughout the whole district in half a day, or a day at the furthest. Work of this kind is a real labor-saving operation, evincing both intellect and benevolence; and entitling the overseer who directs it, in no slight degree to the respect and regard of the community.

A scraper of this kind is easily constructed of plank 8 or 9 feet long, guarding the edge that breaks the hubs, with a bar of iron.

In stiff clays, a heavy roller to precede the scraper, would render the operation more effectual.

As Noah Webster has not given the word *hub* as we use it, a place in his Dictionary, I copy the following definition for the accommodation of you distant readers, from an article I wrote several years ago.

Hubs—Such parts of a road as have been raised when muddy, by the hoofs of horses or cattle and have become hard by drying or freezing.

The trade in evergreens amongst us, is increasing; and wagon loads from swamps of the neighboring counties, are brought every spring and fall by peddlars who find a ready sale. It is quite a

arance of the country, especially in winter, I make the following suggestions.

Evergreens generally succeed best when set out the spring; and for this reason: a plant in a suppled condition is less hardy than when it is in perfect health. Besides the leaves of evergreens sustain their sensibility throughout the year; and if the roots are much mutilated, or become dry in autumn, they must stand six months without nourishment.* Such a fast is too much for them. Even deciduous shrubs when taken from the woods at that season, not unfrequently die down to the root. These however, may 'revive in spring, sending up new stems; but no such resuscitation awaits the pine or the spruce. When their leaves fade and drop off, there is no hope of recovery.

But when an evergreen is transplanted in the spring, it has time to recover from its crippled state, before the rough hand of winter assails it. Without delay it begins to acquire new roots and nourishment; and takes possession of the soil before any adverse season approaches.

The roots of evergreens generally incline to spread near the surface; and in this they should be indulged, and not loaded heavily with earth. To secure the trees against wind, they should be well fastened to good stakes firmly driven into the ground.

To compensate them for the rich muck and moisture of the swamp, give them liberal supplies of chip-dirt, mixing it well with the soil; and water them moderately in dry weather. A covering of leaves or litter over the roots would be useful to prevent the earth from caking or hardening, to protect the shallow roots from the heat, and to assist in retaining the moisture.

Evergreens from the swamps or woods have to acquire new roots before they can flourish in arable land. After the first year, they are generally out of danger from transplanting; but two or three years elapse before they send up vigorous shoots. On this account, they are much more likely to grow from the nursery than the swamp.

The most beautiful of our native evergreens, is the Balsam Fir. The White Pine, White Spruce, Red Spruce, and White Cedar of the swamps, are also fine; and the Hemlock and Red Cedar are likewise deserving of a place in the door-yard or shrubbery.

Pedlars of evergreens are not always to be trusted. Last fall, one of this enterprising class, called on a friend of mine, and offered to sell him trees of a rare and extraordinary kind. He had purchased the seed on ship board, and raised them in a nursery of his own in a distant county. They were beautiful evergreens, bearing red berries! What an acquisition! My friend bought some, but learned in a few days they were the Red Spruce—probably from a swamp in Tompkins or Cortland county!

Lawrence Stokell was a merchant of Philadelphia, distinguished for his wealth, public spirit, and benevolence; and always spelled his name in this manner. One of the streets of that city is dedicated to his memory. The original pear tree, bearing this name, was found on his farm about one mile above the confluence of the Delaware and Schuylkill rivers. It was still standing there eight or ten years ago, though somewhat decayed on one side. All pomologists who are averse to having their

names twisted out of shape, ought to assist us in resisting such innovations.

I was conversing lately with a friend of mine from the neighborhood of Philadelphia, in regard to the *Mediterranean Wheat*, which he considered a very valuable kind; and we concluded that the writer* in the Farmer's Cabinet who thought it so inferior, must have meant some other sort. The editor of that paper ought to be competent to settle such disputes. He is "inclined to believe" it however, "a spring wheat which ripens in three months from the time of sowing"; while my correspondents represent it as a winter wheat; and one of them remarks that it bears to be sowed "early" in autumn.

Since my former communication relative to this wheat was written, I have received a letter from a (third) correspondent, living remote from the others, and dated near Moore Hall, in Schuylkill township, Chester county. It contained the following postscript:

"Have you the *Mediterranean Wheat*? If not, get it."

Ploughing Matches.

I was gratified to see in your last number, the just and excellent remarks of Myron Adams, on these matches—where the man wins the prize, usually, who drives his horses most severely. In addition to what is there suggested, I would propose that the reward be given to the man whose work most nearly approaches that of a perfect ploughman in his common, every-day operations. The team should move quietly, moderately, steadily; and the furrows should be of uniform width and depth, handsomely turned, and as straight as a mathematical line. The object of these exhibitions, is to improve the art of ploughing; to render it what it should be, for every day work; and not for the purpose of wearing out horses by over driving. It is not the man who scratches over most ground in a given time, but he who does his work best, deserves commendation.

There is one other thing that needs attention on these occasions. The committees who superintend the work, can always find some man in the neighborhood, who has a field, full of stumps, stones, knolls, ditches, and so forth, and who, wishing, if possible, to save his own team the irksome job, would be very glad to have others plough it for him, and therefore offers it for the occasion. Instead of the worst, the best field should be selected; which public spirit, or money, or local pride, if nothing better, certainly ought to accomplish.

And just allow me one remark on the reports of fairs. We have had column after column, containing nothing but the information that A. B. has the fattest hog, and C. D. the finest calf, and E. F. the largest crop of corn, G. H. the heaviest crop of wheat, and I. J. K., &c. the second best of all these; but of what use is this information to the tens of thousands of readers of an agricultural paper? Five readers out of twenty thousand may know the individual named: and here the value of the report terminates. How large the crops were, or how they were raised, or what the size, quality, and breed of the animals were, we are wholly unable to determine. But if the amount of the product and the means by which it was obtained, were given, all would be more or less benefited.

J. J. T.

Laying out Farms.

There is one department of agriculture very much neglected,—that is the laying out of farms

*See New Gen. Far. Vol. 2, page 172.

for convenience and economy. Much attention is given to improvements in stock, in implements, in modes of culture, and in the construction of farm buildings, all of which are of the very first importance; but the proper disposition of the different fields of a farm, for the sake of economy in fencing, for convenience of access, and for a full command of pasture and protection of crops, has hardly received a word of attention in any of our agricultural journals.

Many farmers suppose that this business may be very quickly disposed of; and that a few minutes, or a few hours at most, will enable any man to plan the arrangement of his fields about right. But this is a great error.

Even where the farm is as simple in its shape and situation as can possibly be, which is that of a square or parallelogram, in a level country—there are many things to be considered in laying it out. In the first place, we all know that the fencing of a moderately sized farm costs generally, at least several hundred dollars; and it is very desirable to do it well, so as to protect every part of it, and at the same time use as little material as we can. To accomplish this, much will depend on the shape of the fields. A certain amount of material will enclose more land in the shape of a square, than in any other form.* Hence it is important that all the fields should be nearly square. The disposition of the lanes which lead to the field, is a matter of importance, in order that they be not of unnecessary length, and consequently require an unnecessary quantity of fencing, and occupy more land than is absolutely essential. But there are other considerations which may materially affect these rules.

For instance, it is exceedingly desirable that land of similar quality may be in one enclosure. Some may be naturally too wet for any thing but meadow or pasture; some portions of the farm may be much lighter than others, and susceptible of ploughing while others are not; and some may be sterile, and need all that can be done by manuring and ploughing-in green crops. All these kinds of soil should, as far as practicable, be enclosed, each in its separate boundary. The situation of surface drains, which are needed on all farms, and which should form a part of the boundary of field, may affect their shape. Facilities for irrigation, a practice of great importance in our comparatively dry climate, and greatly neglected, should also be taken into consideration. Convenience for watering cattle, and other minor particulars, are not to be forgotten. All of these should have their influence in laying out a farm, even if that farm be a parallelogram in a level country.

But in hilly countries, where farms are often of irregular shape, and where it is impossible that fields can be square, still more thought is required in their subdivision, which will perhaps require years of experience to perfect. But when fixed fences are once made, it is no easy matter to remove them, and hence it becomes important to ascertain beforehand where they should be. Much trouble may thus be saved, by a judicious weighing of advantages and difficulties. For instance, a farm road, which will be much used for heavy loads, should be hard, level, and short; and the shape of fields may conform considerably to these requisitions. But a road of little importance, should not interfere with the shape of fields. So with other particulars.

In a future number, I propose to carry out these hints somewhat into detail, and perhaps give a few plans in illustration.

J. J. T.

*A circle and hexagon are exceptions in this rule, but their introduction into plans of farms would be impracticable, at least in most instances.

*That is, without nourishment drawn through the proper organs—the spongioles. Moisture would be imbibed by the bark, as it would be by the skin of a bather; but this is insufficient to nourish the leaves, except in the most favorable seasons.

ROCHESTER, FEBRUARY, 1842.

Monroe Agricultural Society, Notice.

The annual meeting of this Society will be held at the Arcade House, Rochester, on Saturday the 19th day of Feb. inst., at 1 o'clock; for the election of officers and the transaction of other important business—a general attendance is desired.

H. W. WARD, Sec.

We invite the particular attention of the Farmers to the above notice. Matters of interest are likely to be presented to the meeting and we hope every member will be in his place.

TO CORRESPONDENTS.

We respectfully solicit the continued aid of those persons, who have heretofore enriched the columns of the New Genesee Farmer with their communications. We solicit at the same time the correspondence of all disposed to aid us, to whom our paper is sent. To those who thus favor us and desire it we shall be happy to send the paper free of charge. We should be glad to receive communications and propositions from persons willing to become regular correspondents for the New Genesee Farmer upon pecuniary compensation, engaging upon our part if the communications are what we want, we will pay for them as liberally as the circumstances of our paper admit. We have no pretensions to making our paper the best agricultural paper in the country; but we promise to make it as good as our ability and means will enable us to do. We shall not be sorry if others beat us. The competition will do good. Let us have a fair field. The success of a paper or a man is not to be considered in comparison with the advancement of the great cause of an Improved Husbandry. If we are disunited at the first heat, we will try again. We will not be quarrelsome if we come out head and head. If the steed fails because the jockey does not know how to ride or to manage his horse, we think so far as we know the lad, he will at once dismount; but if not let him be thrown. The judges we have no doubt will see fair play.

To the LADIES, or as good John Q. Adams would say, to the women, which we like much better: Why should not you help us? In the present number we have a letter from a female correspondent. We shall welcome as many as may be sent us, unless they should happen to contain a gentle offer of a nameless kind, which, whether willing or unwilling, we shall be compelled to decline for the simple reason that we are provided for. Our co-laborer however, of whom we have not a print at hand or we should be tempted to give it in these days of ornamental typography, is still in an unfortunate bescausate condition, and all such letters, we shall hand over to him; with what success we cannot predict.

We should be glad to hear from our female friends on the subjects of gardening, horticulture, silk-raising, bee management, poultry management, house-keeping, house-hold manufactures, the management of children or the management of husbands, and any thing which comes within their beneficent province of mending the manners, or mending the hearts, or mending the morals. They are the salt of the social body, without which it would soon dissolve in corruption.

Explanation.—The editor hopes it cannot be necessary to say that the January number was made up without his agency or knowledge, or he could not have admitted on the last page some kind notices of himself, which his friend Batcham, with the best intentions inserted.

For the New Genesee Farmer.

Feeding Trough and Rack for Sheep.

MR. BATCHAM—I have seen several differently constructed Sheep Racks recommended in the agricultural papers, and have tried several. I have found some objection to all that I have seen. In this vicinity, where we do not feed exclusively on hay, but make use of straw, chaff, roots and bran, it is important that we have racks and troughs in which we can feed the different kinds of food in the same trough and rack. I used for several years the common board trough for feeding chaff, roots, and bran, but they were not suited to straw or hay. Last winter I attempted to improve on my board trough by attaching a rack to it; and so combined I find it the most convenient that I have seen. It is cheap and light, so that it is easily removed; and if they are kept under cover in the season when they are not in use, they will last many years.

Description of the Rack Trough.—Take pieces of timber three inches square and twenty-two inches long, and halve them together crosswise, so that the upper end will be twenty two inches apart. Make three pair of them for one trough, one for each end and one for the middle. Put into them two boards 12 feet long, 1½ inch thick; one 12 and the other 13 inches wide; put in the widest first and secure them fast to the timbers with nails and a board at each end, and you have the trough. Then bore holes one and one fourth inch in diameter, eight inches apart, and one inch from the outer edge of the board for the rack; make the sticks for the rack three feet long. I have used cedar for the rack sticks; they are sufficiently strong and are easily made. Split them one and a half inch square, take off the corners, insert one end in the holes and on the upper end put a board three inches wide with holes corresponding with the bottom, and you have a rack and trough complete. Pious feeding sheep, will find such a rack trough well worth their notice, if they feed hay and grain only.

The readers of the Farmer have reason to congratulate themselves on the arrangements that you have made in the editorial department. Mr. Colman is favorably known as an agricultural writer, and his locating himself in the Genesee Valley will open to him a new field for his usefulness. While in the agricultural survey of Massachusetts he must have laid in a valuable stock of information, from which he may frequently draw, to the interest of the readers of the Farmer, and through its columns they can interchange opinions with him. And it is to be expected that he will frequently test the hospitalities of the farmers of the Genesee Valley, and that he may frequently call on the Wheatland farmers, where he will receive a hearty welcome.

R. HARMON, Jr.

Wheatland, Dec., 1841.

Remarks on the above.—We feel obliged by the communication of our respected correspondent, and hope often to hear from him. We think his sheep rack, on some accounts, well contrived; but not the best mode. We object to all racks in feeding sheep or horses. The hay which is put into them protrudes itself between the stakes and is liable to be drawn out and trodden under feet. The position in which it obliges a horse to put his head, is an unnatural one, and must be painful one, unless, like the skinned eels, they have ceased to feel it by getting used to it. This objection does not apply so strongly to sheep; but

but they are equally liable to waste the hay from racks. Another objection we have to it is, that if the sheep feed on both sides of it, as we suppose is intended their heads are brought too near together; and though in general peaceably inclined, we cannot entirely depend either upon their natural temperment or their good principles, to feed quietly when placed in so close contact. We do not think, in the next place that the rack proposed is made with so little expense and trouble as our friend suggests. We do not mean however, to object to his plan without offering to the judgment of the farmers, what we deem a better one. It may not be however; but we have tried various kinds of hay-severs and mangers, and for sheep we prefer this to any other. We give it with the plan and description from our Fourth Report on the Agriculture of Massachusetts. It will be seen that by placing two pieces of board like an inverted trough, or like the saddle boards on the roof of a house, lengthwise of the manger, the bottom of the manger is divided into two troughs; and passing along as we have often done in feeding sheep, with a measure or corn or a basket of cut vegetables, lengthwise of the manger and turning them up on this ridge they are divided nearly equally on each side. The trough is equally favorable to feeding hay; and is easily swept out and kept clean; and if not made too long and heavy, is without difficulty removed from one part of the yard to the other and placed under cover as may be required. The only objection we have heard made to it, is that the wool is liable to be rubbed off of the neck or throat of the sheep. We have not experienced this difficulty, and where sheep are in health their wool is not easily started.

Hay-severs or mangers for feeding neat cattle in the yards, should be mere boxes, too high for them to think of stepping into them, and about five feet square. Four or more cattle can stand and feed at such a box without being able to quarrel by reaching each other from the opposite side, as they are likely to do, where the manger at which they are feeding is narrow.

MANGER FOR SHEEP.—Among the various racks and mangers which I have seen for feeding sheep, there is a simple form which seems preferable to any other: it is as cheaply constructed as any other, and it prevents all waste. In the common form of racks, where they are inclined outward from the bottom upwards, nearly as much hay is drawn out and trodden under foot as is consumed by the sheep.

The manger which is preferable to any other is of such length as to be easily moved by two persons, and is made with four or more upright posts, and with two boards or slats extending the whole distance round its sides and ends. The bottom board on the side may be ten or twelve inches in width; and above that, leaving a space of about a foot or fourteen inches, there may be another board of about six or eight inches in width. The width of the manger or box should be about two feet. It should have a tight bottom, with two pieces of board rising to a point in the centre, say about four or six inches, so as to form a trough on each side, into which when grain or cut vegetables are put, they may be easily reached by the sheep on the side on which they fall. The top may be left open, or a board may be so placed lengthwise in the centre of it as to prevent the sheep from jumping into the manger. I give a rough sketch of an end view of it, though the form is very common.

Cylindric Tiller and Planter.

We publish the account of the Cylindric Tiller and Planter, because we would gladly give encouragement to every attempt and enterprise to abridge, alleviate, or facilitate labor. We know nothing of this machine other than from its advertisement. It would be premature to condemn it; but we should be glad to have some evidence that it had been tried; and were glad to learn that it had been successfully tried. It strikes us at first blush as promising a great deal too much.—If it will pulverise the soil and put it into a condition for planting at the rate at which it professes to move, it will be an immense gain over any common mode of operation; but when in addition to all this, it promises with only one man, and he to ride upon the machine, to do the planting likewise, we confess we should hardly trust our fields to be sowed under such superintendence. We have seen and experimented upon various sowing machines; but we have never yet found any one, excepting the human hand, (the best upon the whole which has as yet been invented though not patented) which did not require constant watching; it would be liable to become clogged; or the dropper would not revolve; or the seed would become too damp and adhesive to run freely; or the bands would become too tight or too loose; or the hopper would become empty sooner than we were apprised of it; and many other incidents and accidents in such cases but too common. For the laborer therefore to be riding at his ease, driving three horses, and perhaps smoking his pipe at the same time, with a planting machine following him, is certainly not the most careful mode of executing this nice and most important operation of husbandry. The advertisement, and especially a part which we have taken the liberty to omit, where the machine is recommended as likely to attract young gentlemen to the pursuit of agriculture from the pleasure and amusement of this operation, is a little too much in the Panacea and Catholicon style, to induce the farmers to throw aside their ploughs in a hurry. We do not, however, condemn the machine; and when it

has been fully and fairly tried; and even half its professed merits established, we shall warmly and honestly recommend it. In the mean time we engage to keep ourselves cool; and "hearken to the evidence."

From the N. Y. Mechanic.

The Cylindric Tiller and Planter is the invention of Messrs. R. Porter and J. F. Scheerhorn, and as its name imports is designed for agricultural purposes; and in lands free from stumps and stones, is calculated to supersede the use of the Plough. It is composed of a strong wooden frame of about eight by eight and a half feet square, and in the forward part of which is fixed a cylinder, three feet in diameter, and about seven feet long, with twelve rows of sharp iron teeth, nine inches long, and twelve in a row. In the rear of the cylinder is placed a shaft, to which is affixed eleven spiders of equal length with the teeth of the cylinder. In the rear of the spiders is placed a corn or cotton planter, and both the spiders and planters are connected by wheels and bands with the main cylinder.

This machine is so arranged that when put in motion, as the cylinder rolls forward, each tooth will enter the earth, at the precise point, that in the progress of the cylinder, will come in contact therewith at the point from which the tooth projects. Each row of teeth, as soon as they have penetrated the earth to their full length, begin to break up and raise a piece of the earth or make a furrow about nine inches wide, six feet long and six inches deep. This, as it is elevated, comes directly in contact with the spiders, which as they revolve break it to pieces and pulverize it. After this comes in play the corn or cotton planter, which first opens a furrow to receive the seed, which is then dropped from the hopper, and immediately after covered.

The corn and cotton planter can be removed at pleasure, and a drill substituted in its place to plant wheat, rice, or any small grains—and by removing it entirely, the cylinder and spider is well calculated to break up and prepare the soil for any crops—sugar, tobacco, or root crops.

It is estimated, that with the Cylindric Tiller and Planter one hand, with a team of three good horses, will be able to prepare for planting and seeding, (and at the same time actually plant or seed,) twenty acres in a day, of corn, cotton, wheat, rice, or other grain. This calculation is based on the

supposition, that the team moves at the rate of about two miles an hour, and reckoning the usual time that a farmer works when engaged in ploughing, which is over twelve hours a day. This is more than ten ploughmen, with ten teams can do, with the best of ploughs in the same time. This may perhaps appear incredible, that the Cylindric Tiller should possess such great advantage over the common plough; but if we consider the immense friction of the plough on every part where it comes in contact with the earth, besides the direct resistance it meets with, by the condensation of the earth against the plough share, from the time that it begins to raise the earth from the furrow, until it throws it over, and the dead pull by which the whole has to be effected, it must be acknowledged that no machine has ever been invented, that requires so much power applied to it, to move a given weight, and works to so great disadvantage, as the plough. The Cylindric Tiller and Planter has also considerable friction, and requires some power in pressing and drawing one row of teeth in the ground, while it is elevating the earth with another, and breaking it to pieces with the spiders; yet it must be remembered that much of this friction in pressing the teeth into the ground, is overcome by the weight of the machine itself, and the leverage which the team has in revolving or rolling over the cylinder, gives it a vast advantage over the common plough, in raising the earth, and performing all its operations—and if a man can with ease force his spade into the ground nine inches, and raise a spade-full of earth, and turn it over,—and the power of one horse is equal to six men, it does not appear that it would require a very great effort for three horses with this machine, to turn over about twice nine spade-fulls, allowing the spade to be eight inches wide.

This machine will be of great advantage especially on the prairies of the west and the plains of the south, in which grain, cotton and sugar, are the great staple produce of the country. It can be made and kept in order by a common Carpenter and Blacksmith, and purchased for what one surplus team and plough would sell for.

Information respecting the Cylindric Tiller, may be obtained from R. Porter, City of New York, or Mr. B. F. Scheerhorn, Delphi, Carroll County Ia. Editors of papers who take an interest in agricultural improvements, are requested to give the above a notice in their papers.

Meeting of the New York State Agricultural Society at Albany Jan. 18th and 19th, 1842.

The New York State Agricultural Society held its annual meeting in Albany on Wednesday and Thursday, the 18th and 19th inst. The Executive committee met for the transaction of business on Tuesday, in the hall of the Young Men's Association. The attendance was large, numbering from 150 to 200 of the enlightened and strong friends of agriculture from different parts of the State. The Chair was taken by Joel B. Nott, President of the Society, and a large number of the County Societies were represented by their Presidents or by special delegates.

The room was hung round with well executed portraits of superior animals, chiefly of the Improved Durham Short Horns, and improved breeds of sheep, a large portion of them being portraits of animals belonging to E. P. Prentice, Treasurer of the Society, C. N. Bement of Albany, and other members of the Society. To an unpriced eye, accustomed to look only at the common herds and animals which are seen in our farm yards and pastures, these pictures would have been pronounced the mere fictions of the painter's imagination; but an actual examination of the animals themselves left no reason to question his fidelity to truth and nature. The pictures seemed as handsome as the painter's art could make them; and the animals were quite as handsome as the pictures.

The President's table was at the same time covered with several valuable pieces of silver plate, a tea-pot of silver, and several cans and tumblers, which were to be bestowed on the fortunate competitors for prizes at the late Fair at Syracuse.

In a neighboring room was a large and handsome show of dairy products, presented for the premiums of the Society, and some samples of vegetable and grain crops.

Some skeins of silk likewise, produced and manufactured at the Auburn State Prison, were presented for the examination of the committee.

The reports of the several committees having been made, the premiums were duly awarded and presented, some in plate and others in cash. These reports and awards will hereafter be duly given. At present not being familiar with the names either of the several committees or competitors, we cannot trust our memory to report them. We can only say we felt a little envy of the gentlemen who carried out of the room the brilliant trophies of their honorable success; and could not but imagine the charming and complimentary reception they might expect at their own domiciles, with such dazzling bribes in their hands.

There was exhibited likewise, a most excellent and beautiful article of household manufacture, in a lady's bonnet, made of Manila grass. Its fineness was not surpassed by anything of the kind we have ever seen. The Society voted to the fair artist a complimentary gratuity of five dollars. This was certainly well. One gentleman, a bachelor we believe, and there was certainly strong internal evidence of the fact, commended the article, among other excellencies for its durability. "It was not a flimsy thing which would bear the wear only of a season, but was likely to endure for years." Just as though this would recommend it to our fair city ladies, or even to the farmers' daughters of one of our most secluded hamlets. Alas! how little does he know of female taste, when unless it goes by Harden's express, it is not certain that you could send a bonnet from New York to Buffalo before the fashion would be changed. One would suppose that this gentleman had just descended from one of the mountainous cantons in Switzerland, where the same woolen tiara and the same quilted petticoat go down to daughters and grand daughters,

and a pair of wooden-shoes lasts through several generations.

The report of the Treasurer was received with much applause, announcing as it did, so different a condition of things from most other treasuries of the day, in stating that the Society had remaining in its coffers, after all its debt were paid, a balance of 823 dollars for future operations. In this day of universal emptiness, when there is scarcely a bar-keeper or toll-gatherer, who does not report embezzlement, or over-issues, or suspension of payments, or necessity of a loan, or some new exchequer plan, or ask leave to issue treasury notes, this result produced such a shock as the assembly did not recover from for some time. For ourselves, we could only wonder where this green band of a treasurer could have lived in these days of financial discovery and improvement, and pray that no one would think of putting him into public life lest his good morals might be endangered. The great security is however, that the kind of tact, which he displayed, is not at all in demand just now. Promotion with such a man is well nigh hopeless.

The Report of the Corresponding Secretary was read, announcing that, in reply to his applications, he had received valuable communications from various distinguished gentlemen at home and abroad, for the volume of Transactions of the Society, now in a course of preparation for the press. His correspondence had been extensive and had met with a hearty response. Among others he had received a valuable communication from the Philippine Isles.

On motion of Mr. Randall of Cortland, a committee to nominate officers was raised; and it was devolved on this committee to designate the time and place for holding the next annual state fair.

On the report of the committee, the following gentlemen were elected officers for the ensuing year.

President.

JAS. S. WADSWORTH, of Livingston.

Vice Presidents.

- 1st dis. JEREMIAH JOHNSON, Kings.
- 2d do ROBERT DENNISON, Orange.
- 3d do ANTHONY VAN BERGEN, Green.
- 4th do JOHN SAVAGE, Washington.
- 5th do ORVILLE HUNGERFORD, Jefferson.
- 6th do GEO. I. PUMPELTY, Tioga.
- 7th do JOHN M. SHERWOOD, Cayuga.
- 8th do L. B. LANGWORTHY, Monroe.
- II. S. RANDALL, Cortland, Cor. Sec.
- LUTHER TUCKER, Albany, Rec. Sec.
- EZRA P. PRENTICE, Albany, Treasurer.

Executive Committee.

Alexander Walsh, George Vail, Henry D. Grove, Rensselaer; John M'D. McIntyre, and James L'Amoreux, Albany.

The committee recommended that the annual state fair be held at Albany on the 25th and 29th September next. This proposition was subsequently modified so as to read Albany or its vicinity.

On motion of Mr. Johnson of Oneida, a dynamometer was directed to be purchased, and it was recommended that the county societies each procure a similar one.

On motion of Mr. Clarke, the executive committee was directed to offer premiums of gold medals, or plate, or their equivalent in money, for the best essay on subjects to be selected by them.

On motion of Mr. Morrell, of Tompkins, the thanks of the society were voted to the Young Men's Association, for the use of their rooms.

The thanks of the society were voted to the officers of last year, and the meeting adjourned, to meet at the capital at 7 o'clock, P. M.

The Society having accomplished its business, met at the Capitol at 7 o'clock, where an address was delivered by Mr. Nott, the President of

the Society. The address was excellent in manner and matter, and received with universal satisfaction. We shall attempt a brief sketch of it, but it must be very imperfect excepting as concerns its topics. A copy was requested for publication; and in due time we hope to lay it before our readers from the author's own hand.

Many of the members of the Society and friends of Agriculture, in the evening, partook of an elegant supper at the City Hotel. The company were honored by the presence of the Governor and other guests. The evening passed off with much hilarity; and presented a beautiful demonstration, that when the benevolent and patriotic affections are kindled in a generous and noble cause, as much healthful heat and exhilaration can be manufactured out of the crystal spring of pure water as ever flowed from the colored waters of Madeira or the sparkling and gushing fountains of Burgundy, and this too, without leaving any scorching, or cinders, or smutiness behind.

The meeting was addressed in an effective, appropriate and agreeable manner by the President, the Governor, Gen. Leland, Alderman Joy of Albany, Judge Hungerford, Mr. Walsh, and other gentlemen, and broke up seasonably in good fellowship, and with a more quickened zeal and a more fixed determination in the great objects of their association. So mote it be!

But where are the broken glasses, and the up-turned tables, and the smutty toasts, and the ribald songs, and the profane jests, and the vile taunts, and the fiery resentments, and the folly and the emptiness, and the leadings home and the disturbed households, and the violent headaches, and the bitter mortifications, and the quickened appetites for further and more degrading excesses, which constituted once the usual accompaniments and appendix of such evening entertainments. Thank God, they are among the things that were! They will soon be looked upon only as the fictions of romance; and gentlemen will feel that the very mention of them, is an imputation upon their honor.

Mr. Nott's Address at the Meeting of the State Agricultural Society of New York in the Capitol at Albany, on Thursday evening, 19th January, 1842.

We subjoin an imperfect report of this excellent address from our own imperfect and hasty notes taken at the time, under many disadvantages. We have sought only to give the topics and the sentiments, but we may have been so unfortunate as even to have mistaken or omitted these. In this naked condition Mr. Nott may not be able to recognize his own offspring; and we shall not charge it upon him if he does not choose to acknowledge it. Presently we may be so fortunate as to receive it in its full dress from his own brilliant wardrobe and perfumed toilet.

Mr. Nott commenced his address by stating that the First Meeting of the Agricultural Society of the State of New York awakened a strong interest and excited sanguine hopes of its ultimate success. But year after year, a small but gallant band of the friends of improved agriculture had nothing to cheer them. They were compelled to struggle with many difficulties; but like chosen men placed upon the storm hope they were determined to triumph. There is a moral power in such a resolution, before which, ordinary obstacles at once retire. Their efforts have been successful. They are cheered with an actual and glorious triumph; and their path onward, is brightened with the confident hope of continued and extended successes. At one time they had neither the aid of the government nor the inspiring favor of the people. But circumstances have changed. The Legislature have extended a helping hand; and the people urge them onward by acclamation.

The great Fair at Syracuse, held in the last autumn,

was an unusual but a successful experiment. It much exceeded the expectations of its friends, in the animals which filled its pens, in the improved implements of husbandry exhibited for the inspection of farmers, and especially in the large collection of intelligent men, practical tillers of the soil, enlightened friends of agricultural improvement, collected there from all parts of the State, and in the presence of distinguished friends of agriculture from other parts of the country. Much credit is due to the moral courage of the gentlemen who undertook and so nobly effected this pioneer movement; much to the Government, who patronised the enterprise, and much to those high-minded individuals, who, in determining the place of meeting, yielded all personal and local claims; and to those friends of the cause in the vicinity, who contributed efficient aid to the successful accomplishment of the project. Every event which serves to elevate the condition of the industrial classes; every circumstance which strengthens our attachment to the soil; whatever contributes to increase and unfold the means of human subsistence and comfort, are of great moment. Shall a career commenced under such favorable auspices proceed? or shall it come to an unfavorable termination?

The first Agricultural Society in the State was formed by the patriots of the Revolution. They were wise men. Where have been found men more wise? We may be unconscious of our obligations, but we owe them a heavy debt of gratitude. The history of their efforts to promote the improvement of the agriculture of the State, forms a brilliant chapter in its history. The second Agricultural Society, formed in 1818, was not much better known, but its labors were highly valuable and important. They have passed away. Shall the Society of 1841 follow in their train? Our aim should be to render our labors not only brilliant but abiding. It remains to be seen how far the standing of its members will give it a moral influence. Our associates are in general from private life. As yet none of the Government have lent their aid to us; few of our legislators; and comparatively none from the learned professions.

Must agricultural societies fail? Is there within them an inherent principle of dissolution? Other societies flourish from age to age. Why should agricultural societies be debared from a like immortality? Are we earth-born or character? Something must depend upon the character of the people among whom these societies are established. If the people cannot be made to take an interest in them, and to perceive their utility and the advantages to accrue from them, they must decline. In some places they have been sustained. The seed has not always perished in the ground. The Highland Society of Scotland has continued to flourish for a long period. The Berkshire Society in Massachusetts wears a green old age. The people of the districts in which these societies exist, are remarkable for their agricultural thrift and skill. Is the duration of these societies attributable to some peculiar excellence in their management?

Our societies have never reached the multitude. The present English Agricultural Society is a brilliant institution, formed on the model of the Highland Society of Scotland. Shall we concede to Berkshire superiority of intellect? We have not failed through deficiency of knowledge. The eminent success of these pattern societies is worthy of observation. Agricultural fairs have become interwoven with the habits and customs of the people. Men of business have looked forward to them to favor their operations. Men of leisure have expected their coming as a charming holiday and a delightful recreation. Age seeks them to renew the recollection of youthful labors and sports. Youth welcomes them with all its natural enthusiasm. The ploughman alone in his work, pleases

his imagination with the hope of a premium. The hind anticipates with an honest pride, the applauded exhibition of his cattle. Our path is indicated by experience. Men, from whom better things were to have been expected, have hitherto withheld their aid. The success of the Cattle Show at Syracuse has compelled an acknowledgment of their error. We must hold an annual Cattle Show. We must augment the amount and the number of our premiums. We must open the competition to all classes; the poor as well as the rich; the humble woman, who may choose to contend for your prizes by any exhibition of her household or rural skill and industry, as well as the rich capitalist; the humble laborer, as well as the great proprietor. We must encourage and stimulate every branch of domestic and rural labor.

Our treasury is not empty but our purposes require at least a thousand subscribers. Our list does not contain half that number, and of this half, not more than two thirds pay their annual assessment. It is supposed that if the conditions of membership were enhanced, the funds of the society would be increased; but the terms should never be beyond the ability of the humble laborer.

One officer of the Society should be a salaried officer, on whom many active duties would necessarily devolve. It deserves inquiry, what would be the effect of the establishment of a Board of Agriculture, the members of which should be expected to pay liberally to the funds of the society. There are men among us willing to serve every public cause. The temperance cause does not stand in need of bold advocates and indefatigable leaders. The Young Men's Association, whose objects are mutual improvement and the diffusion of knowledge, find those who are prompt to lend their aid. Such men should be made acquainted with the generous and public-spirited objects of our Society.

In all our villages, literary and scientific associations have been established. They have enlisted the best talents to be found, in the advancement of their objects. Men of all descriptions, philosophers and poets have brought their contributions to these common fountains of instruction. This constitutes a popular university and renders knowledge every where accessible. It is to be feared that the farmer is behind hand; he does not do justice to himself, and other classes distance him in the race of improvement. We should seek especially to secure to the farmers opportunities and means for becoming acquainted with the principles of their own art.

If a board of agriculture should be established, its beneficial influences would be felt in the remotest valley of the state. Educated young men on leaving college find the learned professions crowded. They obtain only a very limited success; and must struggle with many difficulties in order to make their way. We find young men of all political creeds, ready to abandon their pursuits and seek political preferment. This is a thorny path. To those who make political success a matter of profit or loss, we can point out a field where gain is far more certain. We should reject the notion that knowledge and education are thrown away in farming. If the farmer is desirous of taking rank with the highest in the community, it will not be difficult to accomplish this honorable ambition; and education will give dignity to his calling.

It is not inconsistent with the character of a farmer to be a man of taste. "Man made the town, God made the country." There is no reason why ornamental farming should not be cultivated; and it is not inconsistent with the highest regard to profit, to embellish our grounds and our habitations, and to render our homes as beautiful as a simple and most refined taste can make them. If these high accomplishments of taste and mental cultivation can render no

service and are unfitting to an improved agriculture, then, as Cheever remarks, God cannot appear as an architect of practical wisdom, since his sky and earth are every where robed in beauty. Every object around discloses in its exquisite formation, the goodness and glory of God; and the meaneat flower gives thoughts too deep for utterance.

The agricultural life may be incompatible with the highest pursuits of science; these require the exclusive devotion of the life; for in this, as in all other cases, he who would woo the muses must bid farewell to professional eminence. But there are many practical farmers as there are practical men in all other departments of life, who have distinguished themselves in knowledge and literature. Thompson and Cowper have sung the charms of rural life. How powerfully are rural pursuits adapted to awaken a strong interest. The pastoral life has been always deemed favorable to high and religious conceptions. One shepherd has poured forth his soul in the holiest and loftiest strains, "When I consider the heavens the work of thy fingers, the sun and moon, which thou hast ordained, what is man that thou art mindful of him, and the son of man that thou visitest him."

Agriculture presents no impediment to the cultivation of science and literature. The pursuit of agriculture has been too often deemed degrading. Johnson, in a tone of disdain, says of one "that his talk was of beehives." This was unworthy of him, and inconsistent with his notions of utility. The scale of rank, by which the pursuits of life have been graduated, was formed in times of war and in ages of ignorance. The pursuits of men no longer lead to war; but to fields covered with the gifts of Ceres and Pomona.

We should seek to disabuse the public mind of these unworthy prejudices. We should raise our profession to its proper dignity; nor allow a lawyer or merchant to think that he loses caste by becoming a farmer. There are impediments to so desirable a result. In other pursuits men are stimulated by the rewards of applause or fame. The successful farmer is beyond the reach of these motives. He gains no fame; there are no offices of honor exclusively for him. A Board of Agriculture should occupy the same position to the agricultural societies as the Board of Regents to the schools and places of education. These suggestions should have weight with those who discuss this question. The Society, as already observed, should have a paid agent. It should have agricultural rooms—it should lay the foundation of an agricultural museum and library. The foreign press is teeming with agricultural publications of an expensive character, which might prove of essential service to American Agriculture, but which are beyond the reach of most individual farmers. The American mechanic has done much by inventions for facilitating or improving labor, simple in their construction and excellent in their workmanship. Models of ingenious or improved agricultural implements, would furnish a store-house of invaluable instruction and benefit. Agricultural science and agricultural literature are sneered at by men, who suppose that a volume of veterinary medicine constitutes the whole of an agricultural library. The Edinburgh Quarterly Agricultural Review, one of the most able publications of the age, few men are competent to read understandingly; and few are capable of contributing an article worthy of its pages. It is singular that science should be deemed useless in agriculture, when it has availed so much in all other arts.

The union of science with art has given to it a gigantic power and consummate skill. It has been displayed in preparing dyes and in weaving a web of exquisite tissue. Art under the guidance of science presses forward into the ocean of discovery. If we would gauge the improvements of the arts in Europe,

we must compare their condition with the condition of the arts in China. Europeans found on their first visit to China, a state of high improvement in the arts. But while Europe has advanced with a most rapid improvement, China has made no progress since the Cape of Good Hope was doubled by Vasco da Gama.

It is said that science has not yet done for Agriculture all she ought. It is because science has not as yet had it in its power to do more. We may expect the best results from agricultural chemistry. Its sun has just risen. Its level beams promise great advantages. The labors of Liebig encourage the strongest hopes.

The agricultural movements already made, and those which are yet to be made, are not in advance of what should be. The progress of the United States in other things must contribute to the advancement of agriculture. The progress of agriculture is a test of the moral progress of society. In the savage state, there is no agriculture. In the semi-barbarous there is little. If you will show us fields cultivated and adorned, we will show you a people intelligent and refined. War is most unfriendly to agriculture, which is eminently one of the arts of peace. It was said that France had no literature; she had only books on war. Peace has remedied this defect. The same may be said of us. We have farmers but no agriculture. We trust a few years will place us, in this matter, in an advanced rank. If peace is preserved, agriculture must continue to advance among us. Why should agriculture remain stationary with us? The bible, that book of wisdom, speaks of a high state of agriculture as consequent upon a condition of peace. Should the prediction of the prophet be realized, the desert place will be glad, and the wilderness will blossom like the rose.

Mr. Nott concluded his address with congratulating the Society on the uninterrupted harmony which had prevailed in their meetings; and had shown itself so eminently in the choice of officers; and in the decision respecting the place of the next Fair, a subject on which a division had been feared. This singular unanimity had served only to cement their union. Relying on this union, it should prompt us to be more zealous in laboring in this good cause.

New York State Agricultural Society.

We have received through the politeness of Mr. Tucker, the Recording Secretary, the official report of the competitors for the premiums of the Society. We regret that our limits do not allow of the full insertion of these reports; but in abridging them we have sought to present the most important parts.

The Show of every thing but Butter, was small—Of Butter, twenty lots, from different parts of the State, amounting to over 2,600 lbs. were exhibited. Of Cheese, only six lots were presented, amounting, however, to about 2,900 lbs. There were but three competitors for the premiums on Wheat—five on Oats—two on Indian Corn—two on Buds—four on Potatoes—three on Rata Baga—two on Sugar Beets—one on Carrots.

REPORT ON ROOT CROPS.

The committee found themselves exceedingly embarrassed from the want of the formalities required by the rules of the Society, as well as by the want of evidence of the merits of the different applications.

The committee unanimously reject all applications for premiums on crops that have been estimated by measuring a few roots or other small portion of the acre required by the rules, and which have not the evidence of a correct survey.

Several descriptions of the soil, manure used, labor and other expenses incurred in the results stated, are so imperfect that it was impossible to arrive at the comparative merits of the crops, as to expense—which defects can be remedied another year, by having blank forms made public through the agricultural press—No man should be allowed to compete for premiums, who is not liberal and patriotic enough in the great first cause of national prosperity, to put himself in the way of procuring the necessary information.

Several of the rejected crops are meritorious, if the mere dictum of the growers was proof, and in several cases would have taken the first premiums, had these over-sights been avoided.

The committee think it an act of justice to mention the crop of ruta baga turnips of Mr. P. P. Root of Sweden, Monroe county, reported as producing 1,300 bushels per acre, at 60 lbs. weight per bushel; also the crops of Mr. George Shaffer of Wheatland, Monroe county, which purport to have produced 1,160 bushels of sugar beets and 603 1/2 bushels of carrots per acre, at 60 lbs. per bushel.

The committee award.
For potatoes—to Phineas Hardy of Le Roy, Jefferson co., first premium, for 472 bushels per acre, \$15.
To H. D. Grove of Hoosick, Rensselaer co. second premium, for 440 bushels per acre, \$8.

For ruta baga—to W. B. Ludlow of Claverack, Columbia co., first premium, for 1,625 1/2 bushels per acre, \$15.
To George Shaffer of Wheatland, Monroe co., second premium, for 552 bushels per acre, \$8.
For sugar beets—to S. B. Vail of Mount Laurel Farm, Columbia co., first premium, for 559 bushels per acre, at 60 lbs. per bushel, \$15.

(The Reports of the Committees of the New York State Agricultural Society are in type, but necessarily excluded this month for want of room.)

English and American Agriculture Compared.

MR. EDITOR.—To improve the condition of the cultivators of the soil, and increase the productiveness of the Earth—are objects well worthy the attention of the Philanthropist and Statesman, and it is highly gratifying to see the increasing interest that the ablest and best part of the community are taking in these pursuits. We in this country can and are deriving much benefit from the many and valuable improvements and useful experiments made in England. Yet in introducing them here it is very essential that we should at first test them on a small scale, and prove them thoroughly before we adopt them as our own; for there is so much difference in the situation of the Agriculturists, in the two countries, that what answers the one well, will not do for the other.

The length of the season for agricultural labor, the shortness and mildness of the winter, the low price of labor, the great value of land, and the high price of its products place the English farmer in very different circumstances from us here. Our inquiry must be, how can we cultivate so as to give us the greatest return for our labor.

There it is, how can they increase the products of the soil, regardless of the expense. I am fully aware that the farmers in this section run over too much ground for the labor they have to bestow upon it. Yet I am equally confident if we were to apply the labor and expense per acre that is generally done in England in cultivating, we should not be compensated, the crops would not pay the expense.

Here roots can be cultivated on a small scale to advantage, but never so extensively as in England. Our frequent droughts in summer, which cause so many failures of the crops, the severity of our winters which makes it necessary to secure them all from the frosts and the shortness of our autumns which allows so very little time for that business, all operate against the extensive cultivation of root-crops. How could the farmers in Western New-York manage to raise 50 or 60 acres of roots annually? Yet more than that ratio is profitably and easily cultivated in England. The horses which are considered to answer their purpose best, are not suitable for us; they generally keep two distinct breeds the one for the draft and the other for speed. Here it is very essential that we should unite both properties in the same animal.

Our Sheep husbandry too differs very essentially. There the great value of mutton and low price of wool make carcass the principal object, and the fleece but a minor consideration. Here the fleece is the principal value, and the carcass of little consequence.

There the primary object is to increase the size of the animal and aptness to fatten, here the value of the fleece. Yet I think it would be well for us to unite both properties in our sheep, viz: fleece and mutton.

In the breeding and feeding of neat cattle the difference between the two countries is yet greater. The certainty and ease with which they soon raise abundance of seed and food, the cheapness of labor, the great price of animals and high price of beef, make the heavy and fine breed of Durhams very profitable to the breeder, for it matters not what quantity of succulent food they consume, nor what amount of care they require—if they do but increase their weight the producer is remunerated. But it is very different with the husbandman here. The expense and difficulty in raising our roots compels us to use them sparingly; and the high price of labor will not allow us to bestow on them that care which these heavy and delicate animals require, and if we should, sell these animals for beef at the market value they are generally so low that they would not pay the expense.

The tough and hardy animal that can feed in a dry and often scanty pasture, and live on coarse forage is the most profitable one for us: Our neat stock have to consume our coarse forage and give us something for that which we cannot otherwise take to market.

Although we require hardy animals that can live without much expense. Yet I am confident that many, yes, very many of us do not pay that attention to them which we ought, even for profit, to say nothing of the cruelty of causing them to suffer severely from hunger and cold. The latter we can feed with the food we have to give, and the more comfortable that we can keep our stock the more profitable they will be to us.

Yours respectfully,

Wheatland, Mon. Co. 1842. W. GARBUTT.

We cannot say that we acquiesce in the doctrines above of our respected correspondent to any considerable extent. We have not however in this case time to enter into the wide field into which the discussion of this subject would lead us. At some future occasion, we should be happy to treat the various positions that he assumes. To labor and capital judiciously applied, there is reason to believe that agriculture among us affords a most ample reward and would justify a much more liberal application of them than now prevails, either in the culture of our soil, the production of root crops, or the rearing and maintaining the most improved and best live stock, which can be procured at home or abroad.

In the mean time, we hope some of our intelligent correspondents will enter upon the various important topics suggested in Mr. Garbutt's letter and give us the lessons of their experience and the rich fruits of their wisdom.

Silk Production.

We give with great pleasure the following amounts of silk produced the present season in Manheim, Lancaster Co., Pennsylvania, and communicated by Jno. M. Sumney, who, we hope, will let us hear from him again. Our friend complains that his 'beard' does not work well with the pen; but he may be satisfied that it works so well at the reel. The prospects of the silk culture are constantly growing better. It must succeed, and fully merit all reasonable expectations. We need not be impatient. The multicaulis fog will soon be off; and men will work by the clear light of day.

— Herr has raised and reeled 552 lbs. of Cocons.

Jno. M. Sumney has raised and reeled 524 lbs. of cocoons, and made 100 lbs. of silk.

— Carson has raised and reeled 183 lbs. of cocoons.

John Wisler has raised and reeled 364 lbs. of cocoons.

—Melinger has raised and reeled 150 lbs. of cocoons, and made 12 lbs. of silk.

—Duveth has raised and reeled 190 lbs. of cocoons.

—Shelly & Co. has raised and reeled 172 lbs. cocoons, and made 15½ lbs. of silk.

Many more have raised from 20 to 50 lbs. Mr. Umney adds, that he will warrant his silk to be not equal but much better than the best of Calcutta or alian silk, for quality and texture.

These, together with the facts stated by Dr. Deane, Greenfield, to be given in our next, and the reports from the Auburn penitentiary, with many others that have reached us, speak with an emphasis which must command attention.

The Constitution of Wyoming County Agricultural Society.

Recently formed, provides that their officers shall be located one in each town in the county.

Any person can become a member of this Society, by paying into the Treasury, fifty cents annually, and subscribing to this Constitution.

The funds of the Society shall be appropriated for the encouragement of Agriculture and the Mechanic arts.

OFFICERS OF THE SOCIETY.

For President,

J. C. FERRIS, of Middlebury.

For Vice Presidents,

PETER PATTERSON, Esq., of Perity,

EBENEZER P. BICK, of Sheldon,

C. O. SHEPARD, of China.

For Secretary,

ACOSTUS FRANK, of Warsaw.

For Treasurer,

TRUMAN LEWIS, of Orangeville.

For Directors,

Leverett Peck, of Bennington; Ezra Bishop, of Atca; Milo Warner, of Java; George B. Chase, of Astle; Uriah Johnson, of Covington; Christopher ost, of Gainesville; Daniel Wolcott, of Wetherseld.

The Society holds its annual meeting on the Tuesday succeeding the third Monday in October.

NOTICES OF NEW PUBLICATIONS.

NEW YORK STATE MECHANIC; under the direction of the New York State Mechanics Association. Published at ALBANY—weekly—by J. Munnell & Co.—at \$1.50 per annum—in advance. Eight pages quarto.

CENTRAL NEW YORK FARMER.—A monthly Journal devoted to Agriculture. ROSE, Onondaga Co. N. Y. Johnson and Comstock, Editors. Horace N. Hill, Proprietor. 50 cents per annum. 7 copies for \$3. 16 pages—8 vo.

EASTERN FARMER & JOURNAL OF NEWS.—Semi-monthly. Eight pages folio. Edited by Francis O. Smith. PORTLAND, Me. One dollar per annum.

THE BRITISH AMERICAN CULTIVATOR. TORONTO, Upper Canada. W. G. Edmundson, Editor. J. Eastman and W. G. Edmundson, Proprietors. One dollar per annum including postage. 16 pages qto.

UNITED STATES FARMER AND JOURNAL OF AMERICAN INSTITUTES.—Each number from 32 to 40 large octavo pages, illustrated with engravings. Price two dollars per annum in advance. S. Fleet, editor, assisted by S. Blydenburgh.

We welcome the above new co-laborers to the field and heartily wish them all the success they can desire for themselves. The field is white for the harvest; and the world is wide enough for us all. We have only to express our regret that so recently have they come to hand; and so recently have we ourselves come to hand, that we cannot pay our personal respects to each of them. We may have this pleasure

at some future time. We can say of all of them that their appearance is not fair only but respectable; and that they work wonderfully cheap. We hear continually that presently prices must come down. It is rather difficult to imagine how the prices of agricultural periodicals are to go down any farther. There is no getting below the bottom unless we kneel the bottom out. Where that will bring us, imagination does not venture to predict. The great consolation is that having got down, we need not live in continual fear of a further fall; and flat upon our backs, it can only be said of us that "we are looking up."

We welcome our old friend Fleet back again to the duties of "auld lang syne", and are rejoiced to find him still fleet and sound, wind and limb.

The old Pioneers in the cause, the American Farmer at Baltimore, and its early condutor, The New England Farmer in Boston, preserve a green old age, and hold the even tenor of their way. "Honor to the brave."

The Albany Cultivator is still in its power and undiminished abundance, pouring out its monthly floods of intelligence and wise and judicious counsel; and moving on like the breaking-up team of the prophet with its twelve yoke of oxen.

We are looking daily for a Family Visitor from the Granite Hills, radiating with intelligence far and wide like the reflections in a sunny day from its own White Summit; and burning with a warmth of zeal, which has made many a farmer in that region trickle, who never had his ice melted before.

Boston opens the year with a numerous family, and all healthy and hearty. The Boston Cultivator, under its intelligent editor, H. G. Merriam. The Farmer's Journal, edited with all the industry and experience of S. W. Cole, not unknown in the walks of agriculture. Add to these the Massachusetts Ploughman to which is united the Yankee Farmer, under the veteran Buckminster, full of practical lore, but who, unfortunate man! as we learn from the New England Farmer, does not yet know how to spell his own name, as he is quoted the Massachusetts Ploughman. We shall give him up, if he does not find out his mistake soon.

Then there are the spare hands, the Boston Courier and the Mercantile Journal always ready to lend a helping hand and able to do three days work in one. As to friend Sleeper's sound and useful agricultural address at Wethers, we had prepared a notice of it for this paper but it is necessarily excluded. A man so wide awake to all good interests should be called any thing but *Sleeper*.

We had prepared to speak of other agricultural contemporaries, equally demanding our respect; but it would be idle, for it seems like nought the trees in a thick forest.

Effects of Increased Duties.

We quote an article from the New York Evening Post, depicting in strong colors, the evils which must fall upon the silk manufacturers in Lyons, from the impost by our government of 20 per cent. upon imported silks. There is, it is to be presumed, no exaggerated coloring in this picture. The operatives in the silk manufactures both of France and England, and so also of China, are probably the worst paid and the worst fed of any class of laborers on the continent.

We may, we must, if we are men, feel for them. Every benevolent mind deeply compassionates their condition; but the care of them and their relief he long to their own government and not to us. The situation of few of the manufacturers of any description, on any part of the European continent is better. They are all worked excessively and fare most hardly. The wretchedness in England prevailing among many classes of manufacturers is extreme, and almost past relief. But how to remedy this, or even how to

alleviate it, is difficult to say. This is a problem for the solution of which the heart of the christian philanthropist aches with agony.

If all men were christians, and lived only and fully upon christian principles, if justice and the love of our neighbor prevailed every where, there would be little of this suffering. There would be no occasion for laws other than what would be dictated by every man's own heart and conscience. All penal enactments would be needless, and government would be felt by us only as the great law and power of gravitation are felt by us. But it is not so; and while the reigning spirit of christianity is universal love and universal equity, that of the world is universal selfishness and universal rapacity.

In such a condition of things, it seems idle to talk about free trade. There is not, nor is there likely to be, a civilized nation upon the earth where it exists; and for us to act upon a system of entire freedom of trade, would be only to crush our own industry, to arrest our own improvement, and to expose ourselves as helpless victims to the rapacity of other nations. If other nations were willing to receive the products of our industry without impost, we might then consent to admit theirs upon the same terms; but while they prohibit all competition with their labor, we should seek, in the same way, to protect and encourage ours. The only true independence of an individual or a nation, lies in its power to supply its own wants; and this it should constantly seek to do.

We cannot, in this case, enter upon the great and vexed subject of protection. It would be a charming picture, if we could see all the nations of the world engaged in a free and unrestricted exchange and interchange of their various products. But at present, such a thing can exist only in the benevolent imagination. In the present condition of society, nations are compelled to act upon the defensive, or suffer the bread to be taken from the mouths of their own children. The governments under which these unfortunate people live and suffer, are responsible for a great portion of the misery to which they are reduced; and for that system of bloody tyranny by which they compel them to stifle their complaints, and to die in the agonies of starvation and famine.

Our movement in this matter may produce extreme distress, but it is the duty of their own governments to all-viate their sufferings, or by timely provision prevent them. There is not a single objection to be urged against the encouragement of our own manufactures in this case, but what would apply with equal force to the invention of any kind of art or machinery by which labor may be abridged and transferred, and consequently vast numbers be thrown out of employment. In the end, however, all such improvements redound as much to the benefit of the laboring as of other classes. It would not be difficult to show that the consequences of the free introduction of foreign luxuries, foreign silks, gewgaws, and wines into our country, if it could be examined in all its various influences, has been productive of more suffering or evil in our country, than the imposition of duties upon such articles can produce in Lyons or other manufacturing towns in France or England.

From the N. Y. Evening Post.

The following passage occurs in a letter written at Paris, for the London Examiner:

"Alas! Paris, the greatest and most dangerous agglomeration of artisans is at Lyons, and thence must be much affected by the 20 per cent. increase of duty on silks imported into the United States, half the French export of silks going to that country. If to a thus diminished demand for work, and consequently no hope of a rise in wages, be added dear bread and increased taxation, Lyons may give some trouble during the ensuing year. The trouble, however, is now without danger to the Government, for Louis Philippe has taken care to surround and curb the town of Lyons

with a mass of stupendous fortifications which might defy Babylon itself in a state of insurrection. There is not a woe's garret at Lyons that has not a cannon's month's length down upon it, and all these most extensive fortifications are said, like those of Paris, to have been erected against the foreign enemy! and to dear bread and diminished exports is now to be added the burden of increased taxation.

Such are the relations between the countries in amity with each other, as it is called. The different governments of the world profess for each other, in their public documents, the most friendly sentiments; not a diplomatic note is written from one minister to another, that is not as full of goodwill as a Moravian sermon; yet their whole conduct towards each other is but a selfish struggle for advantages, without regard to the sufferings it may cause. In the midst of these mutual professions of just ice, kindness, and benevolence, one nation will, without any sort of scruple, adopt a measure which levels a deadly blow at the industry of another, and dooms a large portion of its hard-working inhabitants, the most helpless, as well as the most meritorious class, to starvation.

This is done with the utmost coldness and unconcern; nay it is made a matter of boast, if, in consequence of starvation of a few thousands in another country, it is thought that a remote possibility exists of enriching a few hundreds at home, and he who should speak of this as a wrong, or express any sympathy for those who are its victims, would be regarded by most men as a person of very superfine morality.

America, for example, levies duties on the silks of France, which throw the inhabitants of populous French cities out of employment. In all the discussions which have arisen upon the question, nobody we believe has thought this was of the subject worth the public attention. The great manner of doing to others as we would have them do to us, has not been thought worthy of quoting in a question affecting the interests of another nation. Every government, it is said, should take care of its own subjects. As the world is now governed, this is done. When the people grow fierce with hunger, the government shoot them down. When the looms, which you hear clashing in every street of populous Lyons, are stilled by the check which American laws have given to the exportation of silks, the starving weaver, to escape the cries of his children for whom he has no food, walks out into the streets, discomfited with the order of society, and meets with others as discontented as himself. If they talk of their sufferings too loudly, and with demonstrations of impatience, they are arrested by men in Louis Philippe's uniform; if this does not restore tranquility, there are the batteries of the enclosing fortifications ready to be opened upon them. What is the recipe of the British government for appeasing the tumults caused by the starvation of the British operatives? A detachment of the military, powder and ball. It is thus that governments take care of their subjects when the legislation of other countries leaves them without bread.

There is a numerous and respectable religious sect who bear their testimony against war, and peace societies have been formed all over our country, of which men of all denominations are members, including some of the greatest intellects of the age. Do not this sect and these societies, we have sometimes asked ourselves, mistake their true object, and have they not put the effect for the cause? Might not their exertions be better directed to do away that miserable contest of selfish legislation out of which spring so many misunderstandings as many mutual discontents, so many rooted prejudices, of which actual war is but the natural consequence?

If we bring famine upon the laborious classes in other countries, it matters little whether it is done by a statute or an invasion; it matters little whether we point against them the weapons of their own government or of our armies. The whole protective system, as it is called, is as much a system of mutual annoyance as a state of war; the evils it inflicts are certain, the benefits it brings are imaginary. It is a struggle between nations to do each other harm, to cut off the branches of life in luxury by which each other's population is fed, to exclude each other from the markets in which their industry meets its fair reward. It is a sleepless warfare upon each other's prosperity, as malignant almost as harmful as if it were carried on with the sensible array of war, with ordinance and batteries, with fleets and embattled hosts. Its effect is to destroy property, to annihilate capital, to frustrate enterprise, to depopulate cities, to bring sudden destitution upon whole provinces. The world will never enjoy durable peace until it ceases to be the general policy of nations.

On the Different Breeds of Sheep.

[CONCLUDED FROM OUR LAST.]

In describing the Merino sheep, it may be advisable, previous to tracing their spread over other parts of the world, to give some account of them as they are found in Spain, their native country.

I do not deem it at all essential, in doing this, to go far back into the history of the Saxons, older than to mention the history of the Moors, whose power has never been the theme of most writers; and the costliness of their costume has, at all times, been dilated upon in all the glowing terms of fable and romance.

The expulsions of the Saracens from Spain, destroyed, however, the woollen manufactures of that country; and we are told that Ferdinand the 5th banished nearly one hundred thousand industrious people, because they wore Moors.

Philip 3d, his successor, drove from Valencia one hundred and forty thousand of the Mohammedan inhabitants; and in the three following years six hundred thousand were expelled from Murcia, Seville, and Granada.

Notwithstanding the political changes of the country, the total loss of its manufactures, and the consequent neglect with which they were treated, the Merino sheep seem to have been perpetuated in all their purity.

The sheep of Spain are divided into two great classes—the Stationary and the Migratory.

The Stationary sheep are those which remain the whole year on one farm or district; while the Migratory, are those which are driven from one part of the country to another, periodically, in search of pasture.

The Stationary sheep are said to consist of two distinct breeds, and a third or intermediate one. The first is the *Chacal*, and is altogether different from the Merino, being the breed of the peasant and small proprietor. The other principal breed of Stationary sheep is, the *true Merino*—and the third, which are found in every part of Spain, are a various mixed breed, the produce of the two former—the value depending upon the amount of the Merino blood in them.

The Migratory, or those which are driven to the mountains in the summer, and to the plains in the south of Spain in the winter, are the description of sheep by so many countries have been enriched, and the character of which it is here attempted to explain. These, like the Stationary sheep, are divided into two classes, and are known as the *Leonesa*, and the *Soriana*, which names they take from the different parts of the mountains to which they are driven. It is not the intention, here, to trace the operations of the sheep-breeders of Spain, or to give any account of the semi-annual marches of these flocks, from one extremity of the Kingdom to the other;—though it is a subject well worthy the attention of the careful and judicious farmer, in as far as climate appears to be of the greatest importance. These two divisions of the Migratory sheep of Spain, viz: the *Leonesa* and *Soriana*, are again divided into particular breeds, as the *Escorial*, *Gaudeloupe*, *Puñalar*, *Infantados*, and *Negretti*—the last being the largest and strongest of all the Spanish travelling sheep.

The general impression made by the Merino sheep, upon persons unacquainted with them, would be unfavorable;—the legs being long, though small in the knee; the breast and back narrow; the sides somewhat flat; the shoulders and humps heavy; and a considerable portion of their weight, carried on their carcase parts. Both male and female have a large tuft of hair growing on the forehead and cheeks, which should be always cut away previous to shearing; they have an extraordinary looseness of skin under the neck, which gives them a *throatiness*, which, in England, is looked upon as a bad property, while in Spain it is the very reverse, and esteemed as denoting a tendency both to wool and to a heavy fleece. Such throatiness is said to be characteristic of no aptitude to fatten; and this appears to be a matter not considered of sufficient importance to call attention, the fleece being the only object.

In following the importations of the Merino into England, which took place under the immediate patronage of George the 3d, it is hardly necessary to give any account of the first lot of sheep which arrived in that country. They were picked up without that attention to selection, which forms so important an essential, and consequently fell very short of the expectation which had been raised upon them. An application was then made, directly to the Spanish government, for permission to purchase a small flock; and consent having been obtained, a limited number were collected, of the *Negretti* breed, and shipped to England in 1781. The product of the second and third

shearings was compared with the best sample of imported Spanish wool, and it yielded not to them in any of the properties of fineness or felting. The same comparison was kept up for many years, with equally satisfactory results; and many of the most spirited breeders experimented upon the effects of crossing up on the various native breeds of England, reporting the result. There appears to have been a prejudiced form of resistance then; and it was thirty years after the arrival of the *Negretti* flock, before it was thought prudent to expose any of them to public sale. It was not my intention to detail the Merino mania which followed; it is enough to mention that a society was established, with Sir Joseph Banks as its President, with fifty-four Vice Presidents, and local committees in every county in England, Scotland, Wales, and Ireland; expensive premiums were awarded, or every inducement offered to persuade the farmer generally to give the preference to this breed of sheep. Their decay in the public estimation, however, became as rapid and as extensive, as their value on the other hand had been overrated, and that for the most simple of all reasons. The British people are susceptible of other peculiarities, especially *eters of nation*, and to satisfy their tastes, every thing has been overlooked to produce a sheep for the butcher; and in this respect the Merino is entirely deficient. The carcase did not afford a remuneratory price, and they were consequently abandoned. Again, the British shew wools, that is, the *Southdowns*, &c. though not in use for the finest of broadcloths, are equally valuable in their respective departments of manufacture; while the carcase fetches the highest price with the grocer &c. These two circumstances combined, produce the farmer a more certain, and, on the whole, a better remuneration than can possibly be gained by breeding the Merino. They are, notwithstanding, a fine valuable breed of sheep, and yield a wool which, for fineness and felting properties, is unequalled; and, though literally given up in England, the *Anglo-Merino* may occasionally be found in high perfection. *Lo Western*, their special patron, has paid every attention to them and has considerably improved his flock by a cross of the Saxony-Merino upon the original importation to England. This has been likewise the case with other breeders, not only in England, but Ireland also, where they are said to have improved rather than deteriorated.

The importation of the Merino into Saxony, took place in 1765; the Elector purchasing one hundred rams and two hundred ewes, of the most improved Spanish flocks, and placing them on one of his own farms, near Dresden. The prejudice against invasion was strong, and the greatest difficulty prevailed in inducing the sheep masters to make any allusion in the systems which they had imbibed. The Elector, however, having assured himself that it could be naturalized without any deterioration in the quality of wool, took measures to carry out his view which seem unworthily so good a cause—he compelled those who occupied land under him, to buy a certain number of Merino sheep. This compulsory system was happily of short duration; the farmers generally were brought to see their own interest; the naturalization of the Merino in Saxony was perfected; it bred rapidly increased; and after a few years a fleece of the Saxony-Merino became superior in fineness and manufacturing properties, to that of a Spanish.

One of the greatest causes, however, to the production of such results, was *education*. The Elector aware that nothing could be done where ignorance prevailed, took the true and legitimate method of moving this obstacle; and under the auspices of a government of Saxony, AN AGRICULTURAL SCHOOL and other minor schools, for shepherds, were established; and publications, which plainly and intelligibly explained the real value and proper management not only of the Merino sheep, but of every other description of domestic live-stock, were distributed. To full effect implementation of his purpose, was the Elector; and he had the gratification of knowing, that by this enlightened policy, he had assisted materially in forming the foundation of the wealth and the happiness of his country.

It is impossible to pass over this example, without calling the attention of the farmers of America, the most important of all subjects now agitating the minds of the reflective part of the agricultural population—I allude to the *National Agricultural Association*. Such results as those which have taken place in Saxony, must necessarily follow a similar eye in this country; and it behooves every man, who has the least particle of patriotism in his blood, to stand forward at this time, and give the necessary assistance to this great National undertaking. No man who

consider himself of not sufficient importance, to make himself especially a party to the work. There is no man or child in the whole community, whose interest not completely wound up in its being fully carried out—and no one can stand aloof, without being asured, that he is recreant to the interests of his family, and to the prosperity and independence of his country. Every man may do a little—merely talking up the subject, will go a long way towards its sure establishment; the attention once led to it, its advantages must necessarily present themselves to view; and every man, be his present opinions what they may, by *reiteration*, must necessarily prove himself a friend of the cause. But enough—the matter is in better and more efficient hands.

I will now make some few observations on the *Memo* sheep in New South Wales. The climate of the country seems better adapted to sheep, than any other I discovered on the globe; and from all accounts appears to operate so decidedly, as to be an exception to the fundamental principle, of the *paramount influence of blood*—no sheep have been imported into that country, without the most rapid improvement immediately taking place, not only in the roundness and compactness of body, but in the fineness and length of the fleece.

The history of the introduction of the Merino into this country, I will leave for the subject of my next essay.

Lonely but Good Advice to Readers and Editor.

Whoever reads the annexed article, will not be surprised that we publish it. As far as our readers are concerned, we shall not intrude upon their province and say that they ought to follow this counsel. It is quite enough to receive advice at first hands, without, what grammarians call a *republication*, and being advised to take advice. But for ourselves, we at once agree to our friend's proposition, that we should have a regular correspondent in every town, not only in the state, but in every town where our paper has the honor of being admitted, to whom we should send two copies; and who would, in return, agree to assist the circulation, and especially to furnish valuable information for its columns. But with a limited acquaintance, how shall we effect this, unless the friends of the cause volunteer? We hope they will do this in the spirit of our respected correspondent, and we promise to meet them full halfway.

It is said that on a certain occasion, a minister having named his text, "Who will go up with us to Ramoth Gilead to battle?" and repeating it once or twice with considerable emphasis, a sailor in the assembly, much vexed with the silence and apathy of the congregation, rose at once, and said with considerable feeling, that "if there was nobody else to go, he would go for one." Now having announced our text to our brother farmers, we hope we may find a good many all over the country, who will follow this brave fellow's example. It is in vain for the lead horse or the filly horse to think of drawing the load alone. Let us pull together.

Mr. Editor—I want every farmer in Western New York to become a subscriber for the *New Genesee Farmer*, and not only a subscriber, but also a constant reader. Brother farmers, who are now readers, what do you say, shall we bring this about? Yes we;—you reader, and I and all the rest of us;—I am quite sure we can do it. Come, let us all put our shoulders to the wheel and try! But how? I will tell you. Every one of you, when you get through reading this communication, take this number of the *Farmer* in your pocket, go through your neighborhood and call upon every man to subscribe. Talk to him "like a book." Tell him how much you have been interested by the perusal of it; and how great the advantages that will result to him if he will only take it—even for one year—one cent a week is all it costs,

and the money will never be missed from his purse. Come brother, subscriber, let us "put in" once, and see what the result will be. Let us count up, there are 20,000 of us now; well, I will agree to procure five, each of you will do the same, this will make 100,000; here we will rest our labours for the present, and if our new Editor "does the fair thing" this year, and "the old folks" conclude to let him stay, why next year we will double the list, that's all. I feel quite confident the *New Genesee Farmer* may be made to take a high rank among the agricultural papers of the United States, and that it will be conducted in a manner deserving of as extended a circulation as we can give to it.

But, Mr. Editor, I have said sufficient to your subscribers, now I have a plan to suggest for your consideration, which I think will not only add interest and usefulness to your paper, but also greatly increase the number of your subscribers. I propose that you appoint a regular correspondent in each town in Western New York, send him two copies of the *Farmer*, one for himself the other to be loaned or circulated by him to such farmers in his town as may not be subscribers, to be returned to the correspondent when read, and by him again loaned to some other person, and so proceed until every farmer in town shall at least have read one number annually. I cannot but think, that this plan would awaken a more general interest in the farming community towards agricultural papers, and have a tendency to do away a deep-rooted prejudice which still exists among some of our most respectable farmers, against what is called "book farming." It would bring your paper to the notice of hundreds, yea thousands, who now know not that such a paper is published, and add many names to your list, which, except by this means, would never have been found there.

It will be the duty of the correspondent also, to report for your columns, accounts of extraordinary crops, animals, &c., and all matters he may think worth recording, and after the harvesting of each variety of produce, a brief report of the amount of the crop upon an average through the town.

I have several other things to say to you Mr. Editor, but lest my communication should take up too much of your space, or be passed over by the reader on account of its length, I shall refrain.

J. HORSFIELD.

Castile, Wyoming Co., N. Y.

Making Butter.

From a lady correspondent we have the following method of making butter, by first scalding the milk. The mode is sometimes called the Russian, sometimes the Scotch, and sometimes the English. It may just as well be called the American mode, for it has been long practised among us. Twenty-six years ago we saw it in full practice in a dairy of a hundred cows, on the farm of Robert Smith, near Baltimore. It has much to recommend it, and especially from the sweetness of the cream, the milk not standing more than twenty-four hours, or it may be twelve hours; from the ease and quickness with which the butter was usually brought, the churning seldom requiring but few minutes; and lastly, from the improved quality of the skimmed milk, which by being heated, was thickened and made richer; and in the case above referred to, brought three cents a quart at the entrance of the city, where it was sold to a retail dealer.

Mr. Editor—As there are many different ways of making butter, and each has its advocates and its opposers, I have thought the following would be of some service. It is copied from an old English work. "The milk, instead of being put into earthen pans, as with us, is poured into copper or

brass pans, well tinned, and after standing a certain time, these pans are placed on stoves heated by charcoal. The heat causes the cream to rise in a few minutes to the surface of the milk in a thick consistency, called clotted cream. When it has remained a certain time on the stove, and has sufficiently warmed, it is returned into the dairy, and as soon as cold, the clotted cream is skimmed off, put into a large earthen bowl, and by the slight movement with the hands or a wooden spatula, is almost instantaneously converted into butter. Very little buttermilk of course, is pressed from the cream thus prepared, and what is, is remarkably rich." Almost every one has noticed that when milk is boiled, there is a scum rises upon it, and also that it has a very delicious taste. This method is certainly well worthy of a trial. HANNAH.

Farmer's Winter Memoranda.

The winter is now somewhat far spent, and farmers who wish to be well prepared for the coming of spring and its hundred labors, must improve the time in making the following preparations; viz:—

REPAIR ALL YOUR TOOLS.

Rakes, for horse and hand, should have broken teeth supplied;

Hoes, should be good, sharp, and have good handles;

Forks, do. do.

Ploughs—the wood should be sound, and the shares good;

Harrows, cultivators, rollers, should all be put in good condition;

Carts and wagons prepared for use;

Harness well repaired and oiled, and

Horses kept in good order to wear it when the time comes, by good, regular, and careful feeding.

SEEDS of all kinds should now be obtained, clover, barley, corn, oats, &c., and of root crops, as beets, carrots, turnips; and don't forget the garden seeds.

GRAFTS of fine fruit may be procured; every man should endeavor to add something each year to his stock, (as *fruit stocks* and *farm stock*, are the best kind of *stocks* a farmer can speculate in,) if he only spends half a day for the purpose in each year.

Grafting plants may be now made—use 8 parts resin, 4 of beeswax, and 3 of tallow, melted and spread on old cotton, or paper, to be warmed over a kettle of coals before applied.

Trim apple trees—old bearing trees—that have thick branches; and prune hardy grape vines; so that they may not grow so dense, and have finer fruit. And don't forget to tread round young fruit trees, when deep snow falls, to exclude the mice.

Repair fences, where practicable, especially where the boards have been loosened from the posts; and observe the same towards gates.

Fuel—get plenty and cut up for summer use;

Manure—manufacture as much as you can, now, this winter; and procure

Plaster, for early spring sowing. J. J. T.

Important Suggestion, at this time of the year.

According to Liebig, (and the evidence of our senses, too,) a large portion of the valuable part of manure, escapes from stables and other places of collection, in the form of gaseous ammonia. Now by strewing the floors of stables with gypsum, this gaseous manure immediately combines with the sulphuric acid of the gypsum, forming a solid compound, destitute of smell, and of great value as manure. The offensive odor is destroyed and the manure is retained. Those who have tight stables may successfully try this with great ease. J. J. T.

Importance of the quality of the Salt used in making Butter.

At a late Agricultural meeting in Augusta Me., Dr. Bates stated that the Quakers in Fairfield were in the habit of buying the best description of coarse salt and cleansing it, and having it ground, and this salt they used in the manufacture of butter. The consequence was the butter made by the Quakers of Fairfield, had a better reputation and bore a higher price than the butter made in other towns. He held them up as worthy of imitation. He stated that the loss of the butter manufactured in this State was greater in amount every year than the sum raised for the State tax—more than four hundred thousand dollars. He believed that, if this fact was generally understood, if the people could be made aware of the loss incurred by bad manufacture, we should at once see an improvement in this article of which is so much produced and which enter into our daily consumption.—*Maine Farmer.*

Hung or Brined Beef.

The recipe of a successful turner, is as follows:
Eight oz. of salt, 1 made into
Two oz. of salt-water, 1 brine.

This quantity, to be applied to ten lbs. of beef. It should be in the brine four weeks; and then be hung up in the kitchen to dry. In summer to preserve it from insects, it should be tied up in a linen cloth.

YEAST.—Boil one pound of good flour, a quarter of a pound of brown sugar, and a little salt, in two gallons of water for an hour; let it afterwards stand until it becomes milk warm, bottle it and cork it close. It will be fit for use in twenty-four hours. One pint of this will make eighteen pounds of bread.—[*Lady's Annual Reg.*]

The officer caplets are shaken, the longer they wear; the dirt that collects under them, grinds the threads.

See that the beef and pork are always under brine; and that the brine is sweet and clean.

Agents for the New Genesee Farmer.

In addition to the numerous Postmasters and other friends of Agriculture who have kindly aided the Circulation of this paper, the following persons will receive Subscriptions in their different towns and cities
Baton, Mass. Messrs Little and Brown; Ruggles

Norras and Mason; Hovey & Co.

A Wherryman Wanted, in Ohio.

I, the proprietor of a well established and favorably situated Nursery Garden at Columbus, Ohio, wishes to engage a man of some experience in the business, to take the management of the establishment, either as a partner, or as salary. Address, if by letter post-paid.

J. A. LAZELL.

Columbus, Ohio, Feb. 1, 1842.

CLOVER AND TIMOTHY SEED.

OF the best quality, free from bad seeds. For sale at the Seed Store.

M. B. BATEMAN.

GREAT SALE OF BLOODED STOCK.

I propose to sell by Public Auction, on Tuesday 29th of March, at my farm in Greece, adjoining the Erie Canal, six miles west of Rochester, all my blooded and grade stock, including my choice Durham Cattle, Horses, Leicester Grey and Hags, the remainder of which, with pedigrees of the same, will be given at a future day.

THOS WEDDLE.

Rochester, Jan. 25, 1842

Rochester Seed Store and Agricultural Repository.

THE proprietor of this establishment, would now inform his friends, that having relinquished the charge of the New Genesee Farmer, (to add laborers,) he will hereafter devote his whole attention to the business of the Store, confident that he will thereby give increased satisfaction to his customers. A full supply of nearly all kinds of SEEDS are now on hand for the ensuing season; a part of them raised in this vicinity the past season, by C. F. CROSBY, and other careful seed-growers, and the rest obtained from the most respectable foreign sources. Knowing that success in agriculture must depend on the quality of the seed, we wish to have it served out what they should be of the right kinds and the best quality.

OF AGRICULTURAL IMPLEMENTS, GARDEN TOOLS, BUCKS, &c., there is good stock on hand, but many more will be obtained in the spring, when it is intended to enlarge the establishment so as to allow more room for this class of articles.

MERCHANTS will be supplied with seeds for retailing, at very low prices. The usual number of Agents will receive assortments on commission as heretofore, during the winter.

Our CATALOGUES will be furnished soon.
Rochester, Feb. 1st, 1842. M. B. BATEMAN.

FRUIT TREES.

THE subscriber is now and will continue to furnish in large or small quantities, the finest varieties of Fruit Trees, Flowering Shrubs, Herbaceous plants, Bulbous Flower roots, Double Dahlias, Green house plants, &c. &c. Also, C. F. CROSBY, of Rochester, N. Y., has put up in boxes or packages to order; all of which are warranted genuine as represented, and of superior quality.

Orders for the Spring will be promptly attended to on very liberal terms, when accompanied with cash or satisfactory references.

Selections will be made by the proprietor, when requested.
Rochester, Feb. 1st, 1842. C. F. CROSBY.

THE NEW GENESEE FARMER, AND GARDENER'S JOURNAL.

VOLUME THREE—FOR 1842.

THE Cheapest Agricultural paper in the country.—6 Large Pages Monthly, (with engravings.) only 50 cents per year.

HENRY COLMAN, EDITOR.

(Late Agricultural Commissioner of the State of Massachusetts, and Editor of the New York Farmer.)

Grateful for the extensive patronage which the New Genesee Farmer has received during the past year, the proprietor now has the satisfaction of announcing that he has made such arrangements for continuing year as cannot fail to be highly gratifying to the readers of the paper, and secure for it a still more extensive circulation.

Desiring to make it the most useful and widely circulating agricultural paper in the Union, the proprietor has engaged the services of the celebrated and eminent agricultural writer and orator, HENRY COLMAN, well known as the late Agricultural Commissioner of the State of Massachusetts, and formerly editor of the New England Farmer. Depending on the co-operation and support of the friends of agriculture in the Empire State and the Great West, Mr. Colman has consented to leave his native land, and has labored with so much honor and success, and located at Rochester, where, through the medium of the Genesee Farmer, he expects to find a more extensive field of usefulness.

Post Masters and their Associates are authorized and respectfully solicited to act as Agents and remit subscriptions for the Farmer. The low price at which it is published will not allow of much pecuniary compensation to Agents, but it is believed they will be induced to bestow the patronage which result from the circulation of such periodicals in their neighborhoods.

Persons ordering papers are requested to strictly observe the Agents, and be careful to write & please the names of subscribers, their Post Office, County, and State; and in all cases to send the money with the order, so that the perplexity of keeping accounts may be avoided.

M. B. BATEMAN, Proprietor.

TERMS.—If current money is sent (such as New York or New England bills) commission will be allowed as follows:

Seven copies, for \$5.00 Payment advanced to be Twelve do. for 5.00 made in advance to be Twenty-five do. for 10.00

No commission will be allowed if current money is sent.

Address, BATEMAN & COLMAN.

December 1, 1841. Rochester, N. Y.

NEW CUSTOM MILL.—The subscriber having taken the White Mill on Water Street, East side of the river for the purpose of running it as a Custom Mill would give to all who will be now prepared to do work as short a time and as well as he ever has in New York State. He has the facilities and a close application to business, he is in hopes of merit and obtaining a share of public patronage.

Wheat, Rye, and Corn, all kinds of Wheat, all Barley, Beans, Oats, Peas, Grass Seed, Flax Seed, Buckwheat, Rice Wax and dried Fruit: for which the highest market price will be paid.

N. B. Flour will be at all times on hand, subject to the most reasonable terms for merchants or others who wish grain ground.

W. C. FOSTER.

Rochester, January 1, 1842. 3m

A FINE FARM FOR SALE.—Of fifty acres of choice land, situated about 1 and a half miles from the centre of the flourishing city of Rochester, N. Y. on the south-east end of the lot, from Monroe street, and within a mile from the city line. A new house, barn, and fences—a fine orchard, good wood and water, &c.

For further particulars, enquire on the premises, or address C. W. C. to Rochester Post Office, N. Y. Postpaid.

Rochester, Dec. 25th, 1841.

MILLIS'S ROOT CUTTER.

Having for several years past had numerous inquiries from those who are desirous of procuring a machine for cutting vegetables for feeding stock, and the satisfaction of the public, the subscriber has been enabled to procure some that just the thing wanted. The following recommendation C. N. BENTON has published in the Albany Cultivator, clearly sets forth the advantages of the Machine.

"As much attention has been paid of late to the culture of roots for feeding stock, &c. At first some difficulty occurred in getting the roots cut in the best manner, the subject labor to a machine. Where a large stock were fed, much time and labor was spent in slicing or cutting the roots suitable for feeding with safety. At first the spade, sickle, a chisel were brought into requisition, but not satisfactory. Other machines have since been used, such as the Grater, horizontal Knives, operated by a team. But Millis's Vegetable Cutter eclipses the whole. It consists of a box, seven long, 2 feet wide, 18 1/2 high, with a hopper and a receiver or spout below. Near the centre of the box is a frame bearing a circular plate of cast iron on a horizontal axis to which a crank is attached, the wheel carries three knives set parallel to the face of the plate and radiating from the centre, the vegetable presses against the knife and their own weight keeps them within the stroke of the knives.

They will cut more potatoes into thin slices in one hour than a man can cut in two days with a knife. I find that Vegetables cut in this machine, will not rot in a mud t barrel, making a great saving of space. I have cut 200 lb. of chine cuts potatoes, turnips, beets, cabbage stumps, pumpkins and squashes, when broken, with ease. The above given to answer the many enquiries made, which it is believed will be highly satisfactory for the sake of the vegetable garden for feeding stock. C. N. BENTON.

For sale at the Rochester Seed Store—Price \$10.
Jan. 1st, 1842. M. B. BATEMAN.

For Contents see last page.

PUBLISHERS' NOTICES.

[*Can't Take It!*] verily these are troublous times. The Currency of the country is in a state of confounded confusion, and we are compelled to inform our distant friends that for the present, we cannot consent to receive the *promises to pay* of the Banks in Pennsylvania, Ohio, Indiana, and Illinois. The Brokers refuse to purchase them, and we have no means of using them. These circumstances will of course affect our circulation in those States for the present, but we hope this panic will not last many months. As soon as the Banks resume payment their bills will be received.

To our friends in this State and New England, we would say our dependence is upon you. Our Western patronage is now mostly cut off and we must rely upon you to make up the deficiency, from those States where the Currency is not so deranged.—Our increased expenses require, and we trust *deserve*, an increase of revenue.

Acknowledgements.—We cannot write letters of thanks to the numerous kind friends who have thus far nobly added us, but we hope they will not on that account do us the injustice to suppose that we are ungrateful or that their favors are forgotten. Without their aid this paper could not exist, and therefore the country is indebted to them for whatever benefits result from its circulation.

A Meeting of the Monroe Co. Agricultural Society.

Will be held at the Arcade, Rochester on Thursday the 17th inst, at 10 o'clock for the purpose of making out a list of premiums and appointing Awarding Committees for the next Annual Fair. This is a very important meeting and it is hoped that all who feel an interest in the Society, and especially all the officers, managers and town-committee men will be present. (See the list in another column.)

A Farmer's Dinner will be provided at the Arcade House—price 25 cents.

CORRESPONDENCE.

We cannot but feel highly gratified with the many kind letters which we have received, of which the following is an example, from one of the most intelligent and public spirited farmers in Western New York.—He will pardon us for omitting a portion more strictly personal. These letters proffer us a cordial welcome to Western New York, and invitations to visit the homes of the farmers who write them. For the welcome we are heartily thankful, and the invitations we accept with an equal pleasure. We desire no higher honor in this world than to be accounted the Farmers' Friend; and we can ask to render no higher service to our fellow men than to contribute what we can in inducing the farmers to form a just appreciation of the usefulness and dignity of their profession, to enjoy with a higher zeal, its pure and honest satisfactions; and to improve and increase to their utmost capacity, its great, but as yet, not half explored advantages.

Letter I. Agricultural Improvement. MR. COLMAN:—

Be assured, Dear Sir, that you are not alone in the "pleasure" which you experience, "that the Editor is at home in Rochester," yet *not so* "at home in Rochester" it is hoped, that other parts of Western New York will not receive his visits; even further West than Monroe County. For the "hospitalities" of "Niagara" will doubtless be as warm and as spontaneous, as those of "Wheland" even. I am glad he "does not intend to stand much upon ceremony," for whether the "banes" be published or not, is of very little consequence, as that is not, in this state, a pre-requisite to the "nuptials."

It is to be hoped, however, that when the Editor goes abroad among our agricultural community; he will bear in mind that he is not in the "Old Bay State" where the lands have been cultivated more than two hundred years, and that too, with much skill and industry; but that he is in the "Genesee country," where for three fourths of that period, this whole region was inhabited, only by the red men of the forest. We are emphatically, in our agricultural youth, for, as a community, we have for the most part been able barely to pay the exorbitant price for our lands,—clear them of the unbroken and heavy forest,—and support our families. As to the matter of ornamental improvements which so greatly abound in your native State, very little can be seen in this region; although some few are beginning to feel a little comfortable in their circumstances. But the great majority of us are, or pretend we are, too poor, and too much in debt, even, to pay fifty cents a year for an agricultural paper: and of course, you will not expect to find us very far advanced in scientific husbandry.

You will doubtless find, Mr. Editor, in the greater part of Western New York, that although we possess one of the most desirable agricultural districts in the world; yet, we cultivate our lands, not as science and wisdom would dictate.

One of the greatest errors of our practice, is the indifferent and slovenly manner in which we manage our crops.

A very general stupidity in regard to the idea of improvements in husbandry, prevails among us. If we raise from 15 to 20 bushels of wheat, 30 to 40 of corn, 100 or 180 of potatoes per acre, we are tolerably well satisfied, and trudge along in the old track of our fathers. And when we, perchance, hear that "somewhere down east," crops of grain are raised, double or triple to ours, we discredit the story, instead of enquiring how it was done.

But enough for the present, lest the Editor should feel discouraged, without even a visit to his new friend NIAGARA.

Thorn Hill, February, 1842.

We subjoin extracts from the kind letter of another correspondent, showing the most substantial proofs of his good will. We can only thank him, and promise to do our best to justify his good opinions, and make

our paper worthy of his exertions. The exertions of our friends Cook and Horsfield remind us of a kind-hearted Frenchman. A poor fellow had been burnt out and lost a large amount of property. A crowd of friends the ensuing morning were round him commiserating his misfortune, and saying very kindly that they pitied him. The Frenchman heard them with some little impatience. Oh! said he, my good friend, you all say you pity this poor man ver much, but you no say how much. Now I pity him one piece linen; and gave the poor fellow a piece of linen.— This was real kindness; and if it did not savor too much of the shop, we should call this showing one's faith by one's works, a very commendable kind of religion in the apostle's time. We say nothing of modern improvements in this matter.

LETTER II.

A Friend in need, a Friend indeed.

MR. EDITOR:—In looking over the contents of the last Farmer, I was much pleased with a communication from your correspondent J. Horsfield, in which he calls upon all the readers of the Farmer to "take this No. and go through their neighborhood and call upon every man to subscribe." Well, agreeably to his plan, I took the paper and started, and in a short time I obtained ten subscribers, and in no case was I under the necessity of urging them or "talking to them like a Book," but on examining the paper and learning the terms, they very willingly paid over to me fifty cents, with the request to have it forwarded immediately.

Your correspondent proposes that every one of the present subscribers should obtain five new ones. Now I most earnestly hope this request will be complied with; but I would not limit the number to five. I would say to every one, *get all you can*. If you cannot get but one, get that; and if you can get five, ten or twenty, so much the better. I have already obtained ten, and I do not intend to stop here, but hope I shall soon be able to send you another list of names. If I could make my voice be heard by every Farmer in Western New York, I would say to them, take the Genesee Farmer, and not only take it but read it.—The benefits to be derived from it are very great, and its cost very small. *It is our own paper*, and we ought to use all our influence to sustain it.

I hope the subscription list for this volume will show that the farmers of Western New York give our new Editor a hearty welcome.

I am glad to learn that he is at home in Rochester, where I intend soon to give him a call and talk over matters and things; should it be consistent with his other engagements, I should be happy to have a call from him on my farm in Byron, Genesee County.

Very respectfully, Yours, IRA COOK.

Agricultural Chemistry.

The premiums of the New York State Agricultural Society for 1842, will appear in our next. They offer a premium of 100 dollars for the best Essay on Agricultural Chemistry, of which we hope our Eastern friends, S. L. D., and J. E. T., and C. F. J., and J. W. W., will take due notice, and govern themselves accordingly.

Inquiry.—Indian Corn for Fodder.

MR. EDITOR—

I wish to sow two or three acres of corn for the fodder, and not being acquainted with the crop, I should like to be informed as to the quantity of seed to be sown per acre, the time of sowing, the manner of tilling or putting in the crop, at what time the crop should be cut up, and all other little particulars concerning it, that I may be successful in the experiment.

If you will give the necessary information through your paper, you will afford many subscribers valuable information. If such a crop will produce from five to seven tons per acre—after being cured—as some persons pretend that it will, it would be well for farmers to understand it.

Ledyard.

Cayuga Co., N. Y.

Remarks on the above.—The cultivation of Indian Corn for fodder may be well recommended to the farmers, especially where pasturage is deficient, or in a season where the crop of hay is likely to be small. Among the farmers who supply the cities with milk, it is a favorite crop, and is given to their cows at night and morning to assist a short pasture. In such cases it is sowed at successive seasons, every week or fortnight, so that the crop may be coming on as needed. It is sometimes cut when it is knee-high, and then in general it will start a second time, so that another cutting may be obtained. This should not, however, be confidently relied upon. Where it is wanted for green feed, it is of course advisable not to cut it until the plant is in perfection; we do not mean until the seed is ripened, but until the leaves and stems are as abundant and large as they are likely to be; that is when the flower is protruded, and the ear formed, and yet no part of the plant has become too hard to be completely eaten up by the cattle. Every farmer, therefore, may make his calculation as to the time of planting. The earlier he plants, the sooner he will have the fodder and the more of it to give to his stock; and by planting at successive times according to his convenience, he may keep up a supply of succulent food to the very end of the season. None need be lost; and every leaf and stem of it should be saved, even after the frost has killed it.

We have seen the plant cultivated to great advantage for soiling cows; in many instances; in one where twenty cows were kept; in another where a hundred cows were soiled. In the latter case several acres were sown with corn for this purpose; and it was cut and brought into the barn as wanted. There was no feed of which the stock were more fond; none which produced more milk; and none obtained at a less expense. It was all cut short by a machine, and while gathered green every particle of it was consumed. When in the autumn it became dry, it was steamed for the stock. Among the milk farmers, near the cities, its cultivation is constantly increasing.

We have known it likewise much used for store hogs. Where pasturage is deficient, or where they are kept in sties, no green food is more relished by them or more conducive to their thrift. In this case, however, it is of course given to them in a green and succulent state.

We have not known it cultivated extensively for winter fodder, but there is no reason why it should not be. In this case it would be desirable to sow it early, if we would have the largest crop, and let it come to what maturity it will. The value of well-cured corn fodder for stock is settled. The cattle have determined the question long ago by

the relish with which they eat it; and the good condition in which it keeps them. The amount of well-dried corn fodder, including butts as well as tops, where the crop is fifty bushels, is generally estimated at two tons; this of the small yellow flint variety of corn; the southern gourd seed variety and the Western corn, produce a much larger amount. Farmers in general are disposed to estimate the fodder upon such an acre of corn, well saved, as equal for any neat stock, to one ton of English hay. Some place it at one and a half ton; none lower than three fourths of a ton.

The only instance, which has come within our knowledge, of ascertaining with any exactness the actual amount of fodder or stover upon an acre, was in Pennsylvania, where we infer the gourd seed variety was cultivated, and where the crop amounted to 66 bushels. In this case

	Tons.	cwt.	lbs.
The blades, husks and tops, when cured, amounted to	1	6	13
Stalks and butts	1	7	00
	2	13	13

How much could be obtained by sowing it exclusively for fodder, we have no means of determining with any accuracy.

Nor have we any certain prescription to give as to the amount of seed to be used for an acre; certainly not less than half a bushel, nor more than two bushels. Corn is a plant which, in rich soil, tillers abundantly or throws out many suckers, unless where it is very thickly sown, in which case it conforms to every other plant in its habits of growth, and runs up in a slender form like bushes in a thick swamp. Many persons advise to sow it broad cast, in which case it admits of no after cultivation; and the weeds, if the land is rich, will check its growth and fill the ground with their seeds. It is best to sow it in drills two feet apart, and quite thickly in the drills, scattering the seed over a space in the row, six inches or a foot in width. It may then be ploughed or passed through with a cultivator once at least; and in a measure keep clean from weeds. It is believed that as much fodder may in this way be obtained from an acre, as if sown broad cast.

The land cannot be made too rich for it; and it need not be gathered until it is ripe. There may be a good many imperfect and some ripened ears among it; but the cattle will not like it the less on that account. The Irishman was asked how he kept his horse so sleek and fat; and "faith!" says honest Pat, he has nothing but white straw, your honor, and that is not *half threshed*." It is a prevalent opinion that the top stalks of Indian corn when cut in a succulent state, and cured quite green, are better than when left to ripen. It is believed that this is an error; as the experience of observing farmers, we think, will show that their cattle do better, prefer them, give more milk and show better thrift, when fed upon the buttstalks, that is the leaves and husks upon the butts after the corn has been gathered, than upon the top stalks gathered and cured in a green state, as above described. The fodder need not then be harvested until it is, as it is termed, nearly dead ripe. Corn fodder when cut green, especially late in the season, is cured with great difficulty; but if left to stand until it is either killed by the frost or reaches maturity, it is as easily saved as hay. In putting away corn fodder, we have found it advantageous to insert occasionally, layers of wheat straw. The sweet flavor of the corn fodder is communicated in some measure to the straw; and the straw serves to keep the

corn fodder from being injured by heating. No fodder suffers more or sooner from wet or rain than corn fodder. Every possible pains should, therefore, be taken to avoid this; and it is a good way to hang as much of our corn fodder, as we have room for, on the beams and on poles extended over the barn floors, and in sheds where it will be out of the reach of the cattle.

As to the kind of corn to be sown, the Southern gourd-seed or the Western corn, will undoubtedly give the largest weight; but much of it will be in the butt, no part of which will the cattle eat. Our common Northern small flint corn will yield a large amount to the acre, as it will bear thick sowing; and the main stalk is not so large but that a good deal of it will be eaten, especially if cut up.

Improved Durham Short Horns as Milking Stock.

I subjoin a letter from Wm. K. Townsend, of New Haven, Conn., received since my Fourth Report of the Agriculture of Massachusetts was published. From this report an extract has been given, both in the number for February and in the January No., relating to DAIRY STOCK, in which the claims of this race are examined under the light of the fullest information which I had then obtained or could obtain. The reference made to the stock of Mr. Townsend in my Fourth Report, p 273. No. 7, was founded on the statement of the Committee on Farms of the New Haven Agricultural Society. Had his letter reached me in season, I should certainly have inserted it with pleasure.

There can be no doubt of the authority of this letter. It is worthy of full confidence, and speaks well for the milking properties of this valuable race. The quantities of milk reported are remarkable. The statement, however, is positive only as to three of the animals. "Lady," during the winter averaged 18 qts. per day, and in her prime and on full feed, gave 30 qts. per day. She was a selected cow.

"Favorite," her offspring, gave 22 qts. Having lost one teat, her greatest quantity since has been 24 quarts.

"Beauty," the daughter of Favorite, and grand daughter of Lady, gave 10 qts. on the morning of the day when she calved, and after that increased to 30 qts. per day, at which rate she continued for six or eight weeks. It is not said whether the measure was beer or wine quarts, but I presume the latter; 30 wine quarts would be equal to about 21 beer quarts. If the milk was measured in the pail, little reliance can be placed upon the exactness of the measurement. This case presents one among the frequent examples of the indefiniteness with which statements of this nature are made. It would have been gratifying to have been told how the cows were kept.

In respect likewise, to the right thorough bred Durhams, descendants from Lady, all, as Mr. T. says, superior milkers, and of whom he adds, we estimate their average yield for eight weeks after calving, at 24 qts. per day, on good feed; it will be seen that this is matter altogether of estimate, not of ascertainment. It must therefore be set down as such.

It is to be regretted that Mr. T. has made no trial of the better properties of the milk. The facts that "it brings the best price in the New Haven market," that "his family deemed it richer than the milk of native cows, when placed side by side," that "the milkman pronounced it the richest he had ever carried to market," and that "some of his customers consider it the best they can procure," are all valuable as opinions or presumptions in the case; and certainly without the slightest disparagement to, but with the highest respect for the judgment of the gentleman, who certifies this account, it will be seen that these are all matters of private opinion and judgment, and therefore by no

means conclusive as to the butter properties of the milk. This can only be certainly determined in the churn.

It was said to me at the meeting of the State Society at Albany, by two or three friends, that it was understood that *none* the New Genesee Farmer would come out as the opponent of the Durham Short Horns. I answer that no man has either right or reason to say this. I do not choose to be put in this position. I am not the opponent of the Short Horns; far from it. I am an admirer of this race of animals. But I am the friend of truth in the case, and I shall go for facts, and seek, as honestly as I can, to make up my judgment, and shall have no hesitation in avowing that judgment, when it is made up; and shall not be ashamed to alter that judgment when I see occasion to alter it, even at the risk of being tossed upon the horns of these cattle as high as the most stiff-necked among them or their advocates can throw me.

H. C.

East Haven, Conn., Dec. 10, 1841.

MR. H. COLMAN—

DEAR SIR—In compliance with your suggestion, communicated through H. Whitney, Esq., of New Haven, I will endeavor to give you a few statements respecting the quantity and quality of the milk from my thorough bred Durham cows.

"Lady," from whom my stock originated, was purchased in England by Henry De Groot, Esq., in May, 1829, of Asahel Ashcroft, Esq., of Bank Hale Farm, and was then four years old. She arrived in this country in July of that year, and on Dec. 23th, brought a fine heifer calf—named Favorite. Lady, during the winter succeeding, averaged 18 quarts, and when in her prime gave, while in full milk on good feed, 30 quarts per day.

At two years old, Favorite gave 22 quarts; but losing one teat by accident, her greatest quantity since has been 21 quarts.

Favorite's first calf, "Beauty," is a superior milker, giving milk freely up to the very day of calving. On the 4th of May last, she gave 10 quarts in the morning, and in the afternoon returned from the pasture with the calf she had dropped during the day, by her side, and gave an equal quantity. She immediately increased to 30 quarts a day, and so continued for 6 to 8 weeks, until the pastures failed from the drought.

I have eight thorough bred cows, descendants of Lady, and all superior milkers. We estimate their average quantity during the 8 weeks after calving, on good feed, at 24 quarts per day.

As all my milk, for several years, has been sold in New Haven, it has not been convenient for me to ascertain the precise quantity of butter which might be made from the milk of each cow. My milk is rich and sells readily at the highest price in the city, and is pronounced by good judges there, the best which can be obtained. Butter made by us from milk left occasionally, is of the first quality in color and in flavor, and the thickness of the cream, as compared with that upon the milk of native cows, placed side by side, has been such as to attract the notice of my family. The person who has purchased my milk for the year past, has had experience in the business, and he declares the milk from my Durham cows the richest he has ever taken to market.

Very respectfully, &c.

WM. K. TOWNSEND.

This certifies that I have used in my family, milk obtained from many different persons, but for the last year have procured my supply from Mr. Townsend's dairy, and that, I am fully satisfied, it is the best I can procure in the city.

CHARLES ROBINSON.

New Haven, Dec. 10, 1841.

Charles Robinson, who subscribes the above certificate, is one of the most active and enlight-

ened friends of Agricultural Improvement to be found in this good old Yankee State. We are happy to see his name affixed to any communication in our paper; and shall be much gratified to find it often appended to communications much longer. We assure him a hearty welcome whenever he will favor us, and a cordial co-operation, as far as our humble power can be exerted, in the cause which he and his disinterested coadjutors have so much at heart, the improvement of Connecticut Husbandry.

Durham and Devon Stock.

Mn. Editor—

SIR—In answer to an inquiry in the December number of the New Genesee Farmer, by A Subscriber, as to which I consider the best breed of cattle, the Durham or the Devon, I would say, that I have not had much experience with the Durham, excepting one bull. My oldest stock of that breed are only one year old last spring. They are quite large of their age and appear to be tolerable good feeders, but they have not that symmetry of shape that would be desirable, excepting these from Devon cows (crossed). I have raised crosses of the Devons for a number of years, and I think they are the best stock to cross with our native cows, being more uniform in shape and color, and in my judgment, are the best stock of cattle for the majority of farmers in the Genesee country, all things considered. They are very much sought after by eastern drovers.

GEORGE SHEFFER.

Wiscasset, Jan. 15, 1842.

Remarks—We give the above from a respectable farmer and agree with him, that he is a very incompetent judge of the Durham Stock if he has had none, excepting a bull, more than one year old. He as yet can hardly judge of their shape, as animals of a large size seldom attain perfection of size early.

The cross of the Devons with our best native stock, is most strongly to be recommended, especially in reference to raising oxen; how far it may improve the milking qualities of the cows remains to be determined.

That this cross constitutes the best stock for the Genesee Country, with our recent and imperfect knowledge of the localities, we shall not presume to give even an opinion.—En.

Berkshire Pigs.

Mr. E. Marks, in the last number of the Cultivator, gives the weight of four Berkshires,—1838 pounds; pretty good, to be sure. But we have some in this neighborhood quite their equals. Mr. Carter, who has taken four premiums on Berkshires of the Ontario Agricultural Society, fattened two out of a litter of eleven pigs, and slaughtered them the day they were twenty months old. Their aggregate weight was one thousand and forty-four pounds. Yours &c.

MYRON ADAMS.

East Bloomfield, Jan., 1842.

For the New Genesee Farmer

Peat.

MR. COLMAN—There has recently been discovered in this vicinity, an extensive bed of peat. It is situated about midway between the villages of East and West Bloomfield, half a mile North of the road. It is found in a whorleberry swamp, comprising some sixty or seventy acres. The discovery was accidental. A man passing on the bank of a ditch during the very dry weather of last autumn, observed the muck thrown out of the ditch to be hard, and crumbling under his feet like charcoal, was induced to try some of it in a blacksmith's fire, and found that it burned readily. The swamp was burned over last fall, and the surface is now smooth, with little else upon it but the fibrous

roots of the whorle bushes. The peat is found about six inches below the surface, and is said to vary from three to ten feet in depth. While lying in the bed it resembles common swamp muck—is more compact, and of a slightly reddish cast. When dried it is hard and friable, lighter colored than common charcoal, receives a polish, and burns with a steady clear flame.

I understand that a company has been formed who are to commence digging it next spring. It will undoubtedly be a valuable acquisition to this part of the state.

Yours, &c.,

MYRON ADAMS.

East Bloomfield, N. Y. 1842.

Remarks on the above, and on Redemption of Peat Meadows.—There cannot be much doubt that the substance our respected correspondent has described is peat; and the reddish coloring matter mentioned comes from iron mixed with it. A company he says is formed to commence digging it the next spring; but what is the specific object of this company, whether manure or fuel, is not said.

As a manure, peat forms a valuable ingredient in compost; being formed wholly of decayed vegetable matter, it is well adapted to restore to the soil the element, which cultivation exhausts. It requires, however, decomposition or disintegration before it is in a condition to apply to the ground. Lord Meadowbank's process for its reduction, of which so much is said in English agricultural works, consisted in forming a heap of peat with intervening layers of horse manure, which, taken green from the stables, soon produced heat enough to reduce the peat. Lime is recommended by Dr. Jackson, for the same purpose, but it must be quick lime. Dr. Dana recommends ashes, of the superior advantages of which we have no doubt. Peat likewise, the coarser kinds especially, may be advantageously thrown into the bog-eyes, where the bogs will soon reduce and intermix it with other substances; and it may with particular advantage be thrown into a barn cellar where the bogs have access, and where, if the manure from the horse stable is likewise deposited, the peat will act as a most useful absorbent; and the whole contents be made valuable. In many cases what is called black muck, is composed like peat of decayed vegetation, and seems to be peat in an incipient state. Do the farmers of Ontario county require this for a manure? We had supposed not; but our information is of necessity extremely imperfect. While they have vast amounts of wheat straw, and spent ashes lies untouched in large heaps at the potash establishments, and plaster works its magical effects among them, and clover affords its enriching nutriment, and their flocks of sheep are numerous, we had supposed, on their new and unexhausted soil, they would require few additional materials for manure.

As fuel, peat is highly valuable, where better substances cannot be had; but who would think of using peat where the best of rock maple and beech and hickory can be had for two dollars per cord? The odor of burning peat is offensive to most people; its ashes are very light and fill the house with dirt; and the trouble of digging and drying and carting is a good deal more than that of getting wood, and occurs at a season of the year when time is worth much more to the farmer than in the season of getting wood. We might be driven to use a peat fire by necessity, but was should never go to it from choice. It has, however, one great advantage; a block of peat kindled and raked up in the ashes will keep alive for a week.

If our friends, however, choose to use it for fuel, they will allow us to give them one word of advice as to curing it. In general, this is done by piling it in stacks crosswise on the margin of the meadow. Here it must remain sometime; and, if the season prove wet, it will be a long time before it will be ready for

being boused. The best pest we have ever seen has been cured in this way. After being dug, let it lie long enough upon the ground to become drained, and then let it be carried home and piled up in a shed, where, while it is protected from the rain, there is a thorough circulation of air round and among every part of the heap. This is much the least troublesome way of curing it; and the pest is heavier and will give more heat than when dried in the usual way in stacks on the field.

Our friends, however, may, we think, if we understand its condition, appropriate their peat meadow to a much better purpose, than that of either manure or fuel. Let them ditch and drain it thoroughly, or at least so as to reduce the water eighteen inches below the surface; then let them pare and burn the sods, at such a time that the meadow itself will not take fire; spread the ashes; put on a good dressing of compost, half loam and half manure, well mixed, and sow liberally of hard-grass, red-top, and clover. Or if they prefer a less expensive process, let them ditch and drain their meadow as above; clean away the rubbish with a stiff harrow or drag; and carry on, at a season when they can get on to the meadow with a team, good loam and sand, and spread to the thickness of two or three inches, and then sow grass seed as above. Or otherwise before the frost is entirely out, and when they can turn over the surface to the depth of four or five inches, let this be done carefully, inverting every sod, and then let a dressing of mixed manure be applied, the land sowed with grass seed as above advised, and rolled. The most thorough way of doing the business is undoubtedly the best. By this management, this land may be brought into most productive grass land, yielding, as we have repeatedly known, three and four tons to the acre. After three or four years a compact sward is formed, when it may be ploughed and cultivated with common crops. Within our own experience it has produced the best of rye, corn and oats. In Ireland, great improvements have been made in this way, and near Liverpool portions of Chat Moss have been redeemed in a similar mode under the direction of Mr. Reid. We regret that we have not at hand the means of stating the process of Mr. Reid and the results, but this we shall be able to do hereafter. The crops of wheat obtained on land redeemed in this way, were most remarkable. Much of this description of land has been recovered and improved in Massachusetts, of which we propose shortly to give a full account.

"Black Gum"—Bowlders—Mediterranean Wheat—Peach Buds.

[In a letter from Cayuga County.]

BLACK GUM.—On a late journey to Auburn, I observed plum trees in great numbers along the road, tricked out in all the finery of "black gum"; and I was rather gratified to see the progress it had made.

Rejoicing at the misfortunes of others? No—far from it; but the trees must soon die in the hands of their present owners, who take no care of them; and the sooner they die, the better.

Is that so? Yes, and I can prove it. Every one of these trees is a nursery of insects, to annoy the trees of their industrious neighbors; and so long as such nuisances exist, so long must every pomologist within a mile or two of them be in a state of continued watchfulness or warfare. When all these worthless trees perish, however, the insect, having no place to breed in, and nothing to live on, must perish too; and then—the dark cloud having passed over—plum trees may grow and flourish as they did ten years ago.

Although we have given line upon line, and precept upon precept, yet it may be proper to mention the remedy for this "evil" once more. Possibly some landed proprietor may be awakened up, and induced to exert himself as it were at the eleventh hour.

Cut off all these black bunches or excrescences, which probably at this season, however, contain no insects, for their removal is necessary to enable us to detect the *new* bunches which will form late in spring or early in summer. The latter, containing the worms or larvae, should be carefully burnt as soon as they are discovered; but to prune the tree thoroughly, removing all surplus wood, and leaving the branches so open that any new excrescences may be detected at a glance, would save much time and trouble.

BOWLDERS.—Every traveller in this part of the State, whose perceptive faculties are well developed, must have observed that fragments of rocks, varying greatly in size, are scattered over the land; and that most of them differ entirely from the rocks which occur in regular strata.

Now how did those bowlders get there? This question would be answered very differently by different persons.

Some believe that *stones grow*; and that the pebble of to-day may become a large rock in future years. In other words, that they grow as naturally as pumpkins. Nobody, however, has discovered the stem that rocks grow on; nor the veins or pores through which their nutriment circulates. *Animal life* and *vegetable life* are familiar terms; but *mineral life* would be something new in the language of naturalists.

Other people who (like the former) have not studied causes and effects, quietly conclude that those fragments have *always been there*; and see no reason to wonder at their appearance. It has been observed, however, that nearly all the rocky strata in Western New York abound with the remains of animals that once existed; and which could live buried deep in the earth no more than a horse or a cow could live there. When alive they were at the surface of the ground, though that surface was probably at the bottom of the sea; but certainly they never lived with those rocks on their heads; and if we may judge from the plainest analogy, every one of those bowlders, lies directly over the remains of some animal.

It will be ample to conclude, therefore, that there was a time when these rocks were not in their present positions; and the question may properly recur, how did they 'get there'? In a late lecture on Geology, delivered by Professor Silliman in the city of New York (as reported in the Tribune), I find the following remarks on the *transportation of bowlders by means of floating ice*:

"It is not at all necessary to draw upon the imagination to understand this fact; for it is a matter of observation that ice-islands of vast magnitude are frequently torn away from their beds and floated through Hudson's and Baffin's Bay to more southern regions. I have seen myself ice-islands floating through the ocean, towering from one hundred and fifty to two hundred feet above the surface of the sea; and as we know that floating ice never shows above the surface more than one eighth of its bulk, we may reasonably conclude that islands of sixteen hundred feet in thickness frequently float from the Arctic regions to more southern climes. It is easy to see then, that these islands are capable of transporting immense loads of rock, far more heavy than the largest ships of war; and it is obvious that when these islands float into warmer regions, they must melt and drop their load. Thus the rocks which come from the most northern regions are deposited in the bottom of the southern seas. These masses, transported thus, may be seen off the West Coast of South America, and at the island of Chiloe. The process has long been going on, and will be in progress forever."

These remarks present a very interesting view of the subject, and there can be no doubt of their cor-

rectness; but they fail to cover the whole ground. The bowlders in this part of the country, generally show the effects of attrition; and where they are derived from rocky strata on this side of Lake Ontario, some estimate may be made of the distance that they traveled, from their change of form—the nearer to their native beds, the more angular—the further, the more rounded and worn. Fifty miles of rolling and grinding have effected great changes; but fifty miles of navigation would produce no such results. I must, therefore, conclude that our bowlders generally traveled by land.

MEDITERRANEAN WHEAT.—A letter recently recently received from a (*fourth*) correspondent near Philadelphia, contains the kind and liberal offer of a barrel of the *Mediterranean Wheat* for sowing next fall, with the following additional information:

"Its character here is rising, improving as it becomes acclimated. We have not yet tried it for bread, but [A. & B.] who are remarkable for having very nice bread, say that it is excellent; and that the flour is more like what they used to have in old times."

It may be remembered by some of your readers that this wheat is exempt from rust, and from the attacks of the Hessian fly.

PEACH BUDS.—In my letter contained in the first number of the current volume, I mentioned that the peach buds had swelled; and that unless the winter should prove unusually mild, they would be likely to perish. Well, the winter has been unusually mild—they remain uninjured; and the lateness of the season (2 mo. 20.) encourages the hope that the danger from intense cold is nearly over.

The Principal of the Cayuga Academy at Aurora, has politely furnished me with observations made at that place, on the temperature. The greatest cold was on the morning of the 14th of the first month when the mercury stood at 6° above zero; but further from the lake and at a greater elevation; it was doubtless colder. Between Aurora and this place, however, I think the difference would not be more than two or three degrees, so that with us there must be more than thirty degrees of frost to destroy the blossom buds of the peach when they are swelled. The least buds are much harder.

Ontario Agricultural Society.

This Society held their usual meeting at Canandaigua on the 8th ult. So inclement a day has hardly been experienced this winter; and the roads were extremely bad. The attendance of Farmers was good but the show of agricultural products and stock was very small. It could not have been expected that the animals, unless they had a good deal more public spirit than their owners, would consent to be tied to a stake and shown upon the common on such a day as that, for the gratification of public curiosity or their own vanity. We found very few of the farmers willing to "take airs" upon themselves on the occasion and who did not prefer looking at a good maple fire to looking at a fat ox, though they seemed to have no objection to the latter after he had been at the fire like wise. This season of the year in our climate, is very unsuitable for a cattle show.

The premiums were awarded as follows:

To Pitt May, of Hopewell, for the best two acres of Wheat, \$10. The yield was 37½ bushels per acre
To Jesse H. Bannell, of Canandaigua, second best ditto, \$7. 28 bushels.
To Eph. W. Cleveland, of Naples, for the best field of Corn, not less than one acre, \$7. 82½ bushels per acre.
To Royal A. Andrews, Bristol, for second best do \$5. 70.21 bushels per acre.
To Bani Bradley, of E. Bloomfield, third do. \$3. 43.61 bushels per acre.
To John Raines, Canandaigua, for the best field of Barley, no less than one acre, \$5. 41½ bushels.

To Joel S. Hart, Hopewell, second best do. \$3.
To Bani Bradley, E. Bloomfield, for the best field of
Oats, \$5. 3½ bushels per acre.
To Myron Adams, E. Bloomfield, second do. \$3.--
69.12 bushels.

To Joseph Blodget, Gorham, for the best acre of
Peas, \$5. 47.35 bushels.

To Wm. Bryant, Manchester, for the best field of
Potatoes, \$5. 100 bushels on half an acre.

To Chas. B. Meek, Canandaigua, for best Rye Biscuits,
\$5.--30 tons. Same, \$3 for second best, 22 tons.
Same, \$5, for best Mangel Wurzel--15 tons on
153 rods.

To Chas. Godfrey, Seneca, for best yoke of Fat Oxen,
\$7.

To Myron Adams, East Bloomfield, for the best fat-
ted Cow, \$5.

To Geo. Cayward, Seneca, for second best do. \$3.
To Cassius Osborn, Gorham, third do. \$2.

To Myron Adams, E. Bloomfield, for best fat Steer,
\$5.

To Sam. Greenleaf, Canandaigua, second do. \$3.
To Chas. B. Meek, do third do. \$2.

To A. M. Bass, Hopewell, for the best fat Heifer,
\$5.

To John Biddle, Canandaigua, for best six Fatted
Sheep, \$5.

Mr. Godfrey's fat oxen, a cross with the Devon,
and Mr. Myron Adams' steer and cow, of Devon
blood, would have done honor to any show. Mr.
Cayward's cow was a very fat and heavy animal with-
out any pretensions to aristocratic blood, and certainly
none to symmetry or beauty.

Monroe County Agricultural Society.

At a meeting of the Monroe County Agricultural
Society, held at the Arcade, in the city of Rochester,
on the 19th day of February, 1842.

The meeting was organized and proceeded to the
election of officers for the ensuing year, when the
following persons were elected:

For President,

HENRY COLMAN, Rochester.

For Vice Presidents,

WILLIAM GARBUTT, Wheatland,

LYMAN B. LANGWORTHY, Greece,

WILLIAM C. CORNELL, Henrietta.

HENRY M. WARD, Recording Secretary.

M. B. BATHAM, Corresponding Secretary.

For Managers,

Rawson Harmon, Wheatland,

Nathaniel Hayward, Brighton,

Ass Rowe, Gre. ce.

Caleb K. Hobbie, Irondequoit,

E. H. Barnard, Mendon,

Jacob Swann, Chili,

Gideon Ramsdell, Perinton,

Miles Lawren, Ogden,

John H. Robinson, Henrietta,

Alfred Fitch, Riga,

Abel Baldwin, Clarkson,

F. T. Root, Sweden,

David M. Smith, Rush.

For Town Committees,

Wheatland--Jirah Blackmir, George Sheffer,
Samuel Wood.

Chili--William Pixley, John K. Valentine, John
Toller.

Riga--Dennis Church, Charles Tenney, John
Rowe.

Ogden--Oliver Day, Modad P. Parker, Jesse
Harron.

Sweden--S. D. Baldwin, George Allen, Hum-
phrey Palmer.

Clarkson--David Forsyth, Frederick F. Church,
Abel Baldwin.

Parma--L. W. Metcalf, Roswell Atchinson,
Abner Darling.

Greece--Hall Colby, Nicholas Reed, John Moxon.
Gates--Lyman Potter, Moses Dyer, Matthias
Garrett.

Brighton--Timothy Wallace, Romanta Hart,
Oliver Culver.

Henrietta--Matthias L. Angle, James Sperry,
Stephen Legett.

Rush--Thomas Wright, William M. Mott, Chas.
Chamberlin.

Mendon--Abner Cole, Benjamin Birdsall, Jr.,
Thomas Wilcox.

Pittsford--Alexander Voorhees, Ira Bellows, El-
eazer Sutherland.

Perinton.--Zerah Barr, A. Goodell, Elisha Ram-
sey.

Penfield--Elias Beech, Daniel Fuller, Samuel
Miller.

Webster--Bryan Woodhull, William Holt, Alphe-
us Crocker.

Irondequoit--Benjamin King, H. N. Langworthy,
Cummings.

Rochester--Alonso Frost, E. Darwin Smith, Na-
thaniel Ormer, Ansel Frost, George Whitney, Alex-
ander Keley, Patrick Barry.

On motion, it was Resolved, That measures be
taken by this Society for establishing an Agricultural
Museum in the city of Rochester, and that a commit-
tee of five be appointed to make inquiry respecting a
room for the purpose, and to send a petition to the
Governor and Legislature for a set of the specimens
of Natural History collected by the Geological Sur-
veyors, and to report at the next meeting of this Soci-
ety.

On motion of E. Darwin Smith, Resolved, That
the thanks of this Society be tendered to Lyman B.
Langworthy, for the able, diligent, and faithful atten-
tion to the duties of the office of President of this
Society for the last two years, during which he has
officially acted as such.

Adjourned to meet at the same place on the 17th of
March next, at 10 o'clock, A. M.

HENRY M. WARD, Rec. Sec.

The First Effects of the Bankrupt Law.

We are told by the New York papers that since
the operation of the Bankrupt Law, numbers in
that city have come forward to compromise with
their creditors who for years past have made no
effort to pay their debts. They now evidently
dread the searching operations of that Law.

The doctrine that when a man fails, he has more
money to expend in show and amusement, seems
now to be on the eve of an explosion. With pru-
dence and economy--hard times can neither affect
a farmer's independence, nor retard his mental
culture and intellectual pleasures.

In some of my former brief articles, I have en-
deavored to impress my rural friends, with the ne-
cessity of their predicating their future expendi-
tures and habits of living, upon that economical
scale, which the approaching low prices of agri-
cultural productions would soon render impera-
tively necessary to their comfort and independence.

Within the last few months wheat has fallen
from the price to which an infatuated speculation
had forced it, down to 87½ cents per bushel. In
its fall it has carried with it most of the millers
and speculators, together with several banks; so
that for some time to come farmers cannot expect
another inflation of prices, from a demand purely
speculative. Pork, which had last season touched
the lowest point in price ever before quoted in the
market, has now gone down so low as hardly to
cover the expense of barrel, salt, and freight from
the far West. Whiskey, owing in part to the
glorious temperance reform, has shared the same
fate. Indian Corn does better, owing to an im-
proved export demand for this grain. It would
seem that a kind providence has thus smiled upon
the legitimate uses of Indian corn, the moment
that man had ceased to pervert them, by "turn-
ing good to mischief!" Clover Seed, which was
supposed to be a very short crop, has, contrary to
all calculation, continued to decline in price until
its price has become merely nominal. Still, in the
midst of low prices, the independent farmer is
better off than most of the other classes of com-
munity. He has no rent to pay, no corporation
taxes to tease him weekly; so far as he is the
consumer of his own products, the price is of no
importance to him; in barter for cloth his wool is
worth as much as ever. Many of his other pro-
ducts are equally available in exchange for labor,
&c. He may not indulge in as many far fetched
luxuries, in all such imported fabrics as fashion

imposes; but his intellectual pleasures need not
be abridged on that account; as mental culture
depends on taste and enthusiasm, and not on mer-
etricious display, nor does it cost any thing but
time and study. The delightful study of nature's
laws, is in the way of the farmer's vocation and
daily calling; let him then, instead of repining at
low prices, hard times, and a lack of money, re-
flect that such privations are the only means to
bring back the nation's long lost health; that, al-
though the medicine is repulsive and exceeding
bitter, it is nevertheless indispensable to a perfect
convalescence. S. W.

Waterloo, Seneca Co. N. Y.

Grafting Cherry Trees;

A practice which has hitherto been attended with
some difficulty, inasmuch that inoculating has usu-
ally been substituted for it. In the spring of 1841,
we engrafted a few small trees by the following
process. It was in March, and rather a cool day,
so much so that a furnace of coals was necessary
to warm the wax. After sawing off the head of
the tree to within about six inches of the ground,
we took a sharp pen-knife and made incisions in
the bark, designed to be parallel and over the cleft
of the wood. The wood was then split and the
scions set in the usual way; after which I took a
fine piece of paper over which wax had been spread
and carefully applied over the wounded part. Over
this, wax may be again applied to keep it in place,
and over the whole we placed a ligature of India
rubber cut entire to keep the parts from extending
by the frost. W. B.

Mount Osceola, Feb., 1842.

A Treatise on Domestic Economy.

For the use of Young Ladies, at Home and at School.
By Miss Catharine E. Beecher,--late Principal of
the Hartford Female Seminary. Boston: Marsh,
Capen, Lyon and Webb.--1841.

This is a capital book; full of wise and useful ad-
vice, showing intelligent and exact observation, and
speaking often from experience. The objection we
have to the book is, that it contains a great deal too
much, being a sort of Encyclopedia of Agriculture,
Gardening, Horse-keeping, Health, Manners, &c.
It does not seem civil to complain of getting too much
for our money, but the book would be much more
read if it were smaller. We are not quite satisfied
with the copious darts, which Miss Beecher makes
upon other and contemporary writers. If they were
books of many years ago, out of print and unattain-
able, there might be reason for it; but there is no jus-
tice in plundering the baskets of those who are in the
market with ourselves. Fair play is a jewel, and this
lady has no occasion to shine in borrowed dresses.

Nor do we see the appropriateness in a book for
young ladies at school or at home, of treating of the
construction of barns and barn yards, cow keeping
and horse keeping; unless her book is specially de-
signed for some of the Dutch girls at the West, whom
we have seen more than once in the market driving
their teams loaded with wood. In New England we
have not yet quite got to that.

The book, however, is a good one, and we shall
enrich our columns with some useful extracts from it.
It must, we think, however, unless the author is five
lozen grove fault to Miss Beecher. We know but a
few good fellows who, if they knew what is good
for themselves, would at least try to put such a house-
keeper into her proper sphere, and compel her to joff
her maiden plumes.

Winter of 1841-2.

The winter just closed upon us, has been most re-
markable for its high temperature and the small
amount of snow, which has fallen. The wheat, as
far as we have seen it, looks well. It remains to be
seen what is the ultimate effect of such a season, upon
the crops of grass and grain. There is time for some
snow in March.

N. Y. State Agricultural Society Reports. (Concluded from our last.)

ON BUTTER.

The committee unanimously award the
1st premium, \$30, to J. T. Lansing of Watervliet.
2d " " 20, to W. Merrifield of Guiderland.
3d " " 10, to Charles Lyon of Ogdensburg.

MR. LANSING'S STATEMENT.

1. The number of cows ten.
2. Stabled through the inclement season; fed them from three to four times per day with good hay or green stalks; when near coming in, some oats, barley, or corn cracked. In summer, good pasture, with living water at all times, and plenty of salt.

3. Treatment of milk and cream before churning. Stir in the milk in tin pans; place them in a cool cellar for the cream to rise. When sufficiently risen, separate the cream from the milk; put it in stone jars, well prepared, before churning.

4. The mode of churning in summer.—Rinse the churn with cold water; turn in the cream, and add to each jar of cream put in churn one-fourth of the same quantity of cold water. The churn used is a patent one, moved by a hand crank, having paddles attached, and so constructed as to warm the milk, if too cold, with hot water, without mixing them together. The milk and cream receive the same treatment in winter as in summer; and in churning, use hot instead of cold water, if necessary.

5. Wash the butter with cold water till it shows no color of the milk, by the use of a ladle.

6. Use the best kind of Liverpool salt which the quantity varies according to the state in which the butter is taken from the churn—it soft, more, if hard, less, always taking the taste for the surest guide.—Add no saltpeper nor other substances.

7. The best time for churning is the morning, in hot weather, and to keep the butter cool till put in casks.

8. The best mode of preserving butter is in and through the summer and winter, is as follows:—The vessel is a stone jar, clean and sweet. The mode of putting it down is to put in a churning of butter, and put strong brine: let it remain on till the next churning is ready to put down, and so on till the jar is filled; then cover it over with fine salt, the same to remain on till used.

Watervliet, Jan., 1842. JACOB T. LANSING.

MR. MERRIFIELD'S STATEMENT.

Cows—Eight.

Kept.—In pasture, in summer; on hay, straw, and roots, in winter.

Milk strained into the pans, and placed in the cellar.

The cream only churned, in a Dutch churn.

Method of freeing the butter from the milk.—By pressure.

Salt used.—Liverpool salt, one ounce to the pound. Kept in the cellar, in summer, in wood.

In winter, our milk stands twelve hours; is then removed to the stove, and scalded over a slow fire to near boiling heat; the pans removed to the cellar to cool; the cream only churned.

Guiderland, Jan., 1842. WILLIAM MERRIFIELD.

MR. LYON'S STATEMENT.

TO THE COMMITTEE.—The tub of butter exhibited was manufactured without reference to this exhibition—in our ordinary way. My hours for milking are very regular. My dairy, numbers twenty cows, seven of which were milked for the first time this season. I fattened only six calves to the age of six weeks. The latter part of the winter and through the spring, my cows are fed about one peck of ruta baga each; salted once a week in winter, and twice in summer. Salting regularly, is essential, is conducive to good health; and tends to produce a uniformity in the quantity and improves the quality of the milk. The average product of my cows this season is 100 lbs. per cow, besides what is used in a family of from eight to ten persons. The shelves of my milk-house are so constructed as to admit a free circulation of air. My buildings do not require drains to my cellars. The milk is strained as soon as possible after milking, in tin pans, about three quarts to each pan; and stands until the milk is slightly turned, the time required depending on the weather.

Churning performed every day, (Sundays excepted.) When cows are regularly salted, I have never known an instance of any extreme difficulty in obtaining butter. After it is obtained, it is immediately taken from the buttermilk, all the milk worked off that is practicable at the time, salted to the taste, and

placed in a cool cellar until the next day, when the buttermilk is entirely worked out by the use of a ladle, and then packed solid in tubs.

The salt I use is rock salt. After the tub is filled, the butter is kept covered with brine sufficient to keep the air entirely excluded, especially that made during the warm part of the season. My tubs are placed in the coolest part of my cellar. Butter made and protected in this way, will keep sweet one, two, or three years.

CHAS. LYON.
Oreogathie, St. Lawrence Co., Jan., 1842.

REPORT ON CHEESE.

The Committee on Cheese report.

There were only five specimens on cheese presented for premium, that came within the rules of the Society. The cheese was generally of good quality, and creditable to the contributors and to the Society. The number of competitors was small, and a reflection on our dairy counties, which are so distinguished for the qualities of their cheese.

The specimen of D. Marvin was very good, and the committee had some hesitation in deciding the comparative excellence of this and that of H. & P. Allen of Duaneburgh, and finally decided in favor of the latter, as entitled to the Society's first premium of \$30, upon the fact that this was rather the most mild and uniform in taste and flavor.

Your committee award the second premium, of \$10, to D. Marvin of Cooperstown.

The other samples were very good, but were not of so even a quality, nor uniform in flavor; and as there was no entry for old cheese, that came within the rules of the Society, your committee recommend a gratuitous premium of \$8 to Phineas Hard of Le Ray, for a sample very fine, and deserving particular notice.

Your committee regret that in sections where so much good cheese is made, there should be so limited a number of competitors for the very liberal premiums offered. If the reward offered was the only motive for bringing forth these articles, the reason might be found in the little regard in the chaste minds of the community for that which many others have coveted; but as the great object of these exhibitions is to communicate and receive information on subjects of great interest to all, the grand and high principles which actuate worthy citizens, should lead them, by the exhibition of their own successful manufactures, to instruct, stimulate, and encourage those less informed than themselves.

A well managed dairy is one of the most valuable sources of a farmer's revenue. The product of a good cow, for a single season, in milk, butter, cheese, &c. may be estimated at more than thirty dollars.

We refer to the annexed statements of the competitors, whose success is the highest recommendation of the method pursued by them.

MESSRS. ALLEN'S STATEMENT.

Number of cows kept, eleven. Cheese made from two milkings, in the English manner; no addition made of cream. For a cheese of twenty pounds, a piece of rennet about two inches square is soaked about twelve hours in one pint of water. As rennets differ much in quality, enough should be used to coagulate the milk sufficiently in about forty minutes.—No salt is put into the cheese, nor any on the outside during the first six or eight hours it is being pressed; but a thin coat of fine Liverpool salt is kept on the outside during the remainder of the time it remains in press. The cheeses are pressed forty-eight hours under a weight of seven or eight cwt. Nothing more is required but to turn the cheeses once a day on the shelves.

H. & P. ALLEN.
Duaneburgh, Jan, 17, 1842.

MR. MARVIN'S STATEMENT.

The milk strained in large tubs over night; the cream stirred in milk, and in morning strained in same tub; milk heated to natural heat; add color and rennet; curd broke fine and whey off, and broke fine in hoop with fast bottom, and put in strainer; pressed twelve hours; then taken from hoop, and salt rubbed on the surface; then put in hoop, without strainer, and pressed forty eight hours; then put on tables, and salt rubbed on surface, and rennet in salt six days, and then weighing thirty pounds. The hoops have holes in the bottom; the crushings are saved, and set and churned, to grease the cheese. The above method is for making one cheese per day.

Cooperstown, January, 1842. DANIEL MARVIN.

MR. HARDY'S STATEMENT.

The number of cows kept is thirty-eight. Cheese

made from two milkings—no addition of cream.—The quantity of salt used was one ten-cupful to twenty pounds of curd, of common Onondaga salt. The rennet was prepared by soaking one rennet in a jar of five or six quarts, filled with salt and water. From one pint to one quart was used, according to the strength of the rennet, for a cheese of eighty or ninety pounds. The cheeses were pressed in a common wheel and lever press two days. The cheeses were taken from the press and rubbed with ammonia, soaked in strong ley, then rubbed with whey butter, and turned and rubbed daily through the season with the same.

PHILEAS HARDY.

Le Ray, Jefferson Co., Jan. 10, 1842.

REPORT ON WHEAT, RYE AND BARLEY.

The committee regret that they have been compelled to reject several applications for premiums, because the terms of the executive committee were not complied with. They regret it the more, because some of them would no doubt have received premiums—among whom were Elisha Pettibone, James Beatty, applicants for the premium on wheat, and Jay Pettibone for barley.

The first premium on wheat is awarded to George Scheffer of Wheatland, Monroe co. The amount raised was 300 bushels on 7 1-2 acres, averaging forty bushels to the acre.

The first premium on barley to John W. Turncliffe, Richfield, Oswego co., one acre yielding 53 1-4 bushels of barley. The whole expense of raising this acre of barley is estimated at \$12 50.

The committee regret exceedingly that in so large a grain growing State, so few men could be found who either deserved or were desirous of obtaining the premiums of the State Society.

REPORT ON CORN, OATS AND PEAS.

There were two applicants for premiums on corn, and your committee regret that the statements accompanying the applications were not more explicit, complying more strictly with the rules of the Society, as much useful information might be derived therefrom. They award the first premium of \$20 to William Ingalls of Volney, Oswego county, for raising 142 bushels of shelled corn on one acre of land.

And the second premium of \$10 to J. F. Osborn of Cayuga county, for raising 144 bushels weight 56 lbs. to the bushel, on one acre of land; but the mode of ascertaining the quantity was not wholly satisfactory to the committee.

There were five competitors for oats, all very highly deserving of commendation.

They award the first premium of \$15 to D. W. Weeks of Watertown, Jefferson co., for raising 113 1-2 bushels on one acre of land.

They award the second premium of \$8 to John S. Jones of East Bloomfield, Ontario co., for raising 102 1-2 bushels on one acre of land.

They recommend a premium of \$5 to Amos A. Egleston of Greenwich, Washington co., for the excellence of the specimen presented by him, weighing 42 lbs. to the bushel, it being also a large crop.

There were no applicants for peas.

The committee appointed to examine the beautiful production of art, called the *Amazon Bonnet*, exhibited to the Society by Messrs. Valentine & Eaton, No. 121 Water street, New-York, report:

That they called to their aid a number of intelligent ladies, by whose taste and superior judgment in these matters, they were controlled.

This specimen of ingenuity, combines great elegance and beauty with strength and durability. It is manufactured from the finest quality of *Manilla* grass. Six thousand five hundred fibres, woven together, will make about one hundred yards of braid, which quantity will make one of the finest class of bonnets. This material may be twisted into an endless variety of patterns, and is susceptible of any color or figure.—This bonnet can be taken apart, and cleaned with ease, and put together again, losing thereby none of its original beauty or value. Its texture and durability have never been equalled, and for beauty, it surpasses almost any thing of the kind. The material from which it is manufactured is imported, but is of small value compared with the labor in braiding the same. If it comes into general use, it will open a field of productive industry to many ingenious females and children of our populous towns. We commend this bonnet to the patronage of the American ladies. Benevolence to a large class of their own sex in destitute circumstances, should prompt them to encourage the production of an article that will afford employment, and consequently comfort to indigent but worthy females.

REPORT OF THE TREASURER, E. P. PRENTICE. The reports of the Society the last year, were as follows: Balance in treasury, at last meeting, \$36 87
From right life members, \$50 each, 400 00
Seven subscriptions, \$25 each, 175 00
Two " " \$20 each, 40 00
Eleven " " \$10 each, 110 00
Twenty-three " " \$5 each, 115 00
From members, and other sources, 442 82
From Comptroller of the State, 700 00

\$2,029 69
Paid premiums, expenses, &c, 1,065 46

\$961 23

From which is to be deducted about \$200 for premiums awarded, but not paid.

The treasurer also reported that a quarter of one Mr. Fuller's tax on, presented to the Society by Mr. Riser, had been added for \$24 97, which, added the above sum, would leave a balance in the treasury of about \$800, after the payment of all demands against the Society. The committee appointed recommending a place for holding the annual Show, after fixing Albany or its vicinity for 1842, recommend at the Show for 1843 be held at Rochester.

On motion of Dr. Goodsell, of Utica, Resolved, That this Society recommend to the anti agricultural societies to use their exertions to establish town societies.

On motion of J. B. Nott, Esq., Resolved, That a committee of five be appointed to report at the next meeting on the propriety of establishing an Agricultural Board for this State. [Committee—Messrs. NUTT, VAN BRUNEN, BELKMAN, DEXOW and VIELE.]

Amendments to the Constitution.

On motion of J. B. Nott, Esq., Resolved, That no article of the Constitution can be altered or amended, without a notice of being given one year before such alteration. Mr. FULLER gave notice that at the next annual meeting of the Society, a motion will be made to amend the Constitution, so that presidents of county agricultural societies shall be ex-officio members of the Executive Committee of the State Society. The Society then adjourned, sine die.

For the New Genesee Farmer

Farmers' Gardens.

What higher authority can we quote than a lady? Who has better taste, more refined sensibilities, a keener judgment or nicer observation, than the female part of community? Happening to meet one who possesses the excellencies of her sex in an eminent degree, the other day, we heard her remark that the farmer who failed of having a good garden, failed in economy, and not only that, but he was himself off from many of the comforts of life. Arguing from the practice of most farmers in our country, we must suppose they are ready to exclaim "this is a hard saying," but let them enjoy the comforts and luxuries of a good garden for one year, let them count the actual cost in labor and expense it requires, and give a careful credit to its proceeds, and if they do not find it the most profitable investment of their estates, we will—concede that their experience has been different from their own. Though our garden is done up in a fall way, yet we find it not only an invaluable appendage to our affairs, but with our present ideas on such things, one of absolute necessity; for we cannot forego the delicacies of the rich tomato, or the tender vegetable it affords in the hot summer days, any more than we can our daily bread. And the cauliflower, who that ever tasted of them would willingly suppose that a future season could pass without furnishing himself with an abundance. As many who profess to admire them do live, year after year, without making a single effort for their production. They are almost as easily raised as common cabbage. Like them, they should be sown for early use in a hot-bed, an article that every one who cultivates a small patch of earth, should prepare; for by sowing in them, a month or two weeks may, without diminishing in any way

from the general reign of cold weather, be added to our short summers. They may be got up very cheaply. One with half a dozen lights of glass will do to prove their utility, and these lights may be set in any old sash, or in a cheap frame, which any one gifted even with a small measure of mechanical skill, may manufacture in the leisure time of winter, and by so doing, heavier bars and frames may be made, than is usual in common sash, which will give them a firmness that their exposure requires. If cheapness is studied, the box may be made of slabs, with the edges squared so as to set close; on this, the sash should lie at an angle of about 45°. In our climate, the best location for the hot-bed is at the south end of a building, for there, the cold northerly winds are broken off and the sunbeams reflect, as well as fall directly upon it, thus proving that in cultivation of plants, as well as animals and intellects, reflection is as useful as more direct action.

But farmers who would have every part of their garden perfect, should have larger hot-beds than the one we have quoted or, perhaps, what would be better, have several of the size alluded to, for then different vegetables can be started at a distance from each other. These small ones may have, among other things, a hill of melons, or of the exotic squashes planted in the centre of them, if located in different parts of the garden; and when plants, like the cauliflower, tomato, or any of those designed for transplanting are removed, the ground, well fitted for their growth, remains for the nourishment of the vine. By having them in different parts of the garden in different years, it may be kept in a very rich condition, by the well rotted manure they contain, and which, by the second year becomes, through the fermentation of the first, free from the seeds of foul weeds, so very annoying in a garden. Hot-beds should be made in March, and covered in severe weather by an old rug.

W. B.

Mount Osceola, 1842.

Manure for Gardens.

We have tried a variety of kinds of manure for a garden, and these kinds in a variety of forms, and as far as our experience warrants an assertion in favor of any particular kind, we must give a decided preference to *scamp mud*, or muck. One argument in its favor is, that it seldom produces weeds. Another, that it contains so much vegetable matter in a decomposable state that it is easily brought to operate as the food of plants. It also, from the slowness of its decay, continues its effect longer than most other manures. Its cheapness also commends it, for all it costs is the mere getting it from the pond hole, which will be sure to fill its treasury before a new draft is necessary. In order to have it *prime*, it should be placed in a pile for a few days, and ashes or lime mixed with it, and subjected to workings until the lumps are all reduced, and the two simples thoroughly compounded. It may then be put, half a shovel full will answer, in the hill for melons, cucumbers and squash. For radishes and the like, we use it as a top dressing.

W. B.

Mount Osceola, Feb., 1842.

Advantages of the Climate of the United States over that of England.

Your correspondent, W. Garbutt of Wheatland, gives to the English farmer the advantage in length of season over the farmer of the United States, without even adverting to the very great advantage we have, in the superior stimulating power of our much warmer and more kindly season of vegetation. If by some change in the Solar System, the

power of terrestrial magnetism, or some involution in nature's course, the soil of England could be so far stimulated by the sun's rays as to produce Indian corn to perfection, should we any longer hear of her "starving population," reduced to live on the miserable bread made of damp mouldy grain? It is true that England has less severe cold weather and a shorter winter than we have; but look at the slow process of vegetation there as compared with that of the United States; her late harvest crowded into the short, cloudy, and even wet days of autumn, and it is not surprising that her corn is damp and mouldy. What would become of our ease-loving farmers if they had to encounter the cold, sour, wet climate, and slow vegetation of that country called merry, not sunny, England? Would they not be reduced from bacon and corn bread, to turnips and pea soup, from the delicious wheaten loaf and hot rolls, to oatcakes and potato broth?

Mr. Garbutt says that roots cannot be cultivated in this country to the same extent, *adventuringously*, as in England. Very true, but then does our Indian corn, that thrifty precocious king of edibles (it being both food and fodder, oil and sugar,) render the like extensive cultivation of roots unnecessary? But we deny that roots may not be as easily cultivated in the United States as in England. If our more sunny champaign country is not as well suited to the turnip and potato, as cool and misty England,—our early planted sugar beets never grew in greater perfection with us, than during the last summer, the hottest and driest season we have had in many years; and there is little doubt but that one acre of sugar beets is worth two acres of turnips.

We fully agree with Mr. Garbutt that it would be folly for our farmers to follow the rural economy of England in all its variety, but for very different reasons than a part of those set out in his otherwise interesting and well written article.

Waterloo, N. Y.

S. W.

From the Farmer's Monthly Visitor.

Great Yield of Potatoes.

In 1839, the late Major Caleb Shaw planted potatoes (the large round red) on several patches of ground in Suncoek village in the town of Pembroke; he planted them without assistance, and hoed them three times himself. They were planted in drills, one piece (cut) every ten inches, and when he dug them in the fall, they were weighed, and he proposed, from the result, the following questions to Hon. John Vose, then preceptor of Pembroke Academy. I find the questions and answers among some of his papers, and send them to you.

QUESTIONS.

1st portion, 165 square feet produced	126 pounds.
2d " " 147 " " "	138 " "
3d " " 18 feet square, " "	384 " "
4th " " 43 " " "	1435 " "

ANSWERS.

1st portion, per acre, 32,670 lbs.	605 bushels per acre.
2d " " 41,745 " "	773,055 " "
3d " " 51,626 2 3	956,349 " "
4th " " 38,906 " "	426,05 " "

The above results were brought about by Mr. Brown; of their accuracy, I have examined them, so as to be satisfied they are correct. I witnessed the progress of the growth of the potatoes, and the average weight of them was 54 pounds per bushel.

JOHN VOSE.

Typhus Fever.

It cannot be too widely known that nitrous acid gas possesses the property of destroying the contagion of the typhus fever, and certainly of preventing its spread. By the following simple method the gas may be produced at a very trifling expense.—Place a little powdered sulphate in a saucer, and pour on it as much oil of vitriol as will cover it; a copious discharge of acid gas will instantly take place, the quantity of which may be regulated by lessening or increasing the quantity of the materials.—*English paper.*

ROCHESTER, MARCH, 1842.

To Correspondents and Readers.

We cannot say with one man on receiving his friends that we have too much company for our chairs, but we sincerely regret that we have not chairs enough for our company.—Our limits and the late hour at which several communications were received compel us to postpone them until our next.

J. E. T.'s most welcome essay is in type.

C. N. B.'s valuable article on Winter Butter is in type.

J. W.'s excellent letter on the cultivation of Hemp will be in our next.

A "Subscriber's candid remarks on Improved Stock and the sound views of a "Friend of Improvement" are both received with respect.

Inquiries as to Gypsum, W. S. T. on Maple Sugar, a second letter from our friend Garbutt, our friend M.'s communication on choked cattle and Ruta Bege, valuable articles on Furin and Cottage Buildings, on Ploughing, on Protective Duties and Experiments in Farming, with various others, are of necessity laid by. But our friends may under these circumstances safely anticipate a choice sheet for April. Having said so much for ourselves in this number, we shall in our next yield the floor to our betters. In the mean time we beg our friends not to think we overlook or forget them. Let them turn in their grist; and so long as they give us clean grain, without any ches, or cockle or smut, as they have done, we'll do our best to turn out as good flour as any mill with the Rochester brand.

Broom Corn and Madder are waiting a place in our next.

Mr. Weddle's sale ought to command attention. There are some animals of extraordinary excellence.

Charms of Editorial Life.—Agricultural Inquiries.

January 22, 1842.

MR. COLMAN—

Sir—Having been somewhat acquainted with your views upon agriculture while you was in Massachusetts, and learning that you now stand at the helm of the Genesee Farmer, I think to extend my acquaintance with you, by pursuing your monthly periodical.

I have a few questions to lay before you, hoping for some valuable information.

My farm consists of about fifteen acres of a yellow loam mixed with sand. I have occupied it one season last, and find that rye, corn and potatoes, may be raised to good advantage; also carrots and sugar beets. But I am destitute of an orchard. My neighbors, who are in the same condition, tell me I must submit to it, which I am very unwilling to do. I therefore hope to learn from your paper your opinion, whether fruit trees will be likely to grow and flourish on my land—the best time for transplanting them—the manner in which it should be done, &c.—the treatment they should receive after, and the kind of manure most adapted to their growth.

I wish to know the best manner of curing hams, and of preserving beef from fall to spring, and for summer use.

Permit me to extend my inquiries a little farther. Be good enough to inform me of the best kinds of

swine, and manner of rearing pigs, and the treatment of sows suckling them. Also, how I can best keep bees through the winter and manage them in summer to get the best profit from them.

Yours respectfully,

Remarks.—Now here is a pretty kettle of fish to fry, from Connecticut river. What shall we do? The editor of the New England Farmer recently very politely remarked, that the late Agricultural Commissioner of Massachusetts 'could put more questions in a given time than any other man of his acquaintance.' But the late Agricultural Commissioner now acknowledges himself fairly beaten. Why could not our correspondent have put to us at once all the questions in the Westminster Assembly's Larger Catechism?—Why could he not have asked us a few more questions in natural history; as for example, why Niagara Falls do not stop running? How Connecticut river ever squeezed through Mount Holyoke and Mount Tom? How the trees ever got upon the top of Sugar Loaf? Why black-wooled sheep eat less than white? Whether flocks can be best caught in a common steel trap, or as the boys catch pigeons, by putting a little salt on their tails? and so on to the end of the chapter?

We should like to be near at hand when our friend desires a visit from his family physician; and should not be much surprised if some such application as this takes place. Doctor! when you are passing my house *just call in in a friendly way*, and see my wife, she has had now for some time a bad cough and pain in her side; and I want, at the same time, you should look at Nancy's finger, she has got, I believe, a felon upon it; and do ask for John and tell us how we shall remedy his club feet; and I hear, Doctor, that you can cure squint eyes, and I wish you would see what can be done for Tom, who seems always to be trying for his life to see whether his nose is on or off; and by the way, Doctor, if you have any genuine matter, I should be glad to have all the children vaccinated at the same time; and while you are there, Doctor, I wish you to look at my old horse, who seems to have a film over one of his eyes, and I wish to know how to get it off; and at the same time, I wish you to examine the milk of our heifer and let me know if you think there is any danger of our getting the milk sickness which I have read about in Indiana; and one other thing, Doctor, I came near forgetting, about which I very much want your advice, that is whether our baby's porridge should be heated in a tin dipper or an iron skillet.

All this, too, the man expects to get out of the Doctor without any fee, because he only asked the Doctor to call as a friend sometime when he should happen to be passing by the house.

Now we certainly mean nothing disrespectful to our good friend, but if it was the feather that broke the camel's back, what is to become of us when the whole bed, tick and all, is thrown upon ours? Perhaps we should save trouble in the case, were we to recommend to our correspondent to apply where he will find all the information he desires at his fingers' end. There are only twenty quarto volumes of the N. E. Farmer, let him read them; there are only eight volumes of the Albany Cultivator, let him read them; there are only four volumes of Hill's Family Visitor, he can read them as well as not; there is the old Genesee Farmer and the New Genesee Farmer; these, without reading the advertisements and the price currents, might stand him a little while; and then there is a little (not exactly pocket) volume, called London's Encyclopedia of Agriculture, which might occupy a few leisure evenings and assist him essentially in the management of his farm of fifteen acres.

But to be sober. Our friend we hope will pardon us for amusing ourselves at his expense. We really

have no serious objection to his inquiries. We like his curiosity. We will do every thing in our power to encourage and assist small as well as large farmers, and if he will have patience with us, we promise that every one of his questions shall have due attention, and so of as many more as he will put to us.

Withdrawal of Patronage.

We are honored with a letter of a different description, in which a respected friend complains that we admit the communications of a valued correspondent, S. W., whose views do not agree with his on the subject of protecting duties, nor indeed with our own.

But he says "he handed our January number to a brother farmer hoping to induce him to become a subscriber, but on returning it he objected on account of S. W.'s communication, saying 'that any paper advocating British interests, he was not disposed to patronize.' My views are the same, and I shall cease to be a subscriber if such articles are permitted to appear."

Now we beg to say confidentially and respectfully to our friend, that his threat has not scared us out of a night's sleep, and that whenever he thinks proper to withdraw his patronage from our humble publication, we shall be most happy to return his fifty cents. Sell our liberty of speech or discussion on any subject and all subjects we shall not, nor abate it one hair's breadth; if our friend wishes to know our creed on the subject of protecting Home Industry, he will find it in this very paper in the Resolutions of the Rochester meeting of the 16th ult. These we think he will pronounce orthodox.* But we are happy to hear the other side. Our great object is *truth*, and the only certain road to truth is free inquiry and discussion. We are willing, therefore, ourselves to hear and to let our readers hear what may be said on both sides of this great question.

We do not consider it at all a party question, but a great national question. We never will present it as a party question, or suffer, so far as depends on us, party considerations to be mingled with it. It is a political question we admit; and a question which concerns the farmers, the agricultural interest of the country certainly as much, perhaps more, than any other class in our community; and it is one of the most important questions in which they can take an interest.

Our paper shall never be made sectarian or party in any sense, even on the vexed question whether wheat can be changed into chess or chess into wheat, but it shall be open to the well expressed opinions of intelligent men, on any subject concerning directly or indirectly the agricultural interest. The communication signed S. W., in the January number, was admitted without our knowledge, and before we had reached Rochester. Yet upon review, we cannot see why it should have been excluded. Since the time we have received a communication from S. W. on another subject, evidently written with the feeling of a partizan, and reflecting upon one of the great parties of the country, which we notified him could not be admitted. Our columns shall not be stained by personalities or party reflections or discussions; but if we must lose our subscribers because we admit opinions or discussions, which do not accord with our own, we will bid every one of the 20,000 farewell before we will budge an inch. We have no fears but that truth and patriotism will here triumph; and we ask our good friend to review his decision and come out in his true character as the friend of universal liberty; and at once lend the aid of his good sense and his sound judgment, matured by much experience, in showing the farmers who read the New Genesee Farmer, how deeply concerned are the wool-growers

*These Resolutions are unavoidably deferred till our next

runners of our country in the protection of domestic industry. We have another word for his private ear: low happens it that a man brought up in a free country makes the most arbitrary of slave drivers whenever he goes South; or to come nearer home, how happens it that an old bachelor enjoying for forty years the largest liberty, should be disposed in any form, to encroach upon the liberty of other men?

Heartaches—perhaps.

We have another letter signed "Adolescents," inquiring what has become of Annette, and whether there is to be no answer to Helen's communication. Now what a luckless sight are we. Who is Annette? "Oh I where, and oh I where has this Dalcinea fled?" We would answer at once if we knew. And what is Helen's communication that she addressed to us? Was it in some tender strain, some gentle whisperings of kindness, some kind congratulations of some benevolent soul on our arrival in this Western Paradise? We have not seen it. Very likely our partner, a good-for-nothing celibate, when he took it from the Post Office, felt that it was warm, and pocketed it at once.

Great Sale of Blooded Stock.

The proprietor having disposed of his farm, will sell by Public Auction, at his residence in Greece, adjoining the Erie Canal, 6 miles west of Rochester, N. Y., on Tuesday, the 29th of March, 1842,

NINETY HEAD OF CATTLE, FOURTEEN HORSES, THREE HUNDRED SHEEP, FIFTY HOGS.

Comprising the whole of his full blooded and grade cattle, of the Improved Durham Short Horn breed, which includes the celebrated Bull "American Comet," who received the first premium at the exhibition of the Monroe Agricultural Society, 1841. Also the beautiful Cow, "Gazelle," 4 years old, now near calving, which has taken the premiums of the said Society for the last two years, with her two heifers, Hebe and Lucilla.

Also, three Stud Horses, sired by imported Turk. The Sheep are of the improved Leicester, embracing 14 Bucks of full blood, with a fine flock of ewes in lamb, and about 100 wethers. The hogs are Leicesters and Berkshires, all very superior.

The above are the finest selection of improved stock ever introduced into this country, and will afford an unusual opportunity to those who wish to improve their breed.

THOMAS WEDDLE.

Rochester, February 18th, 1842.

PEDIGREES OF CATTLE.

BULLS.

"AMERICAN COMET,"—white, calved April, 1838, is by Charles, alias Rover, (1816) dam Primrose, by Pioneer, (1321) gr dam, Prudence, by Candour, (107) gr gr dam by Ketton, (346) gr gr dam by Expectation, (247) gr gr gr dam by Col. Trotter's Magnum Bonum, (2882) gr gr gr gr dam by H. Chapman's Son of Pouch, (122) gr gr gr gr dam by Ralph Grimson's bull, by Charges, son of Favourite, (382) gr gr gr gr gr dam by son of Dalton Duke (18).

HEBE—calves 1840, by Am. Comet, dam Miss Grizzle, by Charles, alias Rover (1816).

CALVIN—roan, calved 1840, by Echo, own brother to Am. Comet, dam, Brilliant, from the Holland Company's Importation.

PHANTOM—light roan, calved 1840, by Echo, dam by Neptune, imported by T. Weddle.

WHITELOCK—5 years old, a Durham Short Horn.

HERO—white, calved 1841, by Am. Comet, dam, Comely, from Jenkin's stock.

TROTTER—roan, calved 1841, by Am. Comet, dam, Mountain Lass, by imported Neptune.

ECLIPSE—white, calved 1841, by Am. Comet, dam, Lilac, by Charles, alias Rover (1816).

PIZZA—light roan, calved 1841, by Am. Comet, dam, half blooded Durham.

FRONTIC—roan, calved 1841, by Am. Comet, dam, Peggy, by Roman, gr dam, imported Alderney.

COWS.

GAZELLE—roan, calved 1837, by Charles, alias Rover, (1816) dam, Crocus, by Romulus, (2563) gr dam, Prize, by Malbro, (1189) gr gr dam, Tulip, by Regent, (544) gr gr gr dam, Primrose, by North Star, (459) gr gr gr dam by R. Collins' White

Bull, gr gr gr gr gr dam, bred by Mr. R. Collins' Brampton County, Durham.

HEBE—white, calved 1840, by Comet, dam, Gazelle, by Rover, (1816) gr dam, Crocus, by Romulus, (2563) gr gr dam, Prize, by Malbro, (1189) &c.

LEICESTER—roan, calved 1841, by Am. Comet, dam, Gazelle, by Rover, gr dam, Crocus, by Romulus, (2563) gr gr dam, Prize, by Malbro, (1189) &c.

LILAC—roan, calved 1839, by Rover, dam, a pure Devon.

MILKMAID—red and white, calved 1839, by Leo, dam, a celebrated milker.

MARTHA—roan, calved 1837, by Rover, (1816) dam, a pure Devon.

MISS GRIZZLE—calved 1838, by Rover.

PEGGY—red and white, calved 1840, by Roman, dam, an imported Alderney.

FAIRY—roan, calved 1841, by Am. Comet.

MOUNTAIN LASS—calved 1839, by imported Neptune.

MATILDA—Full Blood, dam, imported Matilda.

CLARA—light roan, calved 1840, by Am. Comet, dam, a pure Devonshire cow.

CHARMING—roan, calved 1841, by Am. Comet, dam, Red Rose, a beautiful Devonshire cow.

MAY FLOWER—white, calved 1841, by Am. Comet, dam, Patty, by Rover, gr dam, imported Alderney.

BLOOM—red, calved 1840, by Roman, dam, Red Rose.

ORFAN—calved 1840, roan, by Roman, dam, Prudence, by Rover.

FANCY—roan, calved 1842, by Am. Comet, dam, Miss Whitefoot, by Roman.

GAILY—roan, calved 1842, by Am. Comet, dam, Red Rose.

DUTCH—white, calved 1842, by Am. Comet, dam, Mardie, by Rover.

JANNETT—white, calved 1842, by Am. Comet, dam, Mountain Lass, by imported Neptune.

GEY—roan, calved 1841, by Am. Comet, dam, Brilliant, from the Holland Company's Importation.

LOVELY—roan, calved 1838, by imported Neptune.

CLOPATRA—a Durham Short Horn, of superior milking qualities.

MOSS ROSE—roan, calved 1840, by Am. Comet, dam, Holderness.

Also, thirty Milch Cows, two yoke of Working Cattle, several young steers, and a number of half blooded Durham Heifers, of a very superior description.

|| A convenient credit will be given to purchasers.

Weighing Machine.

In a late number of this Journal some remarks were made on the importance of the frequent and regular weighing of domestic animals, to determine the best food and management for them. Machines of large size, such as for weighing loads of hay, large cattle, &c. are costly; and for smaller objects, as calves, sheep, and pigs, a cheap and good contrivance is represented in the annexed figure. It consists of merely a steel-yard, with the hooks removed, so that it may be suspended to the cross beam of the frame and not twist to one side, and a light wooden cage, for containing the animal, suspended beneath. One side of this wooden cage opens as a gate, and the animal may be either driven in or decoyed by food. If the frame cannot be so suspended as not to turn or twist, the upright posts of the frame should be so far asunder as not to touch the corners of the cage. With a large steel-yard, and a high frame to prevent the floor of the cage from being thrown too much in an inclined position

when the animal is not precisely in the centre, cattle of several hundred weight may be weighed. In the latter case however, it is better to have a strong lever, for elevating the cage, resting on a fulcrum near the upper end of one of the posts, and attached by a hinge joint to the extremity of the iron rod which passes through the cross beam. This lever may be removed when not in use, and the machine be placed under shelter from the weather. In weighing smaller animals, the lever may be dispensed with, provided the cage is several inches from the ground, the animal being made to enter while the open side touches the ground by a prop placed under the opposite side.

Such machines are not only of great value whenever purchases or sales are made, but still of greater, in determining the best modes of feeding and fattening, which indeed constitutes a very large part and often the greatest part of the expenses and profits of farming.

J. J. T.

Laying-out Farms.

In a late number of this paper, I offered some remarks on laying-out farms, and I propose occasionally to give some illustrations of the remarks there made. The annexed figure represents a farm of the simplest kind—a right angled parallelogram, where the land is nearly level—a form which very often occurs. It lies on one side of the public road, the sides of which are planted with forest trees. The first enclosure in the middle, has the dwelling-house nearly in its centre, and is planted with trees, for the sake of shade, ornament, and domestic attraction and enjoyment;—these trees are not planted "all in a row," but in the graceful and picturesque manner which distinguishes a beautiful natural landscape. Back of the house, is the barn, yard, and other out-buildings. On one side, are the fruit, kitchen, and flower gardens, the lot containing them being of an oblong form, for the more convenient separation of portions of the fruit garden or inclosing pigs, the sovereign remedy for the attacks of the curculio. The orchard may occupy either or both of the lots on each side of the house. The remainder of the farm is divided into fields nearly square, each one of which should be entered by a good, easy-swinging gate, from the lane which runs through the middle of the farm. The number of fields may be increased by making them narrower, without at all changing the position of the land. No farm over sixty acres, except it be of some unusual nature, should be divided into less than ten fields, as the importance of good rotation, and a full command of those fields at all times, and protection from the inroads of cattle, is far more than the expense of additional fences, or the land occupied by them.

The importance of a good lane, must be obvious to every farmer; many, being destitute, are obliged to draw their grain, hay, roots, manure, fire-wood, &c. over ploughed fields to the great fatigue of the teams, or over wheat fields destroying the crop, or over meadows cutting up the grass, or through pastures destroying the turf, all at an unnecessary expense of many hard-earned dollars a year. A good lane, made level by working down asperities, and rendered hard by gravelling or otherwise, would at once obviate these difficulties; and the trouble and vexation often experienced in driving ungovernable cattle and carts from one field to another, to the great detriment of the intermediate crop, would be entirely avoided.

J. J. T.

Silk Culture in New England. From Colman's Fourth Report.

I have the greatest pleasure in laying before my readers the annexed communications on the culture of silk, from my respected friend JAMES DEANE, M. D., of Greenfield, Mass.

They are exact, perspicuous, direct, and conclusive. It would be difficult to ask more in order to determine the question of the profit and success of this branch of domestic economy or household industry, if so it may be called. I cannot persuade myself that, now the proxysm of the multicausal insanity is over, they will not attract that attention from the farmers, which their intrinsic importance claims; and from the admirable manner in which they are drawn up, they cannot fail to be read with interest. I commend them especially to the farmers' wives and daughters, if I am not presuming too much in thinking they will honor any portion of my pages with a perusal. Will not they take an interest in the history of the wonderful and disinterested labors of those humble operatives, to whom they owe so much that is useful and beautiful, ornamental to their persons and gratifying to their taste,—those delicate and exquisite fabrics which were once the exclusive property of the palace, but are now within the reach of the humblest cottager?

MR. COLMAN.—

DEAR SIR:—The past summer, remarkable for the duration and uniformity of its high temperature, has been favorable to the cultivation of the mulberry tree, but from causes not sufficiently investigated, the rearing of silk worms has been attended, all over the country, with a succession of mishaps and disasters. The larvae composing my own stock were perfectly healthy, and commenced winning their cocoons on the twenty-eighth day, and as in the experiment I deem myself to have been successful, it is with true pleasure that I am enabled to present you a detailed statement of operations, together with some reflections naturally suggested by an acquaintance with this great subject.

There are several absolute changes in the life of the precious silk worm, which require for their complete development just one year, and as each change is regulated by peculiar principles, a thorough understanding of them all is essential to the success of those who undertake its artificial management. These changes embrace four distinct periods, the last terminating where the first began, to wit: the quiescent state, or that of the egg; the state of the larva, or of nutrition and the formation of the cocoon; the chrysalis state, or that intervening between the worm and moth; and finally the state of the moth, or that of reproduction. The so divisions are natural boundaries, and they cannot be too well understood.

The period occupied by the egg is about ten months, and when left to the action of natural causes, terminates in the spontaneous production of the young in aet, reciprocally with the first growth of its appropriate plant, when spring has far advanced. But to render exotic mulberry which have been retarded by annual transplantation, available, it has been necessary to retard in a corresponding degree the hatching of the egg. This can only be accomplished by subjecting it to the continued action of low temperature, somewhere between the freezing point and the 45° of the thermometer. This state should commence before the egg has felt the slight influence of the vernal heat, and the method I adopt is to deposit early in March in a tin box, containing the eggs, in contact with ice, and so keep them until wanted. In this way they have been known to keep two years and hatch well.

The eggs employed in my experiment were removed from the ice-house on the 29th day of July, and as an intermediate state between a low and high degree of temperature, they were placed in a cool cellar for a few days, and then subjected to the

TEMPERATURE OF THE HATCHING-ROOM.

1st day,	2d day,	3d day,	4th day,	5th day,	6th day,
72°	73°	73°	74°	73° to 74°	76° to 78°
7th day,	8th day,	9th day,	10th day,	11th day,	
74° to 76°	76° to 78°	75° to 78°	75° to 78°	76° to 78°	

Nearly the entire number hatched vigorously on the tenth and eleventh days, and all others were rejected. It will be noticed that the temperature was gradually elevated about one degree each day during the hatching process, and was maintained as nearly as possible to 77° during the subsequent feeding state, the essential features of which are presented in the following table.

Days of hatching.	Age of the worms.	Feeding state.	No. of worms.	Splice.	Age, out of.	REMARKS.
1 Aug. 3.	1st day of 1st age.	76° to 80°	12	5 feet.	2 hours.	Leaves chopped fine.
2 " 4.	" "	76 to 82	12	" "	do	" "
3 " 5.	" "	78 to 82	12	" "	do	" "
4 " 6.	" "	76 to 81	12	" "	do	Weather hot, with frequent thunder showers and a rain storm. Temperature occasionally regulated by stove.
5 " 7.	" "	74 to 80	12	" "	do	" "
6 " 8.	1st day of 2d age.	77 to 79	12	5 lbs.	4 hours.	Feed once during each night.
7 " 9.	" "	73 to 78	12	" "	do	" "
8 " 10.	" "	73 to 78	12	" "	do	" "
9 " 11.	" "	74 to 80	12	" "	do	" "
10 " 12.	" "	76 to 81	12	" "	do	" "
11 " 13.	" "	76 to 80	12	" "	do	" "
12 " 14.	1st day of 3d age.	77 to 82	12	5 lbs.	5 hours.	No. of worms 29,000. (Specimens)
13 " 15.	" "	77 to 82	12	" "	do	Weight of leaves, 1333 lbs.
14 " 16.	" "	77 to 82	12	" "	do	Weight of cocoons, 100 lbs. (chrysalis not stifled.)
15 " 17.	" "	77 to 82	12	" "	do	" "
16 " 18.	" "	77 to 82	12	" "	do	" "
17 " 19.	" "	77 to 82	12	" "	do	" "
18 " 20.	1st day of 4th age.	76 to 82	12	5 lbs.	6 hours.	Aggregate of time employed, 16 days—12 hours to the day.
19 " 21.	" "	76 to 82	12	" "	do	" "
20 " 22.	" "	76 to 82	12	" "	do	" "
21 " 23.	" "	76 to 82	12	" "	do	" "
22 " 24.	" "	76 to 82	12	" "	do	" "
23 " 25.	" "	76 to 82	12	" "	do	" "
24 " 26.	1st day of 5th age.	75 to 79	12	5 lbs.	one day.	" "
25 " 27.	" "	75 to 79	12	" "	do	" "
26 " 28.	" "	75 to 79	12	" "	do	" "
27 " 29.	" "	75 to 79	12	" "	do	" "
28 " 30.	" "	75 to 79	12	" "	do	" "
29 " 31.	" "	75 to 79	12	" "	do	" "
30 " 32.	" "	75 to 79	12	" "	do	" "
31 " 33.	" "	75 to 79	12	" "	do	" "
32 " 34.	" "	75 to 79	12	" "	do	" "

The silk worm being a cold blooded insect, receiving its temperature from the atmosphere, the necessity of keeping up a suitable degree of warmth will at once be perceived. The degree of temperature has been found by experience to be not far from the numbers indicated in the table, and it must be maintained not only through the feeding and spinning state, but also through those of the chrysalis and moth. It is indispensable, for in all the mysterious changes of the silk worm heat is the exciting agent; it is nearly in a state of torpor between 50° and 60°; yet it will move, but the time required will be twice as long, and the amount of silk not half so much, as when stimulated by a congenial degree of heat. Near the temperature of 77°, under active management, it completes its feeding state in 24 to 33 days, its spinning state in 5 or 6 more; it is a chrysalis about two weeks, and a moth one, during which time the sexes unite, and the female laying two or three hundred eggs, the circle of transformation is for the first time broken by death.

French writers, as I put an ounce of eggs to contain 40,000, but from numerous calculations I have never found the number to exceed 25,000. In this experiment I hatched an ounce, and the number of worms was not greater than set down in the table. The novice is always over estimating numbers. I sified the chrysalis with empor, and approve of the method as being cheap, expeditious, and perfectly efficacious, and at the same time not hardening the gum of the cocoon, which consequently reels with uninterrupted freedom. Miss Burton, who reeled my silk excellently, preferred cocoons treated with empor to those not stifled, because the dead chrysalides gave her much less annoyance in the heated water of the

basin. Reeling silk is a beautiful process that never fails to excite admiration, yet it is accomplished with ease, and with a little practice and steady perseverance, a young woman will reel a bushel of cocoons, yielding a pound or more of silk, in a day. The art is not however, yet carried to such perfection as to enable us to make the most of our materials, for all but expert reelers waste a considerable portion.

The actual amount of labor required in the first ages of the silk worm is very small, it is an agreeable noime. But when immense numbers pass into the fifth age, the labor, difficulties and cares become great and incessantly greater, and for the first time we are sensible of the enormous service which the establishment demands. Then we discover the obstacle, and it is like a mountain; we suddenly find ourselves surrounded by myriads of voracious insects that double their dimensions daily. Dirt and filth rapidly accumulate, signs of putrescent decomposition begin to appear, the weather is perhaps moist and sultry, and finally we perceive indications of disease and confusion. These considerations teach us the necessity of preparation, and of perfecting our system with prudent foresight.

The sudden and enormous demand of labor in the fifth age, is the great barrier to an unlimited production of silk. It is a great degree prohibits the application of capital, and the culture of silk naturally becomes an incidental branch of agriculture. Whoever discovers the method of dispensing with the tedious labor of this age, will confer everlasting obligations upon his country. That it will be systematized, and even in a great degree abolished, I think no one who is acquainted with the subject can reasonably doubt.

We have recently heard much complaint of Onondaga fine salt. Hams, after being five weeks immersed in strong pickle, were found to be fresh in the centre. Lime is often used by the salt boilers to discolor the sulphate of iron contained in the brine; this enables them to do without *bittern* pans, which are used to take out from the bottom of the kettle the red sulphate and also the ochereous substances deposited by the brine; this lime or the other precipitates, form a coating on the salted meat and prevent the thorough absorption of salt. Hence the frequent complaints of spoiled meat, when salted with Onondaga fine salt. We would advise all those who have old brine, to scald it and skim it, if not sour; if there is no blood in the pickle, a little fresh blood will cleanse it thoroughly, and render the brine pure, strong, and *caustick*. S. W.

Queries to a Terrified Editor.

We had supposed ourselves fairly out of the woods, when we replied to our Connecticut River friend's queries, varied and variegated as they were; but alas! how vain is all human confidence! We have heard of a man being in a peck of troubles, which has been ordinarily considered as the *extreme* of human affliction; but who ever heard of a lurch coming at once? We are reminded rather too seriously of the poor Frenchman who fell overboard, before he had quite learnt the force of the English auxiliary verb; "I *will* be drowned, said the poor dog, and *nobody shall* help me." Now look at the list honestly made up!

1. How shall we prevent gooseberries from moulding? Move the bushes once in three years, and grow them on a single stock.

2. Will my soil do for hemp, or shall I raise broom corn, and how shall I raise hemp, and how shall I raise broom corn? From a noble fellow who never chooses to dine at a public house at another man's expense. Answer next month.

3. How will you kill Canada thistles? Two years careful planting and hoeing, and persuading your neighbors to do as they would be done by.

4. Can you sell my Berkshire pig? Not without a description. What are their developments?

5. Do let us know how you cure the measles in swine? Brimstone and charcoal frequently, before and after they get the disease.

6. Give us a title on Horticulture. What is the best time and mode of transplanting fruit trees?—What are the best kinds of fruit trees; of apples; of pears; and what are the best modern treatises on Horticulture, and where can they be found? Call at M. B. Bateham's store, Rochester. See advertisement.

7. What is the best plan of a Hot-air Furnace? * what machine will give the most heat with the least wood; what would it cost at Chicago or St. Louis? The tight-iron stove or Arnot's patent. Can't answer the last query any more than the question debated before the London Club—How far it was from the 1st of August to the foot of Westminster Bridge?

8. "On a farm of 250 acres, what is the most profitable husbandry? How must I commence? How many sheep and swine, &c., must I buy, and what are the best kinds? How many cows and what breeds? How many teams, and whether oxen or horses, must I keep? How many hands must I employ to do the labor, as I do not expect to work myself? How many acres of wheat must I sow annually? and what quantities and kinds of spring grain? and what varieties of grass for hay and pasture, and what number of acres of each will be necessary for the stock recommended? and lastly, what amount of profit may I reasonably expect annually, if I superintend it faithfully and judiciously?" Here's a smasher for you! "Yours most truly," with a witness; why didn't he say yours till death us do part." This is undoubtedly a twin brother of our Connecticut River friend.

9. Will henlock unshes given to sheep, cause the ewes to drop their lambs? Don't know. Where can subsoil ploughs be had and what is their price? At Worcester and Boston; price reasonable. Once more, could not one of your mechanical friends contrive a small wind-mill?

In respect to the last matter, we have no question of the talent of the Yankees, as we saw lately a picture of a renovating mill for grinding over old people, operating in the most interesting manner, an old decrepit woman just dropping into the hopper, all gone but her feet and her blue woollen stockings lately footed, and coming out at the bottom a charming lass of blooming seventeen.

10. Another friend, who signs himself Plato, the

old original no doubt, just coming round as he predicted, wishing to know whether he shall fence his wood lot or let it remain in common, or keep the cattle out, all expenses considered. Perhaps they would die if they got in, as Judge Thaine said to the farmer fencing in Kittery common. Whether he can make trees grow in his door-yard where the soil has been stripped off; whether he had better plant horse chestnut, mountain ash, spruce, fir and pine; but then he has his doubts; and then he wishes we should solve all these doubts through the Farmer, or by a private letter. Only twenty private letters a week for a regular manual exercise!

All these men, like good honest fellows, paid their postage, which is not a little remarkable, considering the state of the currency.

11. Then comes an inquiry why butter will not come? We shall answer this in another place.

12. Next a sober inquiry about a disease, a species of murrain among the cattle in Rhode Island, which we wish much that we could answer, but our experience is small and all our books and records are 300 miles off. We advise application to the best physicians in the neighborhood. We have no opinion of Cattle Quack Doctors, though they abound.

13. Have the leaves in hard-wood land been used as manure in your vicinity, and if so, with what success? Will say some other time.

Now this is not one half. We do not complain of it. We like it. It shows the wakefulness of the public mind, which is what we want in order to make progress; for what can we do with men who are asleep? Inquiry, inquiry is what we want. It cannot be too active; too direct; too persevering and pertinacious in regard to all matters of science and practice. From inquiry will grow up, of necessity, observation. Put inquiry and observation together, and then comes truth, that most precious of all gems; that only safe guide in life; that first of all elements in the power of doing good; that first of all movements in the highway to happiness.

Now there is not a question proposed to us as above, that is not worth asking, and there is not one we will not endeavor to answer, or get some other person to answer. Let our friends give us answers as may suit their convenience, and let there be as many more inquiries sent in as you please to put. But then, gentle friends, have mercy upon us. Do not, if you find us stopping for breath, thump us upon the back too hard; we shall come to presently, and if nothing else will do we'll ask some friend to put us in the Magnetic sleep, and we shall then answer at once.

The above queries, we infer, all come from the "Lords of the Creation." We have many more from the other and better side of the house; but they, we say it in a whisper, are *strictly confidential*. To the fair friend, who asked something about personal appearance the other day, we only say, "Handsome is as handsome does."

Other Queries.

Adolescents asks some questions, which as well we can, we shall answer. We wish he had been more definite. Does he inquire to what particular science he shall turn his attention and how shall he master it; or does he desire that we should prescribe a general course of reading? In either case, however, we do not know how we could do better than to direct him to the "School Library," published by Marsh, Capen & Lyon, Boston, which embraces both particular and general subjects, and is prepared with great ability by some of the ablest writers in the country. The volumes are sold separately at all the principal bookstores in the country; and no better service could be rendered to a community of young people than to form a reading club for the purchase of all of them. Besides

these, Harpers' Library abounds with useful works, at a very low price, though they have conducted with so much trenchery in regard to some works, take for example the Life of Jay, that their books on controverted subjects are to be received with caution. In other respects, they furnish an immense amount of reading on various subjects, at a very low rate.

Female Correspondence.

We publish here a charming letter from Zelia, a kind lady, who responds to the invitation in our last. We assent to everything she says, and wish we could say it half as well. If she would only have subscribed herself Rosa, or Lilia, or Japonica, or Daphne odorata, how much more appropriate! But we welcome her to our columns under any name she may choose, thinking he must be a lucky fellow who can alter her name at his pleasure. She will find a kindred spirit in W. B. in this paper. What effect her letter will have upon this poor fellow when he comes to read it, we cannot say. He is quite plaintive she will perceive, the natural effect of his condition. We cannot quite agree with him that woman is never so lovely as when "administering to the drooping wants of the lily, or watching the expending beauties of the rose." Though fairest among all flowers, yet we think them much more lovely when "tying the old man's slipper;" or watching the expansion of far fairer flowers than those, which bloom only to perish on earth. But we are growing too sentimental. It won't do, Zelia! we must leave that to you. We had once some fire, but it is only ashes now.

M. C. COLMAN—

In the last number of your paper you say that you will be glad to hear from your female friends, on the subjects of gardening, floriculture, and other domestic matters. I am exceedingly glad that you have so promptly suggested it; matter, and I hope it will not be in vain. I hope that your generous and praiseworthy efforts to render your columns instructive and interesting to your female readers, will be by them fully appreciated, and that they, on their part, will not withhold that co-operation, which their duty as well as their interest should prompt them to bestow. The object of such journals as yours, being to promote improvement in domestic as well as rural affairs, cannot be fully attained without female aid—aid of those whose chief duties consist in domestic management.

Your extensive and intimate knowledge of the condition of our rural population, renders it unnecessary to tell you of the faultiness of female education in the country. You are aware that those of us, who have been well instructed at home, in household affairs, have not received a liberal, or seldom, an ordinary school education; and on the contrary, when much care has been taken to give us a *polite* education, that the home branches have been neglected, forgotten, and eventually despised; this remark, you know, sir, will admit of general application, though there are, of course, numerous exceptions.

Home and school instructions are by no means properly blended, and until they are, we need not expect to find a great number of female essayists on rural or domestic economy. The increased attention, however, which is now given to the improvement of agricultural science, and particularly the laudable effort which is in progress to awaken a spirit of home industry—multiply its sources—and afford it suitable encouragement, will tend in a great degree to remove this evil, as well as many others, that have crept into our domestic habits during a period of superficial wealth, and deceitful, and intoxicating prosperity.

When I took up my pen, I meant to confine myself to a few remarks on ornamental gardening and floriculture by female, the preceding remarks will, therefore, have to go for a preface.

* See N. G. Farmer, vol. 1, p. 145, and vol. 2, p. 111.

There is scarcely anything which legitimately belongs to female industry, so much neglected as that which is of all others the most agreeable, the most conducive to health and happiness, viz. the cultivation of shrubs, plants and flowers; those external ornaments of home, that throw around it such an air of comfort and contentment, that cheer, enliven, and beautify country life, that multiply and strengthen the attachment of families to their home, and that cause it to be associated in the memory, when perhaps far, far distant from it, with the most endearing recollections. If the attention of females can be generally enlisted in this cause, if they can be persuaded to venture out into the pure air, and, with their own hands, aid in the cultivation of the "loveliest of nature's gems," then we may expect a change to come over the appearance of our country homes, and such a change as cannot but give universal delight. Instead of seeing them as they now are, for the most part without a shrub, a flower, or ought that indicates an appreciation of nature's beauties, we would find a shrubbery and a flower garden a certain accompaniment of the dwelling.

Why should we devote such assiduous attention to our furniture, its brilliancy and beauty, and with an unwearied care keep all the internal ornaments of our houses in order, neatness and taste, while at the same time we never think of displaying our taste in outdoor ornaments? Is it right? is it consistent? I am sure the reader will answer no! and certainly I do. Nothing is more provoking than to hear a woman ask "what is the use of plants or flowers?" Has the Almighty created us without any other than animal feelings and appetites? What a grossness of intellect it must be that can prompt such a question! yet that same person is an ardent admirer of silk ribbons, and other similar gewgaws, and would not hesitate in sacrificing whole days and weeks of valuable time, and spending much hard earned money on fashion and frivolity!

The advantage which our health would derive from the delightful labors of the garden, is another strong argument in favor of it: three fourths of us are complaining of ill health, one of the greatest of human ills; and no one will deny but that it is caused by the delicate manner in which we are brought up. We want more exercise,—we want physical as well as mental exercise in the free open air; our health and true rational enjoyments have been sacrificed to unworthy motives. Strange illusion! That in the pursuit of mere phantoms, we should so shamefully neglect the means which a beneficent creator has kindly given us, for the gratification of the purest desires of our nature!

How is it possible that so many should seem insensible to the pleasures of the garden? What more exquisite than to leave the confined atmosphere of a dwelling, and inhale plentifully the balmy breath of morning, sweetened with the perfume of flowers, perform the necessary labor, and return to the domestic duties with a glowing cheek and a healthful appetite? How sweet to pluck the opening rose bud, or gather a nosegay which, with our own hands, we have planted and cherished! "As long as I live, flowers shall multiply in my garden, and be cherished in my bosom; and when I die, if any kind hand will place them there, flowers shall smile upon my grave." I fear I have extended my remarks too far already. I intended to allude to other matters, but will postpone them till next month, when you will hear from me again, if these humble remarks are worthy a corner of your paper. I do not write with a view of affording instruction to others, but to elicit the views of those who are competent to instruct, that I may myself learn. Were it in my power to do, say, or write anything that would promote the general good, most

happy would I be indeed. Wishing you a hearty welcome to our region, and hoping that your labors will be rewarded with the fullest success,

I am &c.
 Chelsea Hill, Feb. 15th, 1842.

ZELIA.

Cranberries.

We extract the following article from the *Maine Cultivator*, as highly deserving the attention of farmers. We have had no practical experience of this cultivation, but have known cases in which several acres of swamp or low meadow have been sown with them, which have afterwards yielded a large product. We know one instance upon the best authority, in which a farmer sold of them from his own farm to the amount of more than one thousand dollars. That they are capable of being grown with advantage upon high and sandy land, is to us a new fact; but, from the confidence with which it is stated, it certainly deserves attention. The fruit itself is healthy and, properly prepared, delicious; and large amounts are wanted as well for exportation as home use.

The cultivation of the cranberry (*Oxycoccus macrocarpus*) has not, we believe, received much attention in this region.

Most of those usually exhibited in our markets, are gathered by the country people from the bogs and swamps where they grow wild, and without any assistance whatever from the hand of man.

Like all our native fruits, however, the cranberry is susceptible of being greatly improved by cultivation. In Massachusetts many farmers cultivate from one to a dozen acres, and as the fruit brings readily a dollar per bushel in the Boston market, they find them the most lucrative crop they can raise. It is stated in the *New England Farmer*, Vol. ix, No. 18, that Mr. F. A. Haylen, of Lincoln, in that state, raised, in 1830, four hundred bushels, for which he received four hundred dollars in cash. This is profitable farming.

Kenrick, asserts Sir Joseph Banks, who had taken pains to obtain the *oxycoccus macrocarpus* from America, harvested in 1831, from a square of eighteen feet each way, three and a half Winchester bushels, being at the rate of four hundred and sixty bushels to the acre.

The soil most suitable to the culture of this plant, is a low, moist and swampy muck, but large crops have been taken from lands in every respect precisely the reverse of that in which they flourish in their natural state. Even light sandy loam, and in which there is a predominance of vitreous or siliceous matter, if manured with compost composed of clay, muck, and swamp mud, and kept uniformly and moderately humid, will produce excellent cranberries. It is even asserted by those who have had ample experience in the business of cranberry culture, that the vines, under this treatment, will not only be much more thrifty and prolific, but that the fruit will also be much larger, fairer, and of better flavor than that gathered from vines in their natural state. On most farms, however, there are numerous low places which might be advantageously devoted to this plant, and wherever such places are to be found on a farm, they should unquestionably be selected in preference to artificial or compounded soils. The method of planting, in such locations, is to dig holes in the turf, from one to two, or two and a half feet deep, and two feet over. Into these holes are placed the sods or compact turfs containing the roots which are then carefully covered with the soil and a sprinkling of beach-sand thrown over the hill. The hills should be four feet apart each way, which gives ample scope for the vines to trail or branch over. Plants cultivated in this manner, come rapidly into bearing, after which nothing more is requisite for several years, than merely to give them a slight dressing, occasionally, and to supply new plants where the old ones have decayed, or died out.

A plantation, managed in this way, is a most valuable appendage to any farm; and in this section of the country, where the fruit brings one dollar and fifty cents, and often two dollars per bushel, it would be peculiarly so. The labor of harvesting the cranberry is very simple, and very expeditiously performed by means of a rake, constructed exclusively for the purpose, and with which, in favorable seasons, a skilful hand will gather, with ease from fifty to a hundred bushels a day. W.

Titles.—A Rule.

We particularly request that all our correspondents would attach their names, places of abode, and data, to their communications. If they desire their names concealed it shall be so done.

We must ask indulgence if we withhold in all cases all titles, such as Excellency, Honorable, Reverend, or even Esquire, which in truth is now generic instead of specific; and we should be puzzled to say whom it does not designate, unless it be a woman. As things go, however, it may not belong withheld from them. Jerusalem Salmagundi, Esq., for example—how finely that appears—certainly the women cannot long resist the temptation.

In all our official reports for the last four years, we have made an absolute rule to give no title; and it has saved us much trouble. If, however, any of our correspondents desire their titles to be annexed or prefixed to their names, we promise to give all they will honestly send, whether it be F. R. S., which a fellow in England lately assumed, because he said he was Famous for eating Rich Soup, or A. S. S. which may mean Socius Societatis Agriculturæ, shall be duly displayed. In the last case however, we cannot promise that every one who does not understand Latin shall hit upon the right interpretation; any more than in the case of the Tobaccoist, who on setting up his coach and six, desired his carriage-maker to place a coat-of-arms and a motto on the door, which should reprove any who presumed to ridicule his elevation. The coach-maker accordingly put on the door the two Latin words, *Quid rides*; or why do you laugh? but which, unfortunately, by the illiterate, was read without regard to prosody, and as if it were plain English, *Quid rides*.

Gypsum.

Josiah Borwell, of South Hadley, Mass. has 1 acre of pasture ground, and applies to it annually one thousand pounds of gypsum. The same application and at the same rate, has been made 35 years in succession. On this lot he pastures annually one large yoke of oxen, one horse, two cows and some years three cows. Prior to the use of plaster, Mr. B. says it required at least six acres of this land to afford as much feed as he has obtained from one acre, by using plaster.

He has also a piece of mowing ground which contains four acres. Two crops of hay are taken from it regularly. On this ground he uses plaster of Paris freely, and applies a top dressing of manure. His annual product of hay is fully sixteen tons. P. L.

A Protector for the Defenceless.

The subjoined statement is new to us. It is made on good authority in the *Maine Cultivator*, and we hope may be well founded.

Many object to rearing hens on account of their liability to be carried off and destroyed by hawks and owls. In some situations this is a serious objection, as the hen, if suffered to run at large with her chicks, is almost certain to be lost.

But the evil may be avoided. A Guinea hen, if suffered to associate with the flock, will at all times prove efficient in protecting the latter from the hawk, who no sooner hears her voice than he takes wings and carries the war into some other quarter, where his murderous propensities for slaughter may be more easily gratified, and without the fear inspired by so valiant and powerful a foe.

The eggs of these fowls are also highly prized by some, and meet with a ready sale in our markets, being much larger than those of the common hen. W.

A meeting of the friends of Home Industry was held in Rochester on the 16th ult. The subject of governmental encouragement and protection to domestic labor, was discussed in their bearings upon labor in all its forms, agricultural as well as manufacturing, and likewise upon the commercial interests of the country. We may on some future occasion have opportunity to treat this subject more at large.

Seneca County Agricultural Society.

Through the politeness of the President of this Society, we have received a copy of its constitution and by-laws, and of the address delivered at their annual Fair on the 21st Oct. last. It forms a closely printed pamphlet of 20 pages.

The address is preceded by an interesting sketch of the history of the county, the whole of which we should be glad to transfer to our columns, if our limits admitted of it. It is from the president of the Society, G. V. SACKET, of Seneca Falls.

The country now constituting Seneca county, and in old Western New York, was in possession of the Indians until 1779, when Gen. Sullivan and Gen. Clinton entered it with a strong military force to repulse the Indians then in alliance with the British troops, and whose incursions upon the settlements of the whites had become exceedingly disastrous and troublesome. The enemy were routed and the combined forces having travelled 300 miles in a circuitous route in the wilderness, came at length upon the Lake shore. Mr. Sacket says that, until this time, none but the captives taken from our border settlements, or perchance some struggling French Jesuits, had ever set foot on our soil. Yet when the army reached the lovely Lake country, as they approached the margin of the Lake "they found in many places instead of a howling wilderness, orchards, farms, and gardens resembling civilized life." These were improvements made by the Indians. Seneca, he denominates the mother county of Western New York. In 1784 a treaty was concluded between the United States and the Six Indian Nations, and the lands east of Seneca Lake were ceded to the United States.

The change in the value of lands since that time in this part of the country, is most remarkable. Lands in this and the neighboring counties were then estimated not by the acre but by the lot, (the number of acres in a lot is not stated) and lots which then sold for \$25 per lot, are now worth \$25,000, being an increase of a thousand fold in about 50 years. Who would not have pronounced the prediction of such an advance a mere dream out of the Arabian Tales?

Mr. Sacket then speaks in an interesting manner of the first settlers, some of whom were present on this occasion; one of whom Andrew Dunlap, was the first man who put a plough into the ground between the Lakes, and now in his 83d year, acted as chairman of the committee on ploughs and ploughing on this occasion. The President pleasantly remarks, that although he is in favor of rotation of office as a general principle, yet this appointment he hopes will be continued to this patriarch as long as he can meet with them; and then he hopes to see it descend to the heir, who should occupy the old homestead. A brother of Andrew, William Dunlap, likewise a pioneer at the same time, was on the same committee.

There was no mill in the county so late as the year 1794, nor in what is now called Western New York until the end of the year 1790. Until that time the inhabitants were under the necessity of going to Rome, on the Mohawk river, or down the Susquehanna to get their flour and meal. A family of religionists under the direction of their founder, Jemima Wilkinson, came here in 1789, and built and put in operation the first mill in Western New York in the latter part of 1790. Since that time the increase of mills has kept pace with the increase of the inhabitants and the growth of wheat; and now in the villages of Seneca Falls and Waterloo there are 13 mills: most of them of

the largest class, turning 35 run of stone, and capable of flouring 10,000 bushels of wheat daily.

The county of Seneca is 33 miles long and 10 broad, containing 330 square miles. When settled at \$25 per lot, it would have been valued at \$8250. In 1840 it was estimated that 5-6th of the land had been brought into cultivation, and estimated at \$44 per acre exclusive of villages, it would now be valued at \$8,250,000. In 1789 it may have had 75 inhabitants. It now contains 24,000, equal to 75 souls to the square mile. The annual products of the county were as follows:

Wheat,	350,804 bushels at \$1.00	\$350,804
Corn,	178,671 " "	89,337
Rye,	5,520 " "	3,125
Oats,	213,826 " "	53,155
Barley,	15,819 " "	7,909
Buckwheat,	19,798 " "	9,899
Potatoes,	263,293 " "	50,848
Hay,	33,163 tons at 7.00	267,141
Beef & Pork,	20,010 lbs. at 10	206,100
Wool,	166,351 lbs. at 50	83,277
		\$1,122,105

These facts are remarkable and highly deserving of being recorded.

These historical sketches are followed by an address from A. B. Dunlap, the Recording Secretary. The subject is the "Nobility of Agriculture and the means by which it may be elevated."

The agricultural profession is to be elevated by the Archimedean lever of education, scientific and practical education. The agricultural profession is among the most important in the community. It should be among the most esteemed. The current of public opinion is now setting strongly in its favor. It has been made honorable by the application to its practical improvement of some of the brightest minds, and of men of the highest political elevation and influence.

Immense service has been rendered to the cause by various publications, especially of a periodical character. These have diffused widely a vast amount of information. Agricultural Societies have contributed most essentially to the science and the practice of an improved Husbandry. The means of advancing its progress, however, upon which he dwells with most emphasis, is the establishment of Agricultural Schools. It seems extraordinary that while the teaching of almost every other science and art is effectually and liberally provided for, this, in various respects, among the most important, should have been to so great a degree neglected. These are the main sentiments of this useful and sensible address; and we subjoin an extract.

"Wealth, influence, and talents have long been ennobled in building up the agriculture of Britain; and she will continue to take the lead of us—say and do what we please—unless science is made the basis of our agriculture. Her legislators are not unwilling like our republican statesmen to grant legislative aid to protect in every desirable way her agricultural interests. We are not launching upon the dangerous sea of experiment—we have well established landmarks to guide us in our course. Agricultural schools have been established in Ireland, in France and Germany, in despotic Prussia and Russia. The despotic reformer of down-trodden Egypt has established a school for the application of science to agriculture. But here, in this boasted land of liberty, a government emphatically resting upon the shoulders of the farmer, there is not a solitary school to foster and protect this great, this all absorbing interest—on interest upon which is based our national greatness, and upon which depends the peace and perpetuity of our free institutions. We require the physician to have a knowledge of his profession, before we entrust to him our lives and limbs. The lawyer

must understand the laws, before we allow him to take charge of our property; and the divine who has not stored his mind with the truths of both natural and revealed religion, is a blind leader of the blind. What then shall we think of the doctrine that the farmer has no need of preparation in order to fit him for his elevated calling? We have our law schools, our medical schools, and our theological schools; and now we ask the important—the weighty question—why shall we not have our agricultural schools?

We now close the subject, trusting that an intelligent and enterprising community will answer the question, as their important interests, individual, social, and political, require—as the spirit of the age and the honor and independence of the nation demand. We have glanced at a few of the means by which the character and standing of the American farmer can be elevated, and his profession raised to that point where nothing shall be above it but "God and the Laws"—means which will bring back the golden age of husbandry, when

"The sacred plough employed
The kings and awful fathers of mankind;
And some with whom compared your insect tribes
Are but the beings of a summer's day,
Have held the scale of empire, ruld the storm
Of mighty war; then with unwearied hand
Disdaining little delicacies seiz'd
The plough and greatly independent liv'd."

The address is followed with a list of premiums and the names of the successful competitors. Few things will more contribute to the success and popularity of the Society, than the publication annually of its transactions, annexing the address, the reports of committees, the names of the winners of the prizes, their accounts of their cultivation and management in all their details, a list of members, a list of officers, a list of premiums, and generally some valuable agricultural communication or information which may interest the farmers. This being sent to every member, will put him in mind of paying his subscription, will lead him to induce his neighbors to become members, and will create an interest in the Society most conducive to its increase, its successful management, and its beneficial fruits.

The following are the Officers for the ensuing year:

President,

G. V. SACKET, Esq., Seneca Falls.

Vice Presidents,

NATHAN W. FOLWELL, Lodi,

TRUMAN BOARMAN, Covert,

WM. R. SCHUYLER, Ovid,

JOHN D. COE, Romulus,

JOHN V. MANNING, Varick,

JOHN JOHNSTON, Fayette,

JOEL W. BACON, Waterloo.

MATTHEW W. WEST, Junius,

JASON SMITH, Tyte,

JACOB KISHLER, Seneca Falls.

ABRAHAM B. DUNLAP, Ovid, Rec. Secretary.

SAMUEL WILLIAMS, Waterloo, Cor. Sec'y.

JAMES STEVENSON, JR., Waterloo, Treasurer.

Sleeper's Address.

An ADDRESS delivered before the Agricultural Society of Westborough and vicinity, Mass., Oct. 1841.

By JOHN S. SLEEPER, ESQ.

This address abounds with sensible remarks and useful suggestions, and advice to the agricultural classes, given in a perspicuous style, which is not a common characteristic, and in a lively and playful manner as to attract attention; which is as it should be.

The Society before which this address was delivered, consists of farmers of Westborough, one among the best farming towns in Massachusetts, and some of the neighboring towns, who meet occasionally and frequently for mutual inquiry and discussion in relation to the great art by which they subsist; for the intercommunication of their own actual experiences; and the im-

erting of such information as any may have acquired, they hold likewise in the town, an annual cattle show, in which they display their best stock, and exhibit some of their products, which are examined and reported on by committees appointed for that purpose. This is a specimen of many societies, founded on the same plan, in different parts of the state. They are eminently beneficial; they stimulate inquiry; they arouse a whole-menculation; they lead to experiments; and are instrumental in diffusing a good deal of practical information.

We should be glad to give this address entire, but our limits forbid it; and we must confine ourselves to some brief quotations.

"Out of thirteen millions of the population of Great Britain, engaged in various pursuits, nine millions are employed in agriculture. And the soil of Great Britain is by no means naturally fertile, but requires the continued application of art and labor to keep it in a highly productive state. Yes, in Great Britain, land represents more than seven times the value of manufacturing capital, four fifths of which capital is employed in furnishing the requisite supplies to agriculturists. And the average net profit arising from the immense landed capital is estimated at seven per cent. and a half per cent. It is therefore generally limited in Great Britain, that agriculture is the basis of British prosperity, and the chief pillar of the government; and the broader and firmer the foundation, the more profitable and durable will be its concomitant lies, manufactures and commerce.

This fact is well illustrated by an allegorical sign in a country inn, called the "Five Ails." It represents five human figures, beneath each of which is a motto. The first figure is a king with his regalia; his motto, "I govern all." The second, a bishop in his pontificals; his motto, "I pray for all." The third, a soldier with his gown; his motto, "I plead for all." The fourth, a soldier in his regiments; his motto, "I fight for all." And the fifth, a farmer, in appropriate costume, with his scythe and rake; motto, "I pay for all."

In the United States, the actual produce of our soil, unless in seasons of great scarcity, after supplying the demand for home consumption, furnishes three fourths of our exports to foreign countries. And our agricultural riches thus give an impulse to commerce and manufactures, and enable us to import comforts and luxuries from abroad, by which a revenue is derived for the support of the government. According to the Report of the former Secretary of the Treasury, giving the value and quantity of the agricultural productions in the year 1839, it appears that in that year the article of greatest value produced was *hay*. The number of tons computed to have been raised, being 9,830,415, which at 80 cts. a hundred weight, the average price in the New York market, amounted to the enormous sum of \$157,286,840! The article next in value was *Indian corn*, viz., 98,161,445 bushels, which, at fifty cents a bushel, amounted to \$154,080,223. After it comes *cotton*, about one billion three millions of pounds, which at even cents, gives \$114,006,577. Then we have *potatoes*, amounting to 73,983,449 bushels, at one dollar a bushel; *potatoes*, one hundred and two millions of bushels; which at 42 cts., gives 42,682,000 dollars. *Products of the dairy*, equal to 31,159,000 dollars. *Oats*, at 33 cts. a bushel, amounting to 33 millions of dollars; then *sugar*, 19 millions of dollars, and tobacco at 10 cts. a pound, amounting to \$14,300,000.

In these returns the product of North Carolina, Kentucky Florida and Wisconsin, are not included; and it is believed that the production, as published, is fully ten per cent. below the actual product. Enough however is known to satisfy the world that we possess immense wealth. For the annual value of agricultural productions alone, as officially given in this Report, is nearly seven hundred millions of dollars! This was the product in 1839; that of 1840 was certainly ten per cent. greater; and there is good reason to believe that the product of 1841 is larger still.

On reflecting on these facts, every patriot must wish that agriculture may experience the fostering care of government; that our legislatures may do more for the farmer, instead of undoing what has already been done; that agricultural societies may multiply in our land; and where facts may be gathered and knowledge diffused; that well-conducted agricultural publications may be well sustained by the agricultural community, and circulate extensively on every side; that agriculture may be made a branch of study in our

schools; and that a professorship may be established in our colleges."

"In concluding this address, I would say to all farmers, cherish your occupation, and maintain its respectability on all occasions, and at all hazards. Be faithful to yourselves, and you will find no one to dispute with you the antiquity, the utility, or the elevated character of your occupation. Be industrious; for industry is the landmark of health, and the key to unlock golden treasures. However great the beneficence of nature, she gives nothing gratuitously to man.

Study and practice economy, for it should ever be remembered, that although labor creates wealth, economy accumulates it. By economy I do not mean a sordid, grasping, avaricious spirit; for true economy is as far removed from that on the one hand, as from heedless extravagance on the other. Study the comfort and happiness of your family, but avoid luxury as an evil of magnitude. Remember that the introduction of luxury into kingdoms, states, or empires, has precipitated them from the summit of power, and from the most flourishing pitch of glory and renown.

Be temperate in your habits. On this much depends. The pure water which gushes from the hill-side, and meanders through the fields and meadows, is the drink which the bounteous Giver of all good designed for man. Intemperance is a rock on which many a gallant bark has been wrecked. Industry and economy cannot be practiced except in connection with temperance, as the helpless fate of many otherwise able and worthy husbandmen have proved. It should ever be borne in mind, that in this country, industry, frugality, and temperance will always conduct a man triumphantly through the paths of life.

Cultivate your minds. This may be done by reading, by study, or by conversation. A good farmer, who manages his concerns as they should be managed, will always find time to cultivate his intellectual faculties, as well as to exercise his physical powers; otherwise, he were indeed to be pitied. There are times when the mind should be exercised as well as the body; when information on various subjects of general interest should be obtained, of a character more solid and enduring than can be found in the newspapers of the day. Books and periodicals may be had in these "go ahead" times, on almost every subject, in forms exceedingly cheap, and well-selected social libraries should be established in every town or village in New England.

See that your children are well educated. Let your sons be instructed in the various branches of useful learning, that they may become active and worthy members of an enlightened community. Indulge on their minds elevated sentiments and liberal principles. Teach them that they should not live for themselves only; that in this republic, every man is a pillar of the state, and exerts an influence in society, and has indispensable duties to perform, to his family, his country, and his God.

Let not the education of your daughters be neglected, for on the character of our women depends the future fate of our country. Teach them early to look upon the labors and the profession of a husbandman, with smiles and sympathy, for we all well know, that in civilized communities, where the influence of the gentleman is all powerful, as it should be, no enterprise can succeed, or become popular, without being cheered by the smiles and sympathy of woman, the "flower of the human species." Educate your daughters so that they will make good farmers' wives, and, if thus educated, they will reflect honor on any station, however exalted, and be worthy to become the mothers of freemen."

Floriculture.

Bring blossoms of every hue and name,

And buds for opening youth,

Garlands for honor and wreaths for fame,

And fadeless flowers for the purest flame

Of the heart's enduring truth.

Flowers for the mourner, flowers for the bride,

Or garnish the hall of death,

And to strew the biers of them who died

In youth and age and manhood's pride,

For such and for all a wreath. Locke.

In all ages and in every clime, the love of flowers has been cherished and cultivated with increasing attention and admiration. They have received the fondest titles that sympathy or affection could offer, and in their opening petals and fading beau-

ties, they invite to the most pleasing reminiscences and reflecting reflections that are associated with life. In the one, we behold the morning of our own existence beautifully exhibited with freshness and dews of youth upon us; while the other, invites the reflection that "all flesh is grass, like the grass it withereth, and like the flower it fades and its goodness passes away." Thus every age finds in them some emblem of its own fleeting being, and every circumstance of life may hail them as counterparts.

In ancient times they were employed to deck the feast, and strew upon the bier and grave where affection called the admiring crowd for convivial festival, and weeping sorrow laid its loved one to repose. They were spread in paths of triumphant warriors as the emblems of victory and honor; and in gay wreaths adorned the brow beneath which gay and happy hearts beat in holy response at love's pure rituals.

They bloom alike in the limited territory of the cottager, and in the proud and extended parterres of the wealthy and the gay.

A love of flowers has ever been regarded as an index of moral excellence and intellectual refinement. Who that beholds their unostentatious elegance, their gay simplicity, and unassuming beauty ever turn away from them without being impressed with the emptiness of artificial pomp and splendor? Who that witnesses their evanescence, will not read effectually the lesson of universal frailty and decay? For childhood and youth the cultivation of flowers presents an imposing employment and an interesting and instructing amusement. In the period of existence, when care does not present its corroding anxieties; when the spirits are free and buoyant, and the world smiles fresh and gaily on every hand, when expectation is buoyant in looking through life's vista as upon a bed of flowers; when home and dear associations are binding the soul in a thousand ties as indissoluble as existence; when every scene and every object is impressing the mind with images which are to dwell like bright spots upon the memory, when manhood comes with its sober reign and age with its furrowed brow and silvery hairs,—in the morning of being when every action does its full share towards laying the foundation of thought, feeling and principle for life, what employment for leisure hours can be more appropriate, than aiding the floral world in its grand designs of beautifying the earth, and what teachings of wisdom can be more powerfully inculcated than those taught by the simplicity and purity of nature?

To the female sex, in every period of life, it offers considerations of great and abiding import. From them they may derive rich lessons to aid them in rearing the temple of the mind in those who are to succeed them, a sphere peculiarly their own, and to close with a response to the interrogatory of another, there is no object in nature more beautiful than a young and lovely woman seen in a parterre of flowers, herself the fairest, adorned with innocence and virtue, administering to the drooping wants of the lily, or watching the expanding beauties of the rose.

W. B.

February, 1842.

Cleaning Glass.

The French mode of cleaning fine glass utensils, &c., gives them great brilliancy. It is done by finely powdered indigo, and dipping into it a moistened linen rag, with which the glass must be smeared, and wiped off with a perfectly dry cloth.

As a substitute for this, fine sifted ashes, applied by a rag dipped in spirits, will also answer very well; but Spanish white is apt to roughen and injure the glass.

Improved Stock.

We invite the particular attention of those interested, to the sale of Mr. Weddle's Improved Stock, advertised in this number. It presents an opportunity of obtaining some of the best animals of the kind for breeding, to be found in this country.

Agents for the New Genesee Farmer.

In addition to the numerous Postmasters and other friends of Agriculture who have kindly aided the circulation of this paper, the following persons will receive Subscriptions in their different towns and cities.

Newburyport, Mass. J. Colman.
Worcester " Clarendon Harris,
Lowell, " D. Bixby,
Salem, " John M. Ives; Francis Putnam,
Greenfield, " James Deane,
Lynn, " Charles Coudage,

CLOVER AND TIMOTHY SEED.

OF the best quality, free from four seeds. For sale at the Seed Store. M. B. BATHAM.

LARD LAMPS.

THE subscribers have just received a large lot of the above mentioned Lamps, and will invite the attention of farmers, mechanics, and others who wish an article from which the cheapest light may be obtained from the use of Lard. They burn well, and in a great measure are doing away the use of candles, and are not supposed to be dangerous, and are worth the trade of every domestic economy. To be had at No. 3, Exchange-st., at wholesale or retail.

BREWER WATTS, & Co.

Rochester, March 1st, 1842.

FARMS.

FOR SALE, on a long lease, a farm of 50 acres—10 acres improved—with a good house and barn upon it, in the town of Ridgeway, Orleans Co. Also a farm of 110 acres—70 acres improved—with two houses and a barn upon it, in North Clarence, Erie county. Apply to Wm. R. Montgomery, at his office, or to H. MONTGOMERY, No. 4, Spring-st.

Fruit and Ornamental Trees, Shrubs, Green House Plants, &c. &c.

THE subscribers are prepared to execute all orders for Fruit and Ornamental Trees, Flowering Shrubs, Green House Plants, Bulbous Flower Roots, Double Dahlias, and all other articles in the Nursery line, on the most moderate terms. Persons who are about establishing new Nurseries, or wish to act as agents for the sale of any of the above articles, will be very liberally dealt with, and are requested to communicate their intentions to us immediately. Where several persons in the same neighborhood, are desirous of procuring trees, they will do well to unite their orders, and let the subscribers be forwarded in direct proportion. All orders must be accompanied with cash or a satisfactory reference in Rochester or vicinity. Price Catalogues will be sent gratis to applicants. For want of space, we cannot give a full list of the articles we have on hand. Address (Post Box) LEVANGER & BARRY, Mt. Hope Botanic Garden and Nursery, Rochester, N. Y.

Valuable Works on Horticulture and Agriculture.

Just received by Rail Road, from Otis Brothers & Co., Publishers, Boston.

THE NEW AMERICAN ORCHARDIST; or an account of the most valuable varieties of FRUIT, of all climates, adapted to cultivation in the United States; with their history, modes of culture, management, uses, &c. With an appendix on vegetable, ornamental trees, shrubs and flowers, the agricultural resources of America, and on Silk, &c. By Wm. Kenrick. Third edition, enlarged. THE NEW AMERICAN GARDENER; containing practical directions on the culture of fruits and vegetables, including Landscape and Ornamental Gardening, Grapes, Vines, Strawberries, &c. &c. By Thomas J. Fessenden, editor of the New England Farmer, and author of various other works. THE COMPLETE FARMER, and Rural Economist; containing a compendious epitome of the most important branches of Agriculture and Rural Economy, by Thomas G. Fessenden. Fifth edition, revised, improved and enlarged. The above three books uniformly bound, in beautiful style—per \$1, each—are for sale at the Rochester Seed Store and its Agents. M. B. BATHAM. March 1st.

GENESEE NURSERY.

THE subscriber has constantly for sale at his Nursery on Main street, one mile East of the Bridge in Rochester, a choice selection of Apple Trees of large size, warranted of the kinds represented, embracing about 40 of the best varieties of fruit, such as the Winter use, price \$3.50 per tree; a liberal discount to those who may purchase in large quantities for retailing; or from a distance containing remittances for good early references will receive prompt attention, and the trees will be shipped or delivered as directed. Also a few Peach and Locust Trees for sale.

ELECTUS BOARDMAN.

The above Establishment has been carried on in this town over 20 years.

New Arrival from England.

JUST received from London, viz. Boston, a large assortment of seeds of the growth of 1841, embracing a full supply of all kinds of Cabbage, Cauliflower, Broccoli, Irish, Turnip, Ground, Purple top, Purple top, Purple top, Mangold Wurtzel, white Dutch Clover, a choice lot of Flower seeds, and a multitude of other things—See CATALOGUES.

M. B. BATHAM.

Hatch's Sawing Machine, in Ohio.

Answer to several inquiries on the subject, Mr. Hatch announces that he is willing to dispose of the right of his machine for the whole state of Ohio, on very reasonable terms. He has one of the machines, which he has at the farm of J. W. Smith, Esq., at Maumee City; and one will be sent to Cleveland, on the opening of navigation.

LEBIEG'S AGRICULTURAL CHEMISTRY—For sale at the Seed Store, price \$1.50.

A Nurseryman Wanted, in Ohio. The proprietor of a well established and favorably situated Nursery Garden at Columbus, Ohio, wishes to engage a man of some experience in the business, to take the management of the establishment, either as a partner, or for salary. Address, if by letter post-paid.

J. A. LAZELL.

Columbus, Ohio, Feb. 1, 1842.

GREAT SALE OF BLOODED STOCK. I propose to sell by Public Auction, on Tuesday 29th March, at my farm in Greece, adjoining the Erie Canal, six miles west of Rochester, all my blooded and grade stock, including my choice of Cattle, Horses, Sheep, and Swine. Sheep and Hogs, the particulars of which, with pedigrees of the same, will be given at a future day.

Rochester, Jan. 25, 1842. THO'S WEDDLE.

FRUIT TREES.

THE subscriber has just prepared to furnish in large or small quantities, the finest varieties of Fruit Trees. Flowering Shrubs, Herbaceous plants, Bulbous Flower roots, Double Dahlias, Green house plants, &c. Also, GARDEN SEEDS, raised by the proprietor at the Rochester Seed Garden, and put up in boxes or packages to order, all of which are warranted genuine as represented, and of superior quality.

Orders for the Spring, will be promptly attended to on very liberal terms, when accompanied with cash or satisfactory references.

Selections will be made by the proprietor, when requested.

C. F. CLOSSMAN.

Rochester, Feb. 1st, 1842.

NEW CUSTOM MILL.—The subscriber having taken the White Mill on Water Street, East side of the river for the purpose of running it as a custom mill, he gives notice that he is now prepared to do work in as short a time and as well as any Mill in Western New York, and with his facilities and a close application to business, he is in hopes of procuring and obtaining a share of public patronage.

WANTED immediately, 5000 bushels Wheat; also Barley, Beans, Oats, Peas, Grass Seed, Flax, Flax Seed, Bristles, Bees Wax and dried Fruit for which the highest market price will be paid.

N. B. Flour will be at all times manufactured on the most reasonable terms for merchants or others who wish grain for seed.

Rochester, January 1, 1841. 3m W. C. FOSTER.

Rochester Seed Store and Agricultural Repository.

THE proprietor of this establishment, would now inform his friends, that he has just received the charge of the New Genesee Farmer, [to alter hands,] he will hereafter devote his whole attention to the business of the Store, and to the sale of the various articles in the establishment to his customers. A full supply of nearly all kinds of SEEDS are now on hand for the coming season; part of them raised in this vicinity the past season, by C. F. CLOSSMAN and his brother, and the rest obtained from the most respectable foreign sources. Knowing that success in this business must depend on merit, great pains will be taken to have all seeds just what they should be of the right kind and the best quality.

OF AGRICULTURAL IMPLEMENTS, GARDEN TOOLS, BOOKS, &c. There is a good supply on hand, but many more will be obtained in the spring, and in the autumn, to enlarge the establishment so as to allow more room for this class of articles.

Merchants will be supplied with seeds for retailing, at very low prices. The usual number of Agents will receive assortments on commission as heretofore, during the winter.

See CATALOGUES gratis.

Rochester, Feb. 1st, 1842.

M. B. BATHAM.

A FINE FARM FOR SALE.—Of fifty acres of land, situated only about a half and a half mile from the centre of the flourishing city of Rochester, N. Y. on the south-east road leading from Monroe street east, and half a mile from the city, and containing a large barn, and fences—a fine orchard, good wood and water, &c. For further particulars, enquire on the premises, or address C. W. J. Rochester Post Office, N. Y. Post paid. Rochester, Dec. 20th, 1841.

THE NEW GENESEE FARMER,

AND GARDENER'S JOURNAL.

VOLUME THREE—FOR 1842.

THE Cheapest Agricultural Paper in the Union—10 to 16 Large Pages Monthly, (with engraving only 50 Cents per year.)

HENRY COLMAN, EDITOR.

(Late Agricultural Correspondent of the State Massachusetts, and Editor of the New Eng. Farmer.) Grateful for the extensive patronage which the New Genesee Farmer has received during the past year, the proprietor now has the satisfaction of announcing that the paper is such an encouragement for the year a constant and highly gratifying to the readers of the paper, and secured at a still more extensive circulation.

Post Masters and their Assistants, are authorized and specially solicited to act as Agents and remit subscribers for the Farmer. The low price at which it is published will allow of much pecuniary compensation to Agents, & it is believed they will find a reward in the benefits which result from the circulation of such periodicals in their neighborhoods.

Persons ordering papers are requested to strictly state the Towns, and be careful to write plainly the names of all subscribers, their Post Office, County, State; and in cases of sending the money with the order, so that the propriety of paying for the paper may be beyond all doubt.

TERMS.—If current money is sent (such as New York or New England bills) commission will be allowed as follows:

Seven copies, for.....\$3.00 Payment always to be made in advance.

Twelve do. for.....5.00

Twenty-five do. for.....10.00

No commission will be allowed on an account money is sent.

The Monroe County Agricultural Society

Held a Special Meeting on Thursday, 17th ult., for the purpose of fixing a list of premiums and arranging the time and place of the next Cattle Show. The business not being completed, the meeting stands adjourned to the 2d Tuesday in April, being the 13th day of April, at 10 o'clock, A. M., at the Arcade in Rochester.

Much interesting matter will come before the meeting and a general attendance is requested.

Gardening.

For remarks on the time for performing the different operations in the garden, we must refer our readers to the two former volumes of the Farmer. More particular directions for cultivating various garden crops, will be given in successive numbers during the present spring and summer.

Rolling Wheat in the Spring.

Mr. Colman—

It is evident that much of the wheat through the country, especially on moist mucky lands, is injured by the frequent freezing and thawing during the past winter. Unless something can be done to remedy the evil, to some extent, we have to fear quite a failure in the coming crop.

Farmers may say that they have done all that they can do to secure a crop; but there is one thing which, if done in season, may effect a great saving. Let every farmer who has not one, provide himself with a good roller, and as soon as the season of freezing and thawing is over, roll his wheat fields thoroughly, and I have no doubt that it would save thousands of bushels of wheat in Western New York, the present season. Farmers! try it, leaving a part of a field unrolled, and give to the community the result of your experience at some future time.

M. N.

Genesee Co., March, 1842.

Editorial Remarks.—Rolling and Harrowing Wheat.

The above advice is seasonable, and, we have no doubt, judicious. We should recommend something more than rolling; and that is, harrowing before rolling. As soon as the land is well dried, give your wheat fields a good harrowing, by passing over them with a horse harrow or one not too heavy; then roll them. In a fortnight or three weeks more go over them again with a harrow and a roller. Do not be afraid of destroying your wheat. Unless your harrowing is too heavy you will not displace or pull up many plants; and the advantages which those which remain will derive from the operation, will be a full compensation for any loss in this way. We have fully tested this matter more than once, having harrowed

our wheat crops twice in a season, and after the plant was eight or ten inches in height; and with decided advantage, having left in such cases parts of the field untouched with a view to determine the expediency or in expediency of the operation. The result has been highly beneficial. The effect of it is, by stirring the ground, to bring the air to the roots of the plant, and to loosen the soil so that they may extend themselves freely. This induces a vigorous vegetation, and causes the plant to tiller abundantly and throw out numerous shoots from the crown. We advise to harrowing only in one direction. The rolling will serve to break the clods and to fix the plants, which are thrown up, in the ground. In England, wheat is frequently sown in drills with a machine adapted to the purpose; and afterwards cultivated by a cultivator, contrived to pass through and loosen the soil in the rows, as we plough and cultivate between the rows of our Indian corn. This is said always to be beneficial to the crop, though with our imperfect means such refined tillage can hardly be looked for, and with prices of labor among us, might not be compensated.

We have yet to learn the value of constant tillage to the growing plant; and believe it would be found of the highest importance to our Indian corn to plough and cultivate it much more than we do. These suggestions coincide with the true philosophy of vegetation as far as it is understood, as such tillage causes a discharge of ammonia from the decaying vegetable matter in the soil, and quickens the receptive powers of the roots and leaves of the plant to take it in.

Value of Root Crops.—Mr. Sheffer's Practice.

Mr. Editor—

In order to show that all the farmers of Wheatland do not agree with Mr. Garbutt in the opinion that root crops cannot be raised *extensively* to advantage by farmers in this country, it is only necessary to refer to the practice and opinions of Mr. Geo. Sheffer, some accounts of which have repeatedly appeared in the Farmer.

In a conversation held with him a few days since, he stated that the quantities raised by him the past season were, as nearly as he could estimate, as follows:—

8 acres of potatoes, yielding	2,000 bush.
3 " of Sugar Beet and Mangel Wurtzel,	2,500 "
2 " of Carrots,	1,100 "
3 " of Ruta Baga, (injured by drought)	900 "
Making in all,	6,500 "

The Beets, Carrots and Turnips, he finds by actual calculation, cost him on an average less than 6 cents per bushel, including all expenses; and he considers them worth about double that price for feeding stock; the beets he feeds to cows, oxen, fattening cattle, &c.; the carrots for horses and hogs, and the ruta bagas for sheep.

His farm stock the past season consisted of—

60 head of horned cattle,
12 Horses,
190 Sheep,
128 Hogs, (56 fatted).

If Mr. Sheffer were as expert in the use of the pen as he is with the plough and hoe, he could easily furnish statements of the results of his experiments that would plainly show the advantages of root cultivation.

M. B. B.

Remedy for Choked Cattle.

Mr. Editor—

In last month's Cultivator I noticed a simple instrument recommended for unchoking cattle; but simple as it is, I consider it would be very dangerous in unskilful hands. Having some years ago lost two valuable cows by quite as simple a thing being pushed down their throats to unchoke them, I would by no means recommend the use of it. In discharging it, however, I will substitute a remedy quite as simple and efficacious, and much safer. Take a round stick about 12 inches long and the circumference of a common rolling pin, used for rolling out paste, cut a notch round each end of the stick and tie some twine in the notches; put the stick into the creature's mouth and fasten the twine round each horn to keep the stick in its place; when this is done, turn the animal into a yard, and have a little patience, and it will unchoke. I have tried this frequently, and never knew it to fail. I am not philosopher enough to explain the principle of this operation, but I imagine that the external air or the breath of the animal, or both together, act upon the substance and corrode it, so as to allow the creature to swallow it. Be that as it may, you may rely on the practical result. Yours truly,

January 20, 1842.

B. M.

AGRICULTURAL INTELLIGENCE.

HEREFORD AND IMPROVED DURHAM CATTLE.—It is stated that at the great Agricultural Cattle show last autumn at Smithfield, the largest ever holden in England, out of eleven premiums open to general competition, the Hereford oxen took

Three First Premiums,
Two Second Premiums,
One third Premium.

The Durham oxen took

One First Premium,
Two Second Premiums,
Two Third Premiums.

Earl Spencer, the great advocate and breeder of Durham Short Horns, admitted the defeat; but expressed his determination to beat the Herefords next year. We shall see.

FARM SCHOOL.—Benj. Bussey of Boston, lately deceased, with most distinguished liberality, has left, at the decease of some heirs, half of his estate, valued at more than 300,000 dollars, for the establishment of an agricultural school on his beautiful and highly cultivated farm in Roxbury, six miles from Boston. It would be difficult to find a more eligible location for this object; and the farm is one of the most improved in Massachusetts. No expense has been spared in its cultivation; and the stone walls upon it in particular, for their firmness and beauty, considering their extent, are not equalled in the country.

CORRESPONDENCE.

Nothing could be more gratifying to us than the reception of the subjoined letter and the annexed communication under the head of 'SCIENTIFIC AGRICULTURE.' It is the bright face of an old friend in a strange land. Who does not know the sunshine, which such an incident at once pours into the soul. We welcome him to our columns in fulfilment of his promise; obligations which so few men are apt to remember at a distance of four hundred miles. We beg to assure our readers that communications from this source will always be entitled to the highest respect and confidence. Our plainest matter of fact men will not, we hope, be deterred from their pursuit. Facts are valuable; and not less important must it be in many cases to know the reasons of those facts. To search into the causes of things, and if possible, to unravel the mysteries of nature, is one of the highest exercises of the human understanding. Our line is limited, but let us not think that we have reached the end of it, while we have the power of trying to go farther. Truth does not always float upon the surface of things. The pearl-divers of the Indies fearlessly plunge even into the troubled waters, and the most precious shells are often brought up from the lowest depths.

MY DEAR SIR—

I beg to hand you the inclosed for your perusal, and if you think fit, for publication in the New Genesee Farmer; if you approve and publish it, I will follow it up, if not I shall not be the least disappointed. The reason I write is that although Liebig's work is pretty generally distributed, yet, in order to get our farmers to understand something of the subject, it is necessary to keep the subject continually before them; and I also think that the more the subject of agriculture, or farming let us call it if you please, is elevated by being yoked to science, the more the practitioner will feel his mind and his pursuit elevated, and the more ability and dependence on his own judgment and powers will result. In other words, the more mind is used in the pursuit, the more will it be raised in general estimation, the more inviting will it become to the general population of the United States, who, if it be a fault, certainly possess that of too often abandoning the mechanical for the mental industry, to the great depression of agricultural industry, and the too great elevation of speculative or inventive conceits. Yours, J. E. T.

Boston, February 15, 1812.

On Scientific Agriculture,--Letter 1st.

I beg to congratulate you on your assumption of the editorial chair of a publication whose object is to support and promote the most important and prominent interest of this great country, AGRICULTURE; and while I congratulate you, I feel that I may with equal justice, congratulate the agricultural community on the assumption of this important office by one who, sensibly alive to all the mechanical and practical parts of this great science, yet does not lose sight of that mental part of it which is beginning to be developed by the writings and studies of men of the most cultivated intellect of the present day.

It will be readily imagined that I refer chiefly to those scientific principles of agriculture, the discovery of some of which, and the stability imparted to others which had been already broached, will forever reflect honor on the name of Liebig.

These principles are not only receiving daily confirmation by the labors of science in every civilized country, but are also being considerably extended; and as utility is the foundation of all the recent researches on this subject, it is almost certain that the results of many of them must be of incalculable advantage to the farmer.

In an admirable discourse lately delivered before the School of Medicine at Paris, Mr. Dumas has discussed with singular ability, the science of the vegetable

kingdom: with the assistance of this and many of the principles developed by Liebig, I propose to address a few letters to the farmers of the United States, chiefly with the view of enabling them to understand not only these new views, but to follow and judge for themselves of the application of many future principles which are certain to be hereafter developed, perhaps in rapid succession, from the immense labor now bestowed on the subject.

It is a task, however, which I approach with much doubt, not, perhaps, so much from want of understanding as from a want of power to explain with sufficient simplicity and clearness, a scientific object to unscientific minds. Should I succeed in enlightening a few, my pleasure will be great; should I fail, it is only in an object where thousands have failed before me.

The subject proposed is a brief account of vegetation, its wants, and the means of supplying those wants.

There are a few names in science which require a simple and popular explanation, as these names represent substances of which vegetables are composed and on which they are nourished. The first is CARBON—a solid substance of which the solid parts of vegetables are chiefly composed. When this carbon is combined with a gas called oxygen, it also takes the form of a gas, which is called Carbonic acid gas. All the carbon of which a plant is composed is taken up by the plant in the form of this Carbonic acid gas; the plant by its action, separates the oxygen from it, and retains the solid carbon; these additions of carbon constitute the growth of the plant,—hence the necessity of a sufficient supply of Carbonic acid gas, which is not only dispersed through the atmosphere in great plenty by the respiration of man and animals, but is also formed, according to Liebig, during the decomposition of humus or guano.

The next is AZOTE or Nitrogen—a gas forming part of a substance called ammonia, or rather of a salt of ammonium, as well as also, of salts called nitrates; this is chiefly used by vegetables in the very early formation of all their solid parts before the complete deposition of carbon from the carbonic acid.

Then HYDROGEN—a gas which, combined with oxygen, forms water; from the decomposition of water the vegetable obtains its hydrogen gas, which is used by it in the composition of the fat and volatile oils and resins which abound in many plants and seeds, and in the bright waxy varnish with which many leaves are covered.

Oxygen, also a gas—this and hydrogen gas mixed form water, this and carbon mixed form carbonic acid gas. Oxygen gas is absolutely necessary for the respiration of man and animals; they consume it hourly in large quantities—plants supply it to the air by separating it from carbonic acid when they want the carbon, and from water when they want the hydrogen of water. Besides these substances, the ashes of plants when burned, contain potash, soda, lime, silice, &c., these are taken up by the roots as watery solutions, and after due evaporation of the water through the pores of the leaves, are left in the plants.

Some plants require soda, others potash, others lime, and others silice; some require one, two or three of these substances in order to flourish luxuriantly.

We have then, to deal with a vegetable organized out of Carbon, Azote, Hydrogen, Oxygen, and the watery solutions of soda, lime, potash and silice, and from these few substances combined in different proportions among themselves, all the various pices, gums, stens, leaves, seeds, &c., of plants are formed.

It will be, therefore, of use to consider these substances separately, and to explain the mode of operation of each in the vegetable system, beginning with

CARBON.—It has been stated that the carbon required by plants, is obtained entirely by the decomposition of carbonic acid, effected by the powers of the

plant itself—that this carbonic acid is derived chiefly from the atmosphere is considered to be proved by many experiments, particularly by one of Boussingault, who sowed pease in pure sand and watered them with distilled water; in neither of these could there exist carbonic acid, yet they attained perfect development both of flower and fruit. He also inclosed vine leaves in a globe of glass, and then directed a stream of air upon them, from which they abstracted all the carbonic acid. In both these cases the carbon used by the vegetable was taken from the atmosphere. It is, besides, considered impossible that the earth surrounding a large oak tree, for example, should ever have contained a ten thousandth part of the carbon contained in the tree, so that the chief part of it must have been derived from the atmosphere.

When this carbonic acid is exposed to light in the leaves, it parts with its oxygen, the carbon remains behind in the solid shape of wood, vegetable fibre, cells, and various other forms, requiring for this purpose simple admixture with water. If twelve parts, called *molecules*, of carbonic acid are decomposed and lose their oxygen, they are combined with ten parts or *molecules* of water, and of this mixture is formed cellular and woody tissue, starch, and dextrine.

These substances are then of the same constituents, only they possess a different arrangement of their molecules.

Woody fibre, as well known, is insoluble;

Starch coagulates by heat;

Dextrine is soluble in water;

And yet these substances are produced by the same elements, combined in the same proportions, only differing in the arrangement of their molecules. The use of woody fibre is well known; starch is accumulated around buds and the embryos in seeds for their early nourishment; and dextrine is a watery solution conveyed by the sap to all parts of plants for its use.

How admirable the simplicity of nature, which out of the same substance can form three different ones, which can be converted into each other with the slightest expense of force, in changing the arrangement of their molecules.

It is also by means of carbon and water that the sugary or saccharine juices of plants are formed; twelve molecules of carbon and eleven of water, constitute the sugar of the cane which crystallises; twelve molecules of carbon and fifteen of water, constitute the sugar of the grape which will not crystallise.

These woody, amylaceous (starch) gummy, (dextrine) and saccharine (sugar) matters which carbon, in its nascent state, can produce by uniting with water, play so important a part in the life of plants that, when rightly considered, it is not difficult to estimate the value of truly understanding the decomposition by plants of carbonic acid, which, as is justly observed, is furnished in various ways by nature in such abundance as not to require the care of the cultivator.

Man, and all animals, consume a large quantity of carbon by slow combustion. The products of the combustion of carbon, whether quick, as when charcoal or anthracite coal, which are only other forms of carbon, are burnt, or slow as when consumed by man and animals, are heat and carbonic acid: the heat produced by the combustion of charcoal or coal, is well known; that produced by the combustion of carbon in the animal frame, is the heat of the body. Man and animals respire and breathe out, therefore, constantly a large quantity of carbonic acid, being the product of their slow combustion of carbon, this carbonic acid is taken up by plants, the carbon of it forming their growth and a portion of their organized parts, the

"A molecule may be explained as the smallest atom into which a simple or elementary body is supposed to be capable of being divided, and which many philosophers theoretically consider as being of certain definite forms.

HOME INDUSTRY.

Agreeably to promise, we enjoin the resolutions at a late meeting of the friends of Home industry in Rochester. Having been instructed to report them, they at least embody our own sentiments; and we see no reason to retract or alter them. We have at least no partisan views in the case.

In the present condition of society, it is idle to think of reaching the perfection of any thing. We shall be fortunate if in any case, we can reach the best possible. In respect to many things, right and wrong are intrinsic, absolute, unchangeable, and admit of no qualification; but in many cases duty grows out of circumstances; and that which would be unquestionably right and best in some cases, in a change of condition ceases to be obligatory or expedient. The doctrine of the free trade party, the peace party, the non-resistants, the no-government party, when justice is done to their principles and motives, breathe the highest philanthropy; but they seem utterly impracticable in the present state of society. We admire the generous aims of noble minds devoted to these great objects; but the loftiness of their purposes destroys the efficiency of their labors. The man who walks through the thronged streets of a city with his head turned and immovably fixed upon the stars, will be likely to strike against a post, to tumble into a gutter, or to run down many a passenger. Or if he undertakes to leap a chasm, which is too wide to be spanned by any human agility, it is not difficult to say where he will fall. Whoever would get along in the safest and best way for himself and others in the street must keep his elbows in, give as well as take, remember other men's rights, take care of his own; and while fixed in his determination to show no discourtesy, unkindness, or injustice towards those whom he meets, or who are travelling the same way as himself, and at the same time to preserve his own personal safety and progress, he must in some measure regulate his movements by the movements or dispositions of those about him. If he insists upon more of the side-walk than belongs to him he deserves to be jostled off. If he chooses to yield in every case, there will be enough, who, without compunction, will throw him into the gutter. If he chooses to step aside and remain until the crowd have passed, this disinterestedness will be fatal to all progress; and as wise as the determination of the traveller who sat down on the river's bank to wait until the waters should all flow by before he crossed.

We often admire the man, who yields his rights to others rather than maintain them against violence or oppression. This many times springs from a benevolence of the highest character, but often as mistaken as it is disinterested. If any man stood alone in this world, if his condition were not ultimately inseparably linked in with the condition of others, and if what extent no human imagination can determine, he might at pleasure make any personal sacrifices and yield any rights. But the condition of no human being living is thus insulated, and no man can yield any of his own rights without jeopardizing the rights of others, or establishing a precedent for an encroachment upon theirs. The doctrine of expediency, not in a low and contracted sense, but in the most elevated and comprehensive view, is the foundation of all right, because it is conformable to the will of God, which aims at the happiness of all men.

It would be charming indeed to see all men brought entirely under the dominion of universal love, in which every other man's happiness should be as dear to us as our own. This spirit of universal love and justice should actuate us; but how this spirit or principle will best exert itself in any particular case must depend upon the circumstances of that case. This spirit will have no other object than the production of

the greatest amount of happiness and good. But how is this to be effected—certainly not by neglecting our own to take care of the interests of other people. Our powers are at best small, and our sphere of action limited. Every man acts most efficiently in operating upon what is nearest to himself. Would a man then do most good, he must do what he can to mend himself, then to make his family happy, to provide for their welfare and happiness, and then his town and then his own country. Certainly he must violate no law of justice or kindness in doing this; he is not to seek to rise upon the oppression or injury of others; but within these rules, he must labor and can labor with success only in this direct manner. If every man should neglect his own family to take care of his neighbor's, neither would he be so efficiently or so well served as if each performed his duty to his own. In the present condition of human nature, therefore, the only principle upon which individuals or families, or larger communities, can properly act is not a mean and morose selfishness, which always leads to fraud and injustice; but an enlightened self-interest, which seeks continually to rectify wrong, to do good, to make good better and better best within its own immediate sphere. Here its powers will be most efficiently applied; here the effects of its exertions can be best watched over and controlled; and here consequently, it is bound first of all and constantly to exert itself.

Political Economy, though like every other science, very much mystified by men, who either want to make a parade of learning or else having no clear ideas on any subject, stir up the mud from the bottom when they get cleft into the clearest water, or otherwise, who want to controvert the plainest and most established principles, and instead of conforming to nature are vain enough to think they can make her conform to their notions, is as simple as domestic economy, and rests upon precisely the same principles. The best ordered and the most prosperous family is that, which seeks as far as it can without the most obvious disadvantage, to supply its own wants from its own resources within itself. If it demands the aid of others it will first be sure of the means of paying for that aid, and especially be equally certain that others will be willing to receive their pay in the products of its own industry. It will in no case encumber itself with debt, unless it be that wholesome credit for the sake of productive improvements or investments, where the provision for the extinction of the debt is sure as any thing human can be, and made when that credit is assumed. It will seek first of all to give employment to every member of its own household in the various forms to which their capacities, dispositions, or habits are best adapted, because the interest of each one is the interest of all, the duties and obligations are reciprocal and thus the productive power of all is most certainly and successfully availed of. Above all, it will spend nothing for superfluities until necessities are provided, nothing for elegancies until comforts are obtained. Then there can be no objection to the innocent luxuries and elegancies of life, where there are the means of paying for them from the surplus profits not needed or required for the equal comfort and benefit of all the members of the household. This is sometimes stigmatised as a Robinson Crusoe and selfish system. We only add that in its moral tendencies upon character, improvement and domestic happiness, it has proved itself over and over again in the highest degree salutary. Certainly it cannot be pronounced either selfish or inhuman, if we open wide the doors of the household and offer an equal share in all the domestic benefits, to every man, who is willing to throw in his lot among us; and give for the common benefit, all the advantages of his talents, service, education, knowledge and skill. This is true domestic economy and true national economy; and

thus every encouragement should be given to home industry. Without regard to any other people or country, we are bound first of all to provide for ourselves. In seeking to make our own country as industrious, as prosperous, and as independent as we can, we best serve the public good and the good of all; and on the highest principles of christianity nothing more can be demanded of us than that noble principle incorporated into our constitution, which offers our country as a free asylum for the unfortunate and oppressed and downtrodden of every land; and admits them to a full participation of all our civil and social benefits, upon the reasonable conditions of good conduct and a due subordination to the laws and institutions of the country.

The committee reported the following resolutions:

1. Resolved, That labor is the creator of wealth and the conservator of it.
2. That Government, established for the general welfare, is bound to protect and encourage the wholesome industry of its people in all its forms.
3. That the true independence of an individual, a family, or a nation, consists in its ability to supply its own wants from within itself, in the exertion of that ability, and above all, in keeping clear from debt.
4. That the interests of the whole people are one and indivisible. The eye cannot say unto the hand, I have no need of you, nor the head to the feet, I have no need of you. The poor are dependent on the rich; the rich equally dependent on the poor; the laborer on the employer, the employer equally upon the laborer; and the interests of the agricultural, the mechanical, and the commercial classes—of him whose capital is money, and of him whose capital is skill, and of him whose capital is knowledge, and of him whose capital is labor—are the same and indivisible.
5. That on every principle of public good as well as of equity, governments are bound to cultivate and strengthen the ties of mutual dependence among its people, so that the products of the skill of the one may be exchanged for the products of the labor of the other; that where such a mutual intercourse is secured against the disturbance of foreign influences, prices and values will adjust themselves to a fixed and equitable standard, and 'live and let live' will be the universal rule.
6. That to admit to an equal competition with our own, the products of foreign labor, must tend to reduce our laborers to the condition of these unfortunate foreign operatives, whose oppression and degradation compel them to toil, not for the comfort of life, but for a mean and bare subsistence.
7. That a home market ought on every account to be encouraged, as most important to our agriculture, and to all our productive classes.
8. That every article which we can produce ourselves, should either be absolutely prohibited from abroad, or admitted under such restrictions as to discourage its introduction, and to encourage its production at home.
9. That the tendency of a discriminating tariff, founded upon this plan principle, is not in the end to increase prices, but to equalize and reduce them; and even if its tendency were otherwise for a time or to a degree, the man who lives upon his money has little right to complain, since it is only reasonable that his money should be expended for the benefit of those by whose labor it has been earned, and by whose power it is protected.
10. That a trade with a foreign country to be free, should be on terms of perfect reciprocity.
11. That the restrictions upon our trade which are imposed by any foreign nation in refusing to receive the products of our industry in a fair and equitable exchange for the products of her industry, can be properly met only by an absolute refusal to receive her products at all, or by such countervailing and corresponding restrictions on our part as shall serve to equalize the traffic.
12. That holding the above principles as evident and undeniable, we respectfully transmit them to our Representatives in Congress with a request that they would so dispose of them in reference to any measures that may be taken on the tariff of duties the present session, as shall best serve the views and wishes of this meeting of the citizens of Rochester as thus expressed.

Our partial deficiency in plates this month will be compensated in the next number. Mr. Sherwood's bull did not show his horns until too late to bring him on the turf.

NITRATE OF SODA.

We are much obliged to our good friend for the subjoined communication. We are glad of the information which it furnishes on a subject which must ultimately be of great importance to wheat growers. We shall presently follow it up with more full information on the matter. He could not have made us a promise more gratifying than that he will communicate to us the earliest valuable agricultural intelligence which comes within his purview. His foreign correspondence furnishes in this respect peculiar advantages. We hope likewise to hear from him occasionally on the subject of Horticulture. No man is more competent.

Extract from a private letter.

"Being desirous to communicate to you on the subject of Nitrate of Soda, received from London by the arrival of yesterday, I also include the subjoined statement on the subject, on the chance of your not having received it.

The Gardener's Chronicle of January, edited by Lindley, contains an extract from the report made to the Bath and West of England Agricultural Society, by Mr. G. Webb Hall, and of course entitled to the fullest credence. A piece of land of which the wheat crop previous to 1838 was not worth gathering, was, in 1839, 1840 and 1841, manured with a new (artificial or compounded) manure, and each of these years sowed with spring wheat; the first year the crop was 5½ sacks per acre, weight 64 lbs. to the bushel; the second year 6 sacks, and 1841 nearly 7 sacks per acre, the straw each year extremely heavy and fine. The manure is cheap, averaging cost 20s. sterling per acre. Observe here particularly, *no rotation*, each year wheat, and each year an increased product. The manure was not named, but the man who helped to make it says it was *Carbonate of Ammonia*. On this statement Mr. Lindley observes that he does not see why Sulphate of Ammonia, which would be obtained by strewing the stables with Gypsum as mentioned in the books, would not do as well. Now Mr. Lindley is no chemist, and I differ from him in opinion, for the following reasons: When a sulphate is decomposed in any other way than by the complete saturation of the sulphuric acid by another base, fumes of sulphuric acid or sulphurous acid gas are probably created, than which gas there is nothing more injurious to vegetation, even in the smallest quantity; this has been proved by various quite recent experiments. I have lately tried *pure* sulphate of ammonia on Geraniums, which were nearly killed by it; but I do not offer this as conclusive against the sulphate formed by gypsum,—this is an experiment I should like to see tried by farmers on a large scale, and I have no doubt several are now trying it. With carbonate of ammonia both the carbonic acid gas and the ammonia are highly useful to vegetation.

Now for the Nitrate of Soda. London, 15th February, 1842. The sale of Nitrate of Soda for agricultural purposes, is pretty brisk; the price is 21s. sterling to 24s. 6d. per 112 lbs., about 2000, say two thousand bags were sold for this purpose during the month of January, 1842. The stock of this article in London and Liverpool at the end of each year, 1840 and '41, averages from 21 a 25,000 bags, a pretty clear proof that the demand for it is pretty steady, and the value of it as an agricultural manure ascertained. Saltpetre, which is used for more, and vastly more villainous purposes than for manuring the land, sells at from 26s. 6d. to 28s. 6d. per 112 lbs."

Boston, 12th March, 1842.

For the New Genesee Farmer.

Gypsum—Information Wanted.

Liebig considers urine as the richest of all excrementitious manures.

"Human urine is the most powerful:—that of

horses and horned cattle contains less [ammonia,] but infinitely more than the solid excrements of these animals." * When it is considered that with every pound of ammonia which evaporates, a loss of 60 pounds of carbon is sustained; and that with every pound of urine, a pound of wheat might be produced, the indifference with which these liquid excrements are regarded, is quite incomprehensible."†

"In dung reservoir a well constructed and protected from evaporation, [the ammonia] is retained in the state of solution; and when the putrefied urine is spread over the land, a part of the ammonia will escape with the water which evaporates; but another portion will be absorbed by the soil, if it contains either alumina or iron; but in general only the nitrate, phosphate, and lactate of ammonia remain in the ground.—The loss suffered [by the escape of carbonate of ammonia] is nearly equal to one half of the weight of the urine employed, so that if we fix it [one half will be saved.]"

To fix it, he proposes to strew gypsum over the field, and then the putrefied urine or drainings of dung hills, so that all the carbonate of ammonia may be changed into sulphate of ammonia which cannot fly away, but will remain in the soil.

He adds however, "there are still simpler means of effecting this purpose:—Gypsum, Chloride of lime, sulphuric or muriatic acid, and super-phosphate of lime, are all substances of very low price, and completely neutralize the urine, converting its ammonia into salts that possess no volatility."§

But I have not found any further directions in regard to the application of these substances. He informs us indeed, that 100 pounds of burned gypsum would fix as much ammonia in the soil as 6,250 pounds of horse's urine would yield to it; or that 1 pound of gypsum would fix the ammonia in 62½ pounds of urine. But 62½ pounds of water (1000 ounces) would only dissolve 2½ ounces of gypsum, at the rate of 400 parts of water to 1 of gypsum; and therefore we want a barrel of water in addition to dissolve gypsum enough to fix the ammonia in 62½ pounds of urine. In other words: the urine would not dissolve one sixteenth of the gypsum necessary to fix the ammonia.

How then can gypsum strewed in stables (according to Liebig's directions) which must be dissolved, to save all the ammonia that forms there?

My object in making this question is to acquire information. I have tried to understand the subject, but may have much yet to learn; and if I am wrong, I should feel grateful for being set right. I want some cheap reservoir or method, to save urine from waste; but if I must add a barrel of water to every six gallons of urine, it must be a troublesome concern, and I should prefer manure, or old lime, or even pulverized charcoal. I have no fancy for distributing liquid manures.

AN ENQUIRER.

Editorial Remarks.—Liquid Manure and Urinaries.

We are not certain that we quite understand the difficulties of our respected correspondent, as we do not understand that the gypsum must be dissolved in water in order to absorb the urine, and so fix the ammonia either in the stables, or when spread upon the ground. Of course it is supposed to be finely powdered.

Our friend knows as well as we do, that in Flanders the urine vaults are made under their stables and cemented so as to be water tight. Here it is mixed with rape dust, and carried out in tanks, often upon the shoulders of the women, and sprinkled upon the growing crops; a process, which cannot be considered as at all superior to the best *ca de Cologne* in im-

proving their personal attractions. Detestable indeed must be such practices. But better methods have been adopted, where, as I have seen, troughs or channels have been laid behind the cattle stalls; and all the urine conducted to a covered cistern or receptacle, from whence it was pumped out at intervals into a machine drawn by one or more horses, like what is used for watering the streets of Cities, and distributed over the fields. The beneficial effects in such cases have amply compensated the expenses. When designed however to be so distributed, strainers must be carefully affixed to the conduits, or otherwise the machine will not distribute it. It will bear also being diluted to some extent in the cistern with advantage.

We have likewise known a cow stall with a vault extending the whole length of it, four feet wide, and three feet deep, carefully stoned and cemented so as to be water tight. The cows were tied in the stalls every night in the year. The vault was emptied two or three times a year, being as often filled with muck or loam, which became thoroughly saturated with the urine admitted through holes in the floor. The boards of the floor were easily removed and replaced, and a large amount of most valuable manure was made in this way. This is a very homely subject, we know; and the fastidious we hope will not look at it; but there is none which more essentially concerns a farmer's interest, and scarcely less, the cleanliness and health of his premises.

Holderness Cattle and Hollow Head.

To S. St. John, who inquires about the Holderness breed of cattle, we answer that they came originally from Holland into the counties of Durham and York, in England. They were coarse and thin animals, but yielded most abundantly in milk; the milk however, of an inferior quality; the distinguished breeders of the Teeswater cattle crossed their best stock with the Holderness, and from this cross with some variations, have sprung the Yorkshire cows, which are the most celebrated in the London Dairies or milk establishments. These Yorkshire cows are, properly speaking, Improved Durhams, and therefore, many of the Improved Durhams may be regarded as abounding in the Holderness blood, the cross of the Teeswater having improved their shape, lessened in some degree their yield of milk, and given them a tendency to fatten.

The weight of the bull at three years old, which he describes at 21 to 2200 lbs., is an evidence in favor rather than against his being an Improved Durham. When he asks us to give him the marks, which show the Hollow Head, we can only say that we know nothing of this deficiency in brute animals; but poor soul! have ourselves labored under the complaint all our lives; and if he wishes to know more about it, he must surely apply to a full head for an explanation.

Mildew upon Gooseberries.

Advice from one competent to give it—"Say to the growers of gooseberries, if they wish to keep off mildew, train your bushes so as to admit a free circulation of air through them; manure about the roots; and forget not to sprinkle them with soap-suds on washing days, three or four weeks in succession before blossoming; and they cannot miss having fine, fair, large berries. I know this by several years' experience. Let them try and see."

MUNIFICENT DONATION.—Give while you live; thus secure the purposes of your charity and gather the first sheaves of the harvest.

John Conant of Jaffrey, N. H., a spirited and intelligent farmer, has given his valuable farm of 230 acres with all its appurtenances, to the Cheshire County Agricultural Society for the establishment of an Agricultural Seminary. It is not many miles from Keene. It is a noble benefaction, and reflects upon him the highest honor.

INTERESTING REPORT OF THE COMMISSIONER OF PATENTS.

Indian Corn for Oil.—Sugar from Corn Stalks.—Lard for Oil.—Silk.—Statistical Table.—Agricultural Patents.

The Commissioner has favored us with this important document. Mr. Ellsworth is entitled to the highest credit for his industry and zeal, especially in every thing connected with agricultural improvement. The report discloses enough to encourage the friends of an improved and extended husbandry, if even they may calculate upon a tithe of what is promised. Immense, however, as the agricultural produce of the country is destined to become, we fear that the picture is too highly coloured, and expectations held out which, in our humble opinion, may not be immediately realized. We acknowledge ourselves a little more than surprised at some of the statements.

We quote the following from the letter of the Commissioner:—

"The value of the agricultural products almost exceeds belief. If the application of the sciences be yet further made to husbandry, what vast improvements may be anticipated! To allude to but a single branch of this subject. Agricultural chemistry is at length a popular and useful study. Instead of groping along with experiments, to prove what crops land will bear to best advantage, an immediate direct analysis of the soil shows at once its adaptation for a particular manure or crop. Some late attempts to improve soils have entirely failed, because the vegetable, transported at considerable expense to enrich them, was already there in too great abundance. By the aid of chemistry, the West will soon find one of their greatest articles of export to be oil, both for burning and for the manufactures. So successful have been late experiments, that pork (if the lean part is excepted) is converted into stearine for candles, a substitute for spermaceti, as well as into the oil before mentioned. The process is simple and cheap, and the oil is equal to any in use.

Late improvements, also, have enabled experimenters to obtain sufficient oil from corn meal to make this profitable, especially when the residuum is distilled, or, what is far more desirable, fed out to stock. The mode is by fermentation, and the oil which rises to the top is skimmed off, and ready for burning without further process of manufacture. The quantity obtained is 10 gallons in 100 bushels of meal. Corn may be estimated as worth 15 cents per bushel for the oil alone, where oil is worth \$1 50 per gallon. The extent of the present manufacture of this corn oil may be conjectured from the desire of a single company to obtain the privilege of supplying the light-houses on the upper lakes with this article. If from meal and pork the country can thus be supplied with oil for burning and for machinery and manufactures, chemistry is indeed already applied most beneficially to aid husbandry.

A new mode of raising corn trebles the saccharine quality of the stalk, and, with attention, it is confidently expected that 1000 pounds of sugar per acre may be obtained. Complete success has attended the experiments on this subject in Delaware, and leave no room to doubt the fact that, if the stalk is permitted to mature without suffering, the ear to form, the saccharine matter (three times as great as in beets, and equal to cane) will amply repay the cost of manufacture into sugar. This plan has heretofore been suggested by German chemists, but the process has not been successfully introduced into the United States, until Mr. Webb's experiments at Wilmington, the last season. With him the whole was doubtless original, and certainly highly meritorious; and, though he may not be able to obtain a patent, as the first original inventor, it is hoped his services may be secured to perfect his discoveries. It may be foreign to descend to further particulars in an annual report. A minute account of these experiments can be furnished, if desired. Specimens of the oil, candles, and sugar, are deposited in the National Gallery.

May I be permitted to remark that the formation of a National Agricultural Society has enkindled bright anticipations of improvement. The propitious time seems to have come for agriculture,

that long neglected branch of industry, to present her claims. A magnificent bequest is placed at the disposal of Congress, and a share of this, with private patronage, would enable this association to undertake, and, it is confidently believed, accomplish much good.

INDIAN CORN MEAL FOR OIL.

It is added in the report, "that it is said that the meal, after the oil has been extracted, will make harder and better pork when fed out to swine than before. The oil is of a good quality and burns well." These are certainly extraordinary facts and we shall wait with some impatience for their verification. We should be glad to know whether the meal remaining after the oil has been extracted, is of sufficient value to pay the cost of extracting the oil; and whether, after passing through this process, it can be kept any length of time. That the corn after going through this process will make harder pork, is not improbable; but that it will make better pork is likely to depend, it may be, somewhat upon our preference for lean or fat pork. It is difficult to settle questions of animal nutrition, unless in such cases as that of Dr. Beaumont, where the patient has an open window into his stomach; but, it is generally supposed, that the oily part of the food was that which went principally to form the fat of animals. That Indian Corn should yield the farmers fifteen cents a bushel, unless the residuum is of equal value with the oil extracted, is, however, not a great encouragement to its production even on the rich prairies and alluvions of the West. Their average crop, unless with extraordinary cultivation, in Illinois, for example, is not more than forty bushels per acre; but put it at sixty, the product would be only nine dollars. Now deduct the ploughing, which is not less than two dollars; the planting not less than a dollar; the cultivation, even with a horse harrow only, not less than one dollar more; the harvesting, which must be two dollars; the husking and cribbing, which must be three dollars more; and the cost of the land and fencing, and other expenses of management, there will not be a very large profit remaining, unless we can pay for our labor at fifteen cents, or a bushel of corn per day. We say nothing of the grinding of the corn, which we know, at one of the principal mills in Illinois, costs three pence, or eighteen and three quarter cents per bushel. But domestic mills may be introduced. We are not willing, however, to say more on this subject until we know more. Perhaps, with our imperfect information, we have already said too much.

SUGAR FROM CORN STALKS.

Another great article of product spoken of in the report, is that of Sugar from Corn Stalks. "A new mode of raising corn, trebles the saccharine quality of the stalk." This is certainly an extraordinary discovery. The stalks of corn, if gathered before the ear is formed, it is here stated, yield of saccharine matter three times as much as the beet, five times as much as the maple, and fully equal, if they do not exceed, that of the ordinary sugar cane in the United States. "One thousand pounds of sugar, it is believed, can easily be produced from an acre of corn. It has been ascertained, by trial, that corn on being sown broadcast [and so requiring but little labor, comparatively, in its cultivation,] will produce five pounds per square foot, equal to 108 tons to the acre for fodder in a green state; and it is highly probable that when subjected to the treatment necessary to prepare the stalk, as above described, in the best manner for the manufacture of sugar, a not less

amount of crop may be produced. Should this prove to be the case, one thousand weight of sugar per acre, might be far too low an estimate. Should the manufacture of sugar from the corn stalk prove as successful as it now promises, enough might soon be produced to supply our home consumption, towards which, as has been mentioned, at least 120 millions of pounds of foreign sugars are annually imported, and a surplus might be had for exportation."

These statements may well be called startling; but we must be pardoned if we consider them, in some measure, of the *multum in parva* variety. We have a high respect for Mr. Ellsworth; we believe there is not a letter officer in the government; and that no man living would be more reluctant to make a misstatement than himself. But we want a good many more facts and experiments in the case, before we can yield entire confidence to such predictions. The whole, for aught that appears, grows out of a statement of a Mr. Webb, of Delaware, given in our November number, who obtained from a small piece of ground at the rate of 100 lbs. of sugar to an acre, and who states that further experiments showed conclusively that the produce might be increased ten-fold. Now we have no desire to question Mr. Webb's veracity; but it will be observed in the first place, that he has not yet obtained 100 lbs. to an acre, but only at that rate; and in the second place, that although experiments to him have conclusively shown that a thousand pounds may be obtained to an acre, yet we do not know what those experiments were, and the conclusion is matter of inference or private judgment. We shall be exceedingly glad to be set right on this subject.

The calculation of producing green corn fodder at the rate of 108 tons to an acre, is, we believe, more easily asserted than proved. We should like facts in this case much better than conjecture.

Tall meadow oat grass has yielded, green, at the rate of 16,325 lbs. per acre, and dried, 5717 lbs. Millet has yielded, green, at the rate of 12,251 lbs. per acre, and when dried, 4747 lbs. Herds grass, when green, 40,837 lbs., and dried, 17,355 lbs., or when cut after the seed is ripe, 19,397 lbs. A crop of Herds Grass producing when cured, 17,355 lbs., is indeed enormous; and what very few among us have ever seen, less than five tons being the largest measured crop, which has come within our knowledge. We have never known a crop of green corn fodder weighed, when cut for fodder, but we have given in our last No. the weight of an acre of corn fodder of the gourd seed variety, when cured, including husks, and yielding 66 bushels of grain per acre, and the whole amount of that was 2 tons, 13 cwt., 13 lbs. In the case of herds grass, the proportion of green weight bore to the dried as 46 to 17 or as 20 to 8 tons. If we may infer any thing from this fact in regard to Indian Corn, we may reckon the green fodder from such a yield of corn as 6 to 7 tons. It would, however, be much more than this, if the corn had been sown broadcast; and perhaps may be quadrupled. Conjecture, however, is idle in a case where, we hope, we may soon have facts. It is supposed in the case of the Report, that the corn is to be sown broadcast and yield at the rate of five pounds to a square foot. This is a remarkable calculation; and if corn is sowed thus thickly, how is it to be got at to pluck off the ears, which is said to be a necessary part of the process? A few months however, will settle this; and if an acre of corn, by the mode described or any other mode, can be made to yield five hundred pounds of sugar, we

shall throw our hat up as high as any one in the crowd.*

LARD FOR OIL.

Another prospect held out to the farmers is, that of converting their lard into oil and candles. Lard has been used by many persons for lights, and has been adopted, it is said, in the light-houses in Canada on the Lakes.

"But it has now been discovered that oil equal to sperm can be easily extracted from lard, at great advantage; and that it is superior to lard for burning, without the necessity of a copper tubed lamp. Eight pounds of lard are equal in weight to one gallon of sperm oil. The whole of this is converted into oil and stearine, an article from which candles, that are a good substitute for Spermaceti, can be made. Allowing then for the value of the stearine above the oil, and it may be safely calculated that when lard is six cents per pound, as it is now but four or five cents at the West, a gallon of oil can be afforded there for fifty cents; since the candles from the stearine will sell for from twenty-five to thirty cents per pound." Now we are not certain, though we have read this passage several times, that we understand the elements of this calculation.

The quantity of oil obtained from eight pounds of lard is not stated, nor the quantity of stearine. But oil and stearine in sufficient quantities, as we understand the statement, can be obtained from eight pounds of lard to pay for the manufacture and to produce a gallon of oil equal to sperm oil, and of the value of 1.50 cts.; and as this comes from eight pounds of lard, the actual cost is only the price of the lard, 48 or 50 cents. Under such a process, how long may it be calculated that oil will remain at 1.50 cts. per gallon, or spermaceti candles at 25 to 30 cents per pound? This certainly, if we understand the statement, and we are by no means certain that we do, is sufficient encouragement to make our hogs all lard if we can so contrive it; and especially, if it can be done upon corn after the oil has been extracted. (See above, page 54, column 3, line 8.)

OIL FROM CASTOR FEAN.

The Report refers in the next place to the extraction of stearine from the castor bean, which is said to have been successfully practiced at Alton in Illinois. We hope some of our friends in that region, if perchance they should see our humble sheet, will give us without delay some information on this subject.

SILK.

On the subject of **SILK** the Report presents, it must be admitted, some golden prospects. The fact that in one year our importation of silk goods exceeded 20,000,000 dollars, is very often referred to in discussing the subject of silk growing; but we believe the average import for several years has not much exceeded from seven to twelve millions. In 1839-40 it little exceeded ten millions. This is just ten millions too much. The Report calculates that "should one person in a hundred of the population of the United States produce annually 100 lbs. of silk, the quantity would be nearly 18,000,000 pounds, which at \$5 per pound [and much of it might command a higher price] would amount to nearly \$90,000,000, nearly \$30,000,000 above our

*Since penning the above, we have seen it stated in some exchange paper, that forty tons of green corn had been obtained from an acre in Worcester Co., Mass.; and at a late agricultural meeting in Boston, the editor of the New England Farmer is reported in the Ploverman to have said that he understood that 100 tons of green corn had been cut from a single acre in three cuttings, in a season, and he had known 37 tons cut on an acre at one time.

We have no disposition to impugn these statements in the smallest measure; but we should be exceedingly glad to know when and where these crops were produced; and how and when the amount was ascertained.

whole cotton exports, nine times the value of our tobacco exports; and nearly five or six times the average value of our imports of silk." This is what we call dreaming with one's eyes open. How can sober men indulge in such calculations as these? What sort of a population have we that one in a hundred, of the three millions of slaves too, shall produce one hundred pounds of silk each annually, or at that rate; and who can suppose that if we should produce 18 million pounds of silk, that it would retain its price of five dollars per pound, or indeed one half of it? Why we should have to carpet our rooms with it and use it for dish-cloths.

But we found no difficulty in accounting for this flight of the imagination in the Report, when we came to look at the statistical tables obtained by estimate, for 1841. Here it is said that in Massachusetts there were produced in the year 1841,—198,432 lbs. of silk cocoons. Now we believe that in the whole of Massachusetts there are scarcely mulberry trees enough to feed the worms that would be required to produce half that number of cocoons. But we are not without light in the case; and there are some facts which may wake us up and bring us to our senses, if it is possible that we have relied upon the returns in these statistical tables, obtained by estimate.

"A law was passed in Massachusetts in 1836, allowing a bounty of one dollar for every ten pounds of silk cocoons produced in that state. Under that law, the whole amount which claimed the bounty, and this included likewise, all that were reeled or thrown for four years from 1836 to 1840, both inclusive, was 11,000 lbs. 1 oz., and of reeled and thrown silk, 757 lbs. 8 oz.; and in 1841, as returned by the United States census, the whole amount of silk cocoons produced in Massachusetts that year, was 1,741 lbs, which is undoubtedly much below the truth. But for 1841-2, we have the authentic return to the Secretary's office of silk cocoons claiming the state bounty, from 10th of February, 1841, to 29th of January, 1842, amounting to 27,219 lbs. 5 oz., and 1390 lbs. 4 oz. of silk reeled, which is included in the above cocoons. This indeed is a most remarkable and encouraging increase, but 27,219 lbs. does not look much like 198,432 lbs. We know Mr. Ellsworth would make no mistatement nor willingly be imposed upon, with all his enthusiasm for agricultural improvement; but we are sorry to see Mons. Tonson, of multi-causal memory, come again.

STATISTICAL TABLES.

The Report presents a great many statistical tables of agricultural products obtained for the year 1841, by estimate.

We would not be captious or fastidious in the case. We think statistical knowledge of immense importance. But at the same time we have little confidence in returns which rest upon estimates and not upon actual inquiry. Take again the case of Massachusetts, in the article of wheat. In the return here for 1841, the amount is put down at 189,571 bushels. Now in 1838-9, when, on account of the bounty perhaps, more wheat was sowed in Massachusetts than in any one year before, the returns to the Secretary's office amounted to 103,570½ bushels, from which 45½ bushels were to be deducted for wrong returns. As the bounty was not given where less than 15 bushels were raised, there was some amount which was not returned; but it could not have been large. In 1840, as by the U. S. census, it amounted to 153,923½ bushels. There is no reason to suppose that the production has increased. There are

many other returns which, as they do not agree with information which we deem certain, we consider as erroneous. Most certainly there is no intention to misstate; and no wilful error; but judgment and opinion, or as it is termed, *estimates*, are extremely uncertain in all matters of statistical information, and there can be little hope of accuracy until Congress create a bureau or department or commission for this very object; ask returns from the States, and the States on their part by a very simple legislation, co-operate with Congress in obtaining, with all practicable exactness from year to year, this most desirable information.

AGRICULTURAL PATENTS ISSUED IN 1841:

Of the patents issued the last year for agricultural machinery, the following are among the articles:—

- | | |
|--|--------------------------------------|
| 4 Bee Hives, | 7 Ploughs, |
| 2 Churns, | 6 Seeding and planting machines. |
| 5 Corn Shellers, | 13 Snut Machines for cleaning grain. |
| 2 Cultivators, | 1 Straw Cutter, |
| 2 Hulling and Cleaning machine for clover seed, rice and grains, | 2 Threshing Machines. |
| 2 Mowing and Harvesting machines, | 1 Winnowing and Fanning Machine. |
| 2 Improvements in Scythes and Smiths. | |

The Report contains much other valuable matter to which we mean to revert hereafter.

For the New Gloucester Farmer,

Anti-Mousology.

There is perhaps no animal more pestiferous to the farmers than rats and mice. They sometimes destroy his seed when sown, prey upon his crops when growing, and when they are carefully secured after many a day of tedious labor in the barn, granary or cellar, they are sure to insinuate themselves into his repositories to feed upon and recklessly waste his substance. Even winter, with its penetrating frosts and piercing winds does not retard their movements, nor does summer with its sultry suns diminish aught from their labors. When deep snows mantle the earth, they will, unless precautionary measures are taken to check their labors, bark and destroy his young fruit and shade trees, and then, when spring comes on, with its genial suns to warm his heart into new efforts of taste and utility, it sinks coldly within him, and he often relinquishes his labors in the horrors of despair. By stamping down the snow around young trees and shrubs, the wholesale vendors of mischief may be nonsuited. The best way of banishing them from mows or bins of grain, and all similar places, we ever heard of, was scattering the branches of mentha viridis or common spear mint about in the rows when packing away grain, or strewn it over the bins of grain, casks of apples, &c., exposed to their depredations. We have tried it, so have our neighbors, and found it to be effectual.

W. B.

Mount Oseola, Feb. 1842.

Squash Culture.

This does not differ essentially from the culture of cucumbers and melons. Where they have too much tendency to form vines, which materially affects and diminishes the growth of the fruit, it is an excellent practice to break off the end of the vines, and hoe earth over it, thus diverting the juices of the plant from the growth of the vine to the fruit, thus increasing its size, and at the same time, preventing the stalk from running over an undue quantity of land.

We find baking the best method of cooking winter squash for our palate, especially the green Valparaiso. The process of baking requires no more labor than boiling where cooking stoves are in use, and the flavor of them is much increased, so as to resemble that of sweet potatoes.

W. B.

Mount Oseola, 1842.

ROCHESTER, APRIL, 1842.

To Readers and Correspondents.

We must claim indulgence. We have several valuable agricultural addresses and communications from valued friends and correspondents, which we cannot more particularly acknowledge in this paper.

We thank D. P. K. for the Transactions of the Essex Co., Mass., Agricultural Society, always valuable and instructive.

We acknowledge "The Muck Manual for Farmers" from its learned author, S. L. Dana of Lowell. We shall give an extended notice hereafter. We are confident, from a partial examination, that it is the most valuable contribution that Science has yet made to American Agriculture, and will take rank with the best publications of European learning and skill. We are happy, as far as we have read, to find a perfect confirmation of our own heretical views on several subjects. The style is transparent; and the information practical; just as they should be.

We have to thank a Canandaigua friend and a dozen others for very kind letters. We should have been home-sick without them. There is nothing like patting a boy, who wishes to do well, upon the head and giving him a hand when he is almost up to his chin in trouble; instead of giving him a kick and telling him to go to the d—oga. Some people may think we meant to have said a naughty word here, which we might have caught in Rochester, either at meeting or in the streets; but we did not, certainly; it is only an impediment we have in our speech.

To G. K., Geneva.—We shall be very glad of the plates of the Cotswold sheep, and promise to do them justice. Let us know what to say of his Berkshire pigs.

A correspondent in Ohio inquires "what will Mr. Allen take for a pair of his Berkshires?" Mr. Allen is in Buffalo, and we in Rochester, only 80 miles apart, and 80 miles nearer to him than to us. This honest inquirer ought to have a patent for his remarkably direct mode of doing business. Would he not like that we should send him our Farmer by Pomeroy's Express, via Boston and New York?

The subject of Madder is necessarily excluded by the length of the article on Hemp, which we commend to those interested.

S. W. on Tariff and Home League, J. E. M. on Agriculture, H. P. on Corning, two communications on Ploughing Matches, E. S. on Domestic Industry, E. B. on Bail, C. L. G. W. and others on Education, R. S. C. on Schools, M. A. on Winter Agricultural Meetings, W. G.'s corrected Statement of his Views, J. J. T. on Dials, &c., W. S. T. on Bees; and several others, are respectfully acknowledged and under consideration for the future.

Two articles on Threshing Machines will be more seasonable three months hence, if Heaven sends the manna.

The large Hog from Clyde, is in pickle for the next number.

We beg F. B. to let us know where we shall return his fifty cents, which we are anxious to do, together with his very gracious and courteous letter addressed to us.

"I heard a little lamb cry, ha!

Said I, you have lost your mam-a."

Some few small Inquiries.

The Secretary of the Wisconsin Agricultural Society, in a very polite letter, postage paid, very modestly says,—“I wish to know, (an inquiring mind is always to be commended)

1st. "The number of souls engaged in agriculture in your state?" We believe there are a good many more bodies than souls, or we should double our subscription list. Look at U. S. Census.

2d. "The number of acres of arable land occupied for agricultural purposes, and the estimated average value per acre?" A very pretty calculation this, to get the average value of land in a territory 500 miles in length, presenting every variety and diversity of soil and situation as it respects climate, products, market, &c. Will this Secretary please tell us what is the average weight of the inhabitants of Wisconsin taking all the men, women and children together; and please add how large is a piece of chalk?

3d. "The various kinds and aggregate amount of the agricultural products of the State for the year 1841, and their value?" The Census of the United States for 1840, which embraces this information, cost the labor of several thousand men and several hundreds of thousands of dollars. Probably in Wisconsin, being a territory, they never heard the census was taken. It can only be a trifling affair to get it for the little State of New York for 1841, and we shall set right about it and will forward a copy when completed. In the mean time, let him go to the Commissioner of Patents.

4th. "The most important and striking results of those associations formed for the purpose of promoting the agricultural interests throughout the state?" Come to our 30 agricultural shows next autumn, and see for yourself. It will not do to boast.

5th. "Whether agriculture has received any legislative aid; and if so what, and what effect such aid has had upon that interest?" New York appropriates among the several counties \$6000 dollars per year, divided according to their population, and given upon condition that each Society raises as much as it receives from the State to be bestowed in annual premiums for products, crops and animals. She gives a certain amount to the State Society for the same object. She gives likewise, a small premium on cocoons and raw silk. Agriculture is next to education her great interest. Instead of \$8000 she should give \$50,000; but at present, like her sister states, she has found a large hole in her purse, her shoes are down at the heel; and some propose that she should take advantage of the bankrupt act. It is hoped the little thing will get her spirits again, when the ugly ditch, where she has dropped so much of her money, is filled with water. Now, in the expended state of her public improvements, she seems to be in the condition of the man who undertook to descend the shaft of a deep coal mine by the rope. Before he got to the bottom he found himself, in an agony of terror, at the end of his rope. There he hung, with his legs doubled up, incapable of returning, and feeling that when he let go his hold certain destruction awaited him. The poor fellow, in this dreadful condition, deplored his folly, said his prayers, thought of his wife and children, and when he could hold no longer, shut his eyes—gushed,—dropped—and fell about three inches.

6th. "What effect has been produced upon the agricultural interests by the Tariff; and what, in your opinion, would be the operation of imposing a countervailing duty upon goods from those countries that impose a duty upon our exports of grain, &c.?" Ask Mr. Clay, Mr. Hudson, Mr. Calhoun, the Secretary of the Treasury, or Gen. Tallmadge of New York. These are all gentlemen of *entire leisure*, and would doubtless feel much honored and most happy to answer these inquiries.

7th. "What per centum of tax is imposed upon the capital invested in agriculture in your state; and in what manner would it be proper, in your opinion, for the legislature to grant aid to the agricultural interest?" In respect to the first, there is no specific or direct tax upon agricultural capital. In regard to the second, we intend to make this a special subject of consideration in the Farmer. We hope to hear from many of our correspondents in relation to the same matter, and should be highly gratified with the opinions of the Wisconsin Secretary.

In conclusion we respectfully advise that in the mean time the Wisconsin Agricultural Society should subscribe for 1000 copies of the New Genesee Farmer, and we will in such case give them our best notices on all the very trifling subjects proposed. Did the Secretary of the Wisconsin Agricultural Society ever hear that any body in this world ever had any thing to do besides eating his dinner and smoking his pipe?

"Ladies Saloon."

Positively no admission for gentlemen."

Zelia, came very near a breach of promise. Don't be late on the great occasion. Still incognito! We shall soon have a Junius excitement about you.

Here's a bevy of lasses! opening in beauty like the flowers of spring; full of sentiment, enthusiasm, poetry. "O! the days when we were young."

Flora has our respect for excellent sentiments, well expressed, of which we shall avail ourselves. Imagination is not wanting; but her rhyme flutters upon one wing. Her secret is safe; and let her often show "Mercy."

Sarah! you are a rogue. Stand up for the farmer's industrious daughters. They are the jewels of the land. Lift up your veil; and don't set us running after a "will of the wisp." We should like to see your milk pails and pails, your churns and cheeses.

Annette is too personal; why should you *pun*—ish an unfortunate youth in that style? The motto on the seal "a hand to give and a heart to forgive," seems a sort of "Return Jonathan." "The deadly arrow remains in the side." O, cruel, cruel, Barbara Allen!

The letter from Helen, referred to last month by Adolescents, was not seen by us until after the receipt of Annette's letter. It is the one published in the Farmer last September, page 141, on Female Self-Education. We have read it, and deem the inquiries highly reasonable and important. We have partially answered them in our reply to Adolescents; but will say more when we have more leisure. Such an inquiry is not to be dismissed with the brush of a pen.

The pretty lines from J. L. are accepted, with the exception of the two last stanzas. There the nag evidently broke his trot and got into a shuffle. A tighter rein, and a little more uprightness and firmness on the saddle, the certain result of skillful practice, and the plate is won.

The Weather.—The King Apple.

[In a letter from Cayuga county.]

Foretelling the weather—or rather guessing at it—is a common practice in this country. It serves to amuse a vacant moment. It would be quite a privilege indeed, for him that works in the open air to foreknow just when he might be pelted by the pitiless storm,—for according to the proverb, "forewarned, forearmed"—with a great coat or umbrella.

It was said in ancient times that no man was ever caught in a shower without due notice of its approach, so significant are the phases of the atmosphere; though in some countries without doubt, the indications of change are more certain than in other countries. Immigrants in this region of lakes and inland seas, often complain of the uncertainty of the weather; "there's no telling;" but after a time they get nearly as much

wisdom as their neighbors, "be the same more or less."

I admit that we may often judge with some correctness of the weather for the present day; possibly we may make a good guess in the evening of what will happen to-morrow; but the third day is entirely beyond our reach. *Not one of your readers can foretell the weather for three days in advance.* I may startle them indeed; but if they think I am wrong, let them bring the matter fairly to the test. Let two or more of them agree on what shall happen, and reduce it to writing. I give the form of such a minute, to be altered according to circumstances:—*Three days hence, the sun will rise without a cloud—mild and pleasant—in the west. In the afternoon, a snow-squall—then clear, succeeded by a sharp frosty night.*

"O, we can't be so particular as that." Well, how particular can you be? "Why we can tell whether it will be likely to rain or snow within a week or so." Yes, that may be well said in a rainy or snowy climate without adding much to our stock of knowledge; but you cannot tell the quantity that will fall. You cannot tell, for instance, when one of your friends comes a hundred miles in a sleigh to see you, and the snow goes off, how long he must wait for good sleighing to return; nor whether it would be better for him to stay a few days longer, or procure a wagon and go home. All our knowledge of the third day hence amounts exactly to nothing; and the sooner we become satisfied of this truth, the better it will be for us,—for we shall then not be disappointed, but prepared to take the weather as it comes.

Vague and indefinite pretension is a mere cloak for ignorance; but I believe that many persons are not aware of the deception that they practice on themselves. Numerous are the rules for determining the weather that is to come; and many who adhere to them, believe in their correctness; but this could not happen if they kept accurate records. They forget their failures, and only remember their successes. It would be strange however, in our variable climate, if they did not *hit* sometimes; and when they do so, that satisfies them. Two *misses* to one *hit*, has no permanent effect on their credulity. They console themselves with thinking that all signs fail sometimes—or the miss was merely accidental—or they came very near it—or something else.

All the rules that I have heard for judging of the weather, are entirely fallacious; and founded on no cause capable of producing such effects. The moon has been credited on this score to a great amount; but accurate registers, kept in one place for fifty years, and in another place for thirty years, show that she has nothing to do with the matter. The rules called "Herschell's" are spurious; and our observations have proved them to be utterly worthless.

Some judge of the weather by the aspects of the new moon—whether the points are turned up to hold the rain, or turned down to let it sprinkle us. Now all this depends on the relative positions of the sun and moon, easily calculated by any astronomer fifty years before-hand. The moon never strays from her orbit. But to show that all such rules are unfounded, it is only necessary to remark that one tract of country is deluged while another is suffering from drought. While we were parched the last season, the country 200 miles south of us, had rain in abundance. "We have had a wet summer," says a correspondent in that quarter, "except in the beginning of the sixth month. In the eighth month the water issued from the sides of the hills along the roads, as it does in the spring of the year." Now it is always raining or snowing on some parts of the earth, and always dry and parching on some other parts. All such rules must therefore be nonsense, and nothing else. Can the moon make wet and dry at the same time? It is absurd

for both often occur on the same meridian, or in the same latitude, and not unfrequently even in the same country.

Some say the last Friday in the month is the index of the weather for the next month. Why should it be so? There is no reason why. This notion, founded on nothing but a whim, could only have originated in the most deplorable ignorance; and its adoption is a proof of the grossest credulity. It has not even the plausibility of witchcraft, and is unsupported by either sound sense or observation.

Many judge of the mildness or severity of the coming winter by the shape of a hog's melt (spleen). If that viscus had been moulded by the weather that had come when the animal was living, it would be odd enough—as odd as if the weather had given a new shape to their own noses; but that heat or cold which has not been felt, and had no existence at the time, should give it form, exceeds all credibility. It reminds me of the auspices of ancient Rome, and deserves no more credit—fit only to be entertained by the worshippers of idols.

N. B. The preceding remarks have no reference to scientific investigations of atmospheric phenomena.

The King Apple is a winter fruit; and was brought to this place from Tompkins county, though I believe it was previously cultivated in some other parts of this county; but I have learned nothing of its origin. It appears to be a good bearer. The following description may assist in identifying it:

Fruit large, or middle sized, roundish or conical, inclining to flat. *Eye* small, closed, in a narrow shallow basin. *Stalk* an inch long, set rather deep in a wide cavity. *Skin* a light yellow on the shaded side, streaked or blotched with red next the sun, and where much exposed, passing into a full red, sparsely marked with brown dots near the stalk, but more thickly dotted near the eye. *Flesh* whitish yellow, subacid but more sweet than that of a fine flavor.

For the New Guinea Farmer.

Comparison of the Devons and the Short Horns.

MR. EDITOR—

In a late number of your valuable paper, "A Subscriber" enquires how the farmer, in view of the conflicting opinions with regard to different breeds of cattle, can arrive at correct conclusions respecting the best breeds, both for the farm and the dairy?

Permit me, having had some experience with the Durhams and Devons, to give my views of the two breeds of cattle. Both are unquestionably excellent kinds of cattle, the rearing of which has been too much neglected.

I should be much influenced in a choice by location. If in the Western part of New York, Ohio, Kentucky, or Tennessee, I should prefer the Short Horned Durhams, for the following reasons:—in a grain growing country, or one well adapted to the culture of roots, the Durhams would be best; for they are a large breed of cattle, and require good keeping, and more time to mature than the common kind; and their size is, I believe, much increased by warm stables or climate and good feeding, for they are generally in the hands of those who take the best care of them.

So far as my experience has taught me, they do not endure the cold weather of middle New York, as well as our common cattle, nor equally fatten on grazing, at two or three years old.

I have not seen them used as working oxen, and cannot, therefore, speak of them in that capacity; as milkers, I consider them good as to quantity, though not above the common cattle, with the same treatment.

But for the New England States, and the northern and middle parts of New York, I should prefer the

Devons; for they are less in size, are finer boned and closer made; will thrive well on less strength of food, are easily kept on hay, mature younger, are very hardy, and prove well for the slaughter at two or three years old. For working oxen I have seen nothing their superior in the New England States; for they are tractable and active, unsurpassed in color, no easy to match and of good size.

With full blood Devon cows I have had but little experience; but the half breeds are excellent in size, shape, and color, and their milk rich, though not large in quantity. I think our common cattle much improved, both as working oxen and as cows, by a cross with the Devons.

Having thus given my opinions, very briefly, upon both kinds of cattle, I would, in conclusion, request any of the subscribers to your valuable paper, also to state their experience respecting the Durhams and Devons. It is only by a mutual interchange of opinions, that truth is elicited and promulgated.

December, 1841.

A SUBSCRIBER.

Editorial Remarks on the above.

We owe an apology to "A Subscriber," for delaying the publication of his article. One reason is that our paper has of late been so bristled with horns, that we feared many readers might be deterred from approach. A better reason is, that his communication is not satisfactory, especially as it was without authority; and we regret that, now we have the authority, we are enjoined to withhold the name.

The question on which he pronounces so confident a judgment is a debatable one, involving some feeling and many interests. We want then facts, not mere opinions. In this case, for example, we want to know how many of the Durhams or Devons he has owned or bred, and how long an experience he has had with them, what was their pedigree, what their ages, what their weight, how they were fed and how managed? We want to know likewise, in regard to the Durham and the Devon cows, or the mixed race, what was their actual product in milk or butter. The pail and the churn are the only tests, which we admit, of the character of a cow.

In some respects, his judgment is entirely opposed to the prevailing opinion. He speaks of the Durhams as coming late to maturity. A point for which their advocates most strongly value them, and we think with apparent reason, is their coming early to maturity.

He says the Devons will thrive well on "less strength of food." The Durhams are larger animals; and size, though not always, yet generally requires a proportionate amount of food. But excepting this, we doubt whether the Devons will do better on hay only than the Short Horns. That the Devons are more hardy must probably be admitted, as high bred animals, such as the best Short Horns, require peculiar attention and care to keep up their condition.

We have seen some admirable oxen of very high blood of the Improved Durham; but we can hardly expect to find any cattle which, as working oxen, surpass the Devon and their crosses. In general, animals of moderate size and snugly built are better working oxen than those which are large and heavy.

As milkers, many of the advocates of the Improved Durhams admit that a cross of the Durham with the Devon is an improvement, as it respects the milking properties of either race. We have seen excellent results from such a cross.

Tomato Figs.—These are certainly a luxury—one which comes within the reach of all, for every man who can put down pork for his family use, can put down a jar of them, and by so doing the utility of *tomato pills*, which now rank so high as a *newspaper medicine*, will be superseded, for in preparing the figs the medical qualities of the fruit are all concentrated. At the South they are already in high repute. And at the North too, as far as they have been tried. W. B.

Hemp.

To the inquiries of T. R. B. in regard to the cultivation of Hemp, we are happy very fully to respond in this number of the Farmer; in a way which, we trust, will be satisfactory to him.

The report of the Commissioner of Patents gives the amount of flax and hemp produced in the United States as amounting to 101,183 tons. But it is a curious circumstance and adopted in some degree to abate our confidence in these tables, that in the returns obtained by the United States census, in the first place the two articles are not distinguished one from the other, so that there is no possibility of determining how much of flax or how much of hemp was raised; and in the next "the amount is sometimes given in tons and sometimes in pounds, so that it is not always easy to discriminate between them;" that is, as we understand it, it is not known whether the figures of the Marshalls mean pounds or tons, which to be sure would make some little difference in the result. Officers employed by the government and paid for obtaining returns who have not knowledge enough or are enough to distinguish between tons and pounds, certainly deserve a vote of thanks from Congress with brass collars for their exactness. The Commissioner says that probably more than half the whole amount must be allotted to flax, as but little hemp, comparatively, is known to be raised. He says again "that some of the amounts should rather have been credited to pounds for flax than to tons, as more nearly corresponding to the actual condition of the crops in our country."

Heads, that "Kentucky probably ranks the highest with respect to the production of hemp. The crop of 1843 was a great failure, and that of the present year suffered from the dry weather. There is not so much attention paid to the culture of this article as its importance demands; yet there is every ground of encouragement for increased enterprise in the production of hemp from the supply required in our own country. The difficulty most in the way of its success, hitherto, has been the neglect either from ignorance, inexperience, or some other cause, properly to prepare it for use by the best process of water-retting. The agriculturists of our country seem, in this respect, to have been so yielded to discouragement. The desiderata of some new and satisfactory results on this subject will be seen from the fact that it is stated the annual consumption of hemp in our navy amounts to nearly two thousand tons; besides which, the demand for the rest of our shipping is not less than about eleven thousand tons more; making an aggregate of nearly fourteen thousand tons—the price of which is paid from \$220 to \$250, and by some even as high as \$280 per ton, together with other and inferior qualities, which are used to supply the deficiency of the better article. Our hemp, it is further stated, on high authority, when properly water-retted, proves, by actual experiment, to be one-third stronger than Russian hemp, to take five feet more run, and to spin twelve pounds more to the four hundred pounds. When so much is felt and said on the increase of our navy prospectively, it is an object worthy of attention to secure, if possible, the production of hemp in our own country, adequate to all our demands. The introduction, too, of gunny bags, and of Scotch and Russian bagging, and iron hoops for cotton, renders this direction of the hemp product more necessary and important. It is hoped that some process of water-retting, which will prove at once both cheap and satisfactory, may yet be discovered."

We subjoin first a letter from John Wilson of Deerfield, Mass., on whose intelligence and experience, so far as it has gone, entire reliance may be placed; and I have great pleasure in adding a letter from Henry Clay, of Kentucky, on the same subject, with which I have been recently honored. Mr. Clay has ever distinguished himself as the devoted and inflexible friend of domestic industry in all its departments; and his own improvements in agriculture and his enlightened zeal and labors for the advancement of this great interest, are not among the least substantial benefits which he has rendered to his country, in a life devoted to her honor and prosperity.

Letter I.—From John Wilson.

Deerfield, Feb. 11, 1842.

MR. COLMAN—

MY ESTEEMED FRIEND—Your letter of the 5th came to hand yesterday: with pleasure I will answer your inquiries in relation to the culture of hemp, so far as I am able. I thought I could find my memorandum on the subject of hemp, by the help of which I should have been able to give you much valuable information on the subject, but I cannot find it. I must therefore, do as well as I can from recollection. Not having expected to have my attention called to the subject again, I have forgotten much that might now be useful, though I should feel a confidence in myself to manage its culture in all its parts, were I to go into the business as I once did. In 1830 I was very largely interested both in raising the crop and purchasing hemp in the stalk by the ton,* for retting and dressing by a machine for market; this then being a new business, we suffered much and learned much, which might be turned to a good account now were I in the business.

I will proceed to answer your questions. 1st, What is the proper soil? Perhaps no soil in the world is better adapted to the growth of hemp than the tillage land in the meadow in front of your house at Meadow Banks, or much of the rich tillage in Deerfield meadows, or on my old farm on the Connecticut. The soil on the Genesee River I should consider well adapted to hemp; in short it wants a warm, deep, rich loam, just suited to the growth of Indian corn. What are the necessary preparation, manure, &c.? That land which has been in Indian corn, potatoes, or any other spring crop the last year, may be prepared for hemp. The land should be well manured with any kind suitable to plough in for corn, (I never saw too much put on) the land should be ploughed and harrowed two or three times, to reduce it to a fine tilth—rolling is very useful to crush the lumps.

The time of sowing, quantity of seed, preparation of seed, drills, hills or broad cast? From 20th of May to 1st of June (here). I suppose your seasons will not vary much from ours. Two bushels to the acre is the usual quantity of seed, and it should be of the last year's growth—try it before sowing, old seed will not vegetate well—very rich land will require more; no preparation of seed required. Sow broadcast, and be sure that the seed is equally distributed over the surface, I have practised sowing a part of the seed one way, and the remainder crosswise. The seed should be covered with a light harrow, and were it not that the hemp pulls harder, I should prefer rolling after sowing.

The after culture, and whether the male plants are gathered before the female plants, &c.? The male plants are not gathered before the female plants for the fibre; both are pulled together soon after the male casts its furrow, before the seed is ripe; the male ripens first; when the male stalk turns yellow and drops it leaves, both are in a fit state to pull. For raising seed a piece should be set apart expressly for that purpose. I practiced sowing in drills: rows about two feet apart, three or four inches between stalks I should think a proper distance; they should be hoed; the male stalks should be taken out after casting the furrow; in this open culture the female plant grows very large and branching; before it begins to cast its seed it should be cut by the ground, and after lying long enough to wilt, should be tied in small bundles and a few set together, open like shocks of corn, to dry; when dry let it be carefully carried to a threshing floor on the ground or to the barn, where, if dry dry, it should be threshed. Fifty bushels of good seed are sometimes produced to the acre; after cleaning the

seed in a winnowing mill, it should be spread in a lot to dry.

The time and mode of harvesting? As before stated, when the stalk of the male hemp begins to turn yellow, after casting its furrow and its leaves principally shed, the hemp is in a proper state to pull; this is done in the same manner as of pulling flax, each hand taking a work wide enough to spread his own hemp on after him; the hemp, after lying a day or two in good weather, should be taken up and bound with straw in small bundles, and set up in small open bunches to dry, the sheaves should be well bound or by often handling they will get loose and open; after the hemp is perfectly dry, it should be either housed or well stacked in the field for retting. Standing out exposed to dews and bad weather, gives the hemp a dark color and is not so good.

How retted and broken and prepared for market? About the 1st of September,* the hemp should be packed down in a pond, and boards or rails put across the handles with sufficient weight on them to keep the hemp under water, here it is to remain till it is sufficiently rotted to separate the fibrous from the ligneous part of the stalk; from 4 to 6 weeks, according to the temperature of the water, will complete the process. To know when it is in a proper state to take from the water, small parcels should be repeatedly taken out, dried and put under a break like flax; when it is found to be in a proper state, the water should be drawn off and the hemp drawn out on sleds and set up against fences or poles, put up on crotches, to dry; here it may stand without injury during the winter, or be dressed out like flax at any time when it can be dried; if it is to be dressed by hand, which I should prefer to any machine that I have seen, it requires a break much coarser than for flax, breaking the woody part of the stalks coarsely, they separate from the fibres in dressing much easier than if broken fine; after breaking and shaking out what shives will come out readily, it is put on to a perpendicular board like flax, but does not require that quick powerful use of the swinging knife as flax; a light slow brush of the knife downward on the hemp, will separate the wood from the fibre better than a quick motion, and with less waste to the hemp; I would premise that the end before swinging should be cleaned by a coarse heckle. After the hemp is cleaned, two or three handful should be put together, twisted a little and laid a length on the floor, and when a bundle or ball of good size is so piled, it is bound firmly together in three places with handfulls of the same hemp or with rope.

The average yield per acre? The expense of cultivation? The value to the grower when prepared for market? How disposed of? Objections to its culture, &c.? The average yield is from 4 to 30 pounds per acre; the expense of cultivation depends on the quantity of manure, number of ploughings and harrowings in the first place. It is a dry's work to pull a quarter of an acre of good hemp. After pulling, the carting and retting will depend very much on the situation of the pond, whether it be near or distant; as to dressing, I believe a man can break and cleanse 50 pounds of good hemp in a day. The price of hemp in market varies like other productions, though good water-retted American hemp I consider equal to good Russian, yet I believe it does not usually sell quite so high—the price ranges from 10 to 15 cents per pound. I should think that in your section of country much of the hemp that might be raised there would find a home market, to be manufactured into cordage for various uses. I know of no objections to its cultivation; it leaves the soil in a fit

*Perhaps this is a little too early, the weather should cool when it is taken out of the water to prevent fermenting.

in state for any following crop; it fills the ground so completely that no weeds of any kind will grow with it. The amount of vegetation taken from the soil will make it an exhausting crop of course, but the quantity of manure previously put on to the ground reduces the crop, will keep it in a productive state the next. I believe I have noticed all your enquiries, but I fear not much to your benefit, at least I could have been glad to have done it more to my satisfaction.

Letter II.—From Henry Clay.

Washington, 4th March, 1842.

DEAR SIR—My engagements of a public nature are such that I cannot answer one letter in 20 I receive, and I must reply very briefly to yours on the mode of cultivating Hemp. I once wrote an essay on the subject, of which I regret that I have copy to send you. It was published in some agricultural periodical published at Cincinnati.

The best soil for Hemp is a rich vegetable mould, a clay substratum, either fresh, or which has long in pasture. Any stable or ordinary manure pad, if it is necessary to use any, which depends in the degree of the fertility of the soil. Hemp needs very little, and I have known it cultivated successive years in the same field without any manure of the crop.

The ground should be prepared exactly as you would make the best preparation for wheat. A bushel and a peck of seed, or, if the land is uncommodious, a bushel and half, to the acre, should be sowed, at least from the first to the 23th of May. All plants, male and female, are gathered, by pulling cutting close to the ground by a cutting knife resembling a reap hook, but shorter. The plants intended to produce seed are sowed by themselves in rows, and cultivated with the plough and hoe, so as to keep them clean.

The Crop Hemp is pulled or cut (for there is not much difference between the two methods, although after cutting) about the 20th or 25th of August; the proper time is indicated by the Hemp leaves being a little yellow, and the farina escaping when stalks are agitated. When cut or pulled, the stalks are suffered to remain on the ground a few days if they are cured, and if a rain falls on them so late the better, as it will render the separation of leaves from the stalk easier. After being cured, hemp is tied up with a hemp stalk in small bundles, convenient to handle, and shocked in the field. The best farmers, in a week or two afterwards, stack them on the field, throwing the tops inside and the outside.

Stacks in November or in December the stalks are beaten, and the Hemp spread down on the field, or in a shed, to ret. The length of time it should remain depends upon whether the season is wet or dry, but it is not less than seven or eight weeks, and may longer. It is spread as you would spread flax regularly, and avoiding its being tangled. You cannot tell whether it is sufficiently retted or not but by turning up a handful and ascertaining if the lint will separate easily. When sufficiently thus retted it is taken up, and again shocked, and broken out, in the month of February, March, April, &c., as convenient, by a large hand brake. I ask my hands \$0 per day, and allow them a cent per lb. for every yard beyond that. I have known, in some instances as much as 250 pounds per day broken out. As a handful is broken out, the spikes, that is the little pieces of the stalk which adhere to the lint, are fully beaten off, so as to make it clean, and the lint is laid away, and at night tied up in a bale or press, and carried to the Hemp house. All attempts to substitute horse, water or steam power to the hand

brake, and there have been many, have hitherto failed.

The above method is what we call dew retting. I have never tried water retting. That is effected by immersing the hemp stalks in bundles, in water, and keeping them under with weights. September is the best period, and standing better than running water. The length of time may be a few days or more, according to the temperature of the water. You judge, as in the other mode, when it is sufficiently retted.

The Hemp intended to produce seed is suffered to remain in the ground until the first light frost, is then cut, and after a few days the seed are threshed out.

I regret that I have not time to enlarge on this subject. I am respectfully

Your obt^d serv't,

H. CLAY.

MR HENRY COLMAN.

CORRESPONDENCE.

Extract of a letter from C. N. Bement, Albany, of the 21st February.

"I forwarded, a few days since, a communication for your paper, detailing some experiments which we have tried, to make good butter in the winter, which I hope may be of some consequence to the dairywomen and interesting to your readers. We are so thoroughly convinced of the utility of the process, not only in the quality but in the quantity of the butter, that we have procured a supply of water pans for our use, with hot water in winter and cold water in summer. We claim nothing new or original in the matter; but if we can induce the farmers to try it, we shall think we have done some good to the cause. I am certain those who try it will thank me for the information. If I can add an unit to the sum of human subsistence and comfort, I shall consider myself well paid for my trouble, (not pleasure) in communicating it. I will not make any rash promises, but you may be troubled with some more results of experiments which I have made, or shall make hereafter, if my life is spared."

We most certainly hope and desire that our friend Bement's life may be spared, for agriculture has not in the country a more ardent friend to its improvement. His zeal, while it is associated with great exactness of observation, must essentially contribute to this good object. We cannot wish, in the terms of the Spanish proverb, that he may live a thousand years, for that would be much longer than many of his friends would like to remain without seeing him; but may he live till all his agricultural experiments are completed, and as much longer as he himself desires.

Extract of a letter from John Caldwell, at Salisbury Mills, Orange Co., N. Y., dated February 25th, 1842.—On the subject of the Manufacture of Silk.

Mr. Caldwell is an intelligent and attached friend to the agricultural interests of the country; is President of the Orange Co. Agricultural Society of that county; and delivered a very sensible speech at their annual meeting, which we should be glad to transfer to our columns in full, if our limits allowed of it.

We have little hopes of the Government's extending its protection to the industry of the country in a form in which we think the interests of the country demand. At present, it might be well enough to leave the introduction of foreign raw silk free; but we think it should not long remain so, but the production of raw silk should be encouraged by a duty, which should amount almost to a prohibition. We believe that the production of raw silk is of much more importance to the agricultural interest than the manufacture of silk; and that under a judicious law of import, the manufacture would soon grow up, and as rapidly as could be desired, when the raw material

came to be produced as abundantly among us as in three years from this time it might be. Under the operation of a liberal bounty, Massachusetts has within a year increased her production of cocoons from less than three thousand lbs. a year, to more than 27,000 lbs.; and this, as is ascertained, without the bounty, at a net profit of more than two dollars per lb. on the silk. These are most encouraging facts, especially to the small farmers and those who feel the want of profitable employment in their own families, and feel how closely connected with domestic comfort and good morals is the encouragement of what is called household industry.

The silk culture is a subject in which we take the deepest interest, and we beg our friends in all parts of the country, to let us hear from them whenever they have facts to communicate.

"As no doubt you take an interest in the raising of silk and its manufacture, I beg to inform you that Mr. George W. Murray has established an extensive factory, propelled by water power, at Paterson, in New Jersey, for the purpose of manufacturing from the raw material, sewing silk; which he enters he may extend to that of weaving. It has been about one year in operation, and its success is equal to his most sanguine expectations. His dyeing establishment is in very superior style, and turns out sewing silk of beautiful and standing colors, put up in half or quarter pound packets. In the present state of preparation he can only send out 50 pounds on a week's notice, put up as may be required, being daily called on to supply the manufacturers who make fringe, coach lace, &c. This is a kind of silk totally different from sewings. He offers to purchase American silk, or to manufacture it into sewings for the proprietor at two dollars per pound for blacks, blues, drabs and light dyes,—for the higher colours, such as scarlets, crimsons, purple and plum colors, three to three and a half dollars per pound. His works will turn out shortly, independent of the coach makers' supply, 260 pounds per week; and a few days since, he received from Connecticut a quantity of American raw silk to be manufactured into sewings, and to be put up in skeins and on spools. Silk for weaving is made in tram and organdie, but it is not possible to succeed in that branch in this country, so long as there is any duty on raw silk; whereas this material is charged with the same duty as the foreign silks of all descriptions, putting, by this policy, the foreign manufacturer on an equal footing, and all the advantages of cheap labor, with the domestic manufacturer. It is to be hoped, however, that this condition of things will be modified under the contemplated regulation of the tariff. For sometime to come, the entire produce of the raw material in the United States would not produce of raw silk, a thousandth part of the demand. As it may be an object to the growers in your parts to get this information through your valuable publication, you can if you think proper, make it public. In this country we hope to have many specimens of the industry of our people exhibited at our next fair in this branch, and I trust in all others that may and must contribute to our welfare, we shall not be found wanting. I did hope that at our Albany meeting there would have been some expression of our feelings favorable to a protective tariff, and was very much disappointed at the apathy on that subject.

Do not impute to me interested motives in writing as I do about a protective tariff, further than it is an interest every citizen should feel for the well being of his country. I am not, nor do I expect to be, concerned in any manufacture whatever."

Nothing is high because it is high in rank; and nothing is low because it is low in life.—*Dickens's Speech at Hartford.*

Good Temper or Elegant Specimens of Broken Crochery.

"We strike the New Genesee Farmer from our exchange list, the editors having forgotten their promise to send their paper to those who, like us, have published their prospectus. There is a trickiness about it a man-a-vire that the agricultural press should be ashamed of."

There's for you! from the BURLINGTON GAZETTE, printed in Burlington New Jersey, and edited below all question by the President of the New Jersey Peace Society. Unfortunate nights as we are! we failed to see his elegant sheet, until some kind young man presented the paragraph to our utter consternation. But we hasten to make amends. We would by no means lose a sheet so replete with the spice of good humor; and since he has seen fit to send us so unceremoniously to the dogs, we do not presume to ask any longer an exchange all-one-side; but beg him to put us down as subscribers, and promise to pay in the first bill of the United States Bank of Pennsylvania, that comes into our possession.

The next is from the BRITISH AMERICAN SCALVATOR, published at Toronto; and this, another steamboat Caroline affair, threatens the peace of the two countries. It is strange that men living under a petticoat government can be so treacherous and belligerent. We shall certainly tell the Queen, when we see her.

"Desirous of doing all that we could to make our paper interesting, we lately applied, through a friend residing at Rochester, to the Proprietors of the Genesee Farmer, which has been so largely and liberally supported by our own farmers, for the privilege of using their cuts when applied to the subjects in our columns. They of course have many which they could, without inconvenience, send us; but we felt disappointed when we were informed our journal was looked upon as a rival, and that consequently we had no reason to expect any favors from such a quarter."

Now why could not our neighbor, when he stated the case, have given the words and not his version of our answer to his application. Had our neighbor been unfortunate, had he been poor, had he been so situated that he could not procure cuts for himself, we certainly should not have cut him. But the well executed engravings of this present number show that there was no such want. Why should he desire to shine in borrowed plumes when his own feathers are so brilliant? We should be glad to learn upon what principle of morals any man is bound to relinquish to his next-door neighbor in the same trade, any honest advantages which perchance he may have from his industry or enterprise or more liberal expenditures, which some advantages his neighbor may have upon the same terms.

We recollect a student in college sending to his neighbor to borrow his bellows. "The very proper answer was, 'come and use them at my fire all day if you please.' This system is carried to perfection in Michigan. There a woman sent a child to her neighbor's with this civil request, "Mamma wants to borrow your baby because her breast is sore." Now we advise our neighbor at Toronto to move at once over the line, and try in Michigan if he cannot find a cure for his broken temper. We mean nothing unkind we assure him.

To other Papers and Editors.—We are happy to exchange our humble sheet as far as lies in our power, with other editors and papers, and must take our chance of sometimes making an advantageous and sometimes a profitless exchange; not profitless, however, for we shall always be gainers by a friendly intercourse. If in any instance our paper fails to go where it is desired, we beg to be notified, as in no case shall such miscarriage or omission be attributable to any intentional neglect.

THE SEASON.—The plough was under full way on Ontonaga Co in one place on the 11th March

Industry and Economy.

Here is a second letter from Zelia, "mixing the useful with the agreeable." She discusses some of the causes of our public embarrassments and troubles like a politician. We fear, however, she does not do her own sex full justice. We admit that many women have brought ruin upon their families by extravagance in dress, furniture, and entertainments; but we believe this has been done in most cases, because they have been kept by their husbands ignorant of their true condition, and the husbands have been disposed to encourage, oftentimes, this extravagance for the sake of the reputation of wealth or for conceding their own bankrupt condition. It must be said likewise, to the credit of the women, that in general no persons behave better than most of them under the reverses of fortune; and their sense of justice is much more seldom impaired or destroyed than that of men. The advice of Zelia cannot, however, be amiss. We should be glad to enlarge upon it, but shall leave it to her skillful pen.

MR. COLMAN—

Encouraged by the favorable notice you gave the few remarks I forwarded to you last month, I send you the following observations on *Female Economy*, a subject in my opinion, not unworthy of attention in these trying times. There is a French proverb which runs thus: "Women can do everything, because they rule those who command everything." I am not, nor would I advise any one else to be, so vain as to believe this to its full extent, but that such and similar ideas have become proverbial, proves that women possess a powerful influence in society; and we may add, in no country does that influence prevail to a greater extent than in our own. As all rational beings are responsible for the influence they possess, to society and to a higher authority, it may be well to consider how we have exercised it; whether to meliorate the condition of society by promoting temperance in all things, industry, and economy, with their natural consequences, virtue, health, happiness and independence; or whether its general tendency has been to embarrass and impoverish, to promote and encourage extravagance, folly and idleness with all their consequences.

These are important considerations for women of every age, class and condition, at all times, but especially now; and there are no means so effectual to bring them before the public as through yours and similar journals, the public advocates of industry and economy. I believe it is generally admitted that the extravagance which characterizes our age, the enormous expenditures of time and money on *mere trifles*, is the predominant cause of those embarrassments that press with such deadly weight on this country at present; nor need the remark be limited to this country. It is applicable to others, but *our own country* must be the first object of our consideration. No particular class is exempt from the charge. All have lived beyond their means, beyond the limits of common sense and prudence, particularly in our republican land, where it should be the aim of all to secure and maintain their personal independence as well as the independence of their country. Indeed these are inseparable. Neither can be maintained without true economy. No person or people who consume more than they produce, can long escape being enslaved some way or other; nor will the millions, who are now trodden down by ill-used power, ever attain to freedom, so long as they waste their scanty means in imitating the extravagance of those whom fortune, fate, or other powers have placed above them. Economy, public and private, must be the watchword of all who aim at true happiness and independence. Legislation, to be beneficial, must be dispensed on these principles; but the certain remedy, without which all else will be of no avail, must be found in the reformed habits of the people. It does not require much sagacity to perceive this.

What I wish particularly to speak of now, is, the women have done much, both by precept and example in bringing our affairs to their present depressed condition. At the advice and solicitation of wives and daughters, how many husbands and fathers have been induced to assume a rank far above their means, to indulge in those fashionable follies and vanities that have brought such wreck and ruin upon the land! How many splendid entertainments have been given, elegant and costly furniture, carriages, dresses, jewels, &c. &c. purchased by those whose real income would not be justice have afforded any of them, merely to gratify female vanity and love of false grandeur! Such having been the case, it now becomes us, one and all, when our airy castles have vanished into thin air, to make amends by an opposite course of conduct. Instead of endeavoring to rival each other in the costliness and splendor of our dress, furniture and finery, we must endeavor to excel in the prudent management of our domestic affairs. We must consult carefully our means before soliciting our fathers' husbands to buy this, that or the other thing.

Living beyond our means is an unlikely method to gain respect or admiration, and a sure one to bring us to poverty and discontent. *Simplicity* is more esteemed by sensible people, those only whose esteem is desirable, than show or gaudiness. Bright and clean furniture, such as comfort and convenience demand, is better evidence of good taste, good judgment, and good housekeeping, than that which is elegant and expensive; a few well cooked dishes are better and more creditable than a *very great variety*, and thus it throughout the whole range of domestic management. We must attend more to the useful and less to the ornamental. We must devote but a very small portion of our time to the making of head-wraps, net work and such like, while other more important duties are neglected. We should spend few of our mornings afternoons riding or walking in search of health, exercise, while the flower garden, with its thousand charms, craves our spare hour, and offers in return health and the purest and sweetest of human enjoyments. In fine, we should remember that we are a accountable beings, accountable for the time, the talent and the influence which God has kindly given us. Our hours and days should not be permitted to pass unprofitably away, while so much embarrassment prevails and the means of living are so scantily enjoyed by many of our fellow beings. Not a day nor hour scarcely pass a, but affords us an opportunity extending a charitable hand, if we could afford it, a why then should we be so foolish, so irrational, as spend so much as we have done on mere baubles, comparatively? I am not desirous of curtailing the pleasures of life, or hoarding up riches for their own sake; but would recommend such true economy as will promote permanent and rational happiness and enable us to do good where the opportunity presents itself. For any other purpose, the acquisition of wealth is scarcely worth a thought.

This subject, I doubt not, will be deemed by so quite inappropriate for the female pen; but I only regret that I cannot bestow more talent on it. It is well deserving of female attention as an elegant poem or a romantic story. It is now time to treat of the alities of life, stern though they be. I hope the subject will find many and able advocates.

Yours, &c.

ZELIA

P. S. I am much gratified to find a "kindred spirit" such as W. B. in your columns. I hope he will continue to ply his talented pen and give us instructions in gardening now when welcome spring is at hand. I hope I may soon have the pleasure of finding many such spirits in your columns. I am sorry that name did not seem to you appropriate, but you know "Rose" by any other name would smell as sweet."

Marks on Seeds and Seedsmen—Sowing Seeds, Causes of Failure, &c.

The production of living plants from small grains seed dropped in the earth, is one of the most wonderful and beautiful operations of Nature. When examined by the light of Science, it is found to be acted by the combined agency of earth, air, moisture, and heat; and to ensure success, it is necessary that these four elements be combined in due but different proportions, according to the nature and habits of the different kinds of seeds. Hence arises the difficulty of causing some kinds to vegetate; and the certainty which gardeners generally feel respecting many of their crops until they see the young plants near. Hence, also, arise most of the complaints which are made to seedsmen, and the censures which are unjustly cast upon them by inexperienced cultivators.

In order to explain this subject, and with a view to banish the evil, the Proprietor of the Rochester Seed Store has annexed the testimony of several highly respectable and successful cultivators in the country, of some accounts of their methods of preparing and sowing several of the most important kinds of seeds that are liable to fail with careless management. The Editor of the Albany Cultivator, speaking of this general subject, says:—

Seeds often fail to grow; and the seedsmen are often faulted, for vending bad seeds, when the cause of their not growing is owing to the gardener or planter. To induce germination, moisture, atmospheric air, and a certain temperature, are indispensable; and it is also requisite that light be excluded from the seed, until the nutriment of the soil is exhausted, or until the root can draw nourishment from the soil. The first effect of the air, heat, and moisture upon the seed is, to change its properties—to convert its starch into sugar—into a sort of milky pulp, the proper food of the embryo unit. At this stage the seed becomes dry, its vitality is believed to be destroyed; but if these elements are permitted to exert their influence, the contents of the seed swell by degrees, and the first unit of the future root having formed, breaks through the shell in a downward direction, and at the same time the first point of the future stem comes forth in an upward direction. The influence of the air, heat, and moisture are as indispensable to the growth of the plant, as they are the germination of the seed.

Now it often happens, that when seeds are planted in fresh stirred ground, or when the soil is moist, they undergo the incipient progress of germination, and the earth not being pressed upon them, and dry weather ensuing, the moisture is absorbed, and the seeds perish. Too much moisture is also often destructive to the vital principle of seeds; and others again are buried too deep to be vivified by solar and atmospheric influence.—The first object in planting, therefore, should be to cover the seed just so far under the surface, and so cover it with earth, as shall barely secure to it a constant supply of moisture. There are many kinds, as of the carrot, parsnip, orchard grass, &c., which if not previously steeped, or the soil well pulverized and pressed upon them, fail to grow for want of moisture. Hence, in sowing orchard grass, is found prudent to spread it upon a floor and sprinkle it with water, before it is sown, and to pass roller over the ground after the seed is sown; and rice, in light garden mould, it is advisable to press with the hoe or spade, the earth upon all the seeds after they are sown.

On Sowing Flower Seeds.

DAVID THOMAS, an experienced and very successful Florist remarks:—*N. G. Far. Vol. 1, p. 56.*

For large seeds like the Bean or the Pea, a large soil is well adapted, as they can force their way to the surface from any moderate depth; but all seeds require different treatment; and we put it down as a safe rule, the finer the seed, the deeper should be the soil.

How does Nature, exemplifying Supreme Wisdom, sow her most delicate seeds? She scatters them on the shady ground, trusting to the rain or the frost to cover them, (of course slightly,) and they germinate before the sun has acquired power

enough to scorch them. The dust-like seeds of the Orchis and Cypripedium sometimes grow in beds of damp moss.

Common garden loam, whether clayey or sandy, is much improved by a dressing of vegetable earth from the woods, well mixed before planting. If prepared in the preceding autumn, and pulverized by the frost, all the better.

Such a soil is favorable to seeds of almost any kind, but *essential* to the finer and more delicate sowing. The preparation of the soil alone, however, is not enough. Fine seeds may be sown in it covered more than from one eighth to half an inch deep; and their short roots may be parched if exposed to the sun except in morning and evening. To a *fine soil*, therefore, we must add the protection of *shade*, and in time of drought, a regular supply of *moisture*. If the seeds are sown in an open border, a sprinkling of water in the evenings is best, but carefully abstain from applying so much as will bake the ground."

On Preparing and Sowing Onion Seed.

W. RICHES—*(N. G. Farner, Vol. 2, Page 38.)* says,

"First, soak the seeds in water from six to twenty-four hours—some seeds being slower to admit moisture than others, is the difference in the time required. After soaking, drain off the water, and mix the seeds with a sufficient quantity of earth to absorb the moisture remaining on the seeds; stir them often that they may vegetate evenly, and keep them in a moderate degree of warmth and moisture until they are sprouted, when they are ready to put into the ground. If the weather should be unfavorable, put the seeds in a cool place, which will check their growth."

It was left in that situation until the time of sowing. In April, as soon as the soil was sufficiently dry, the sowing was commenced, and the second day at night the sowing was finished, with seed prepared as before stated. In one week the onions were up, rows were soon visible, nearly twenty rods, and no weeds yet appeared. The operation of stirring the soil with rakes and hoes was then commenced, and the weeds were not suffered to grow during the summer. (It is a mistaken notion that it is not time to hoe a garden until it is green with weeds.) The first of September the onions were harvested, and the product was over two thousand bushels of fine onions from two and a half acres."

On Sowing Mangel Wurtzel Seed.

J. RUPATERKES, (N. G. Farner, vol. 1, p. 149.)

"I prepared half an acre of land for Mangel Wurtzel, and obtained the seed from your agent at Canandaigua. After soaking the seed one day, I commenced sowing; but rain came on, and the soil being rather clayey, it was a whole week before I could sow the remainder. The seed was soaked all this time, and supposing it was spoiled or injured, I sowed it thicker than usual, and had not enough to finish the ground. Accordingly I sent to the same place and got more seed, and sowed the remainder without any soaking; so that part of my ground was sown with seed soaked one day, another part one week, and a third part not at all."

Now for the result:—The part soaked one week, came up first, and much too thickly—the part soaked one day, came up slowly and very thinly; while the part not soaked, did not come up at all. Thus showing conclusively, the necessity of thoroughly soaking these seeds and the little danger there is to be apprehended from soaking too long. I am confident that inattention to this subject, is the most frequent cause of the failure of the Mangel Wurtzel and Sugar Beet seeds."

WILLIAM GARRETT, (N. G. Far. vol. 1, p. 20) says, "Much complaint is sometimes made of Mangel Wurtzel and Sugar Beet seed failing to grow. These seeds are not quite as sure of vegetation as some kinds; still, if rightly prepared, and sown when the ground is in good condition, before the weather becomes too dry, they will very seldom fail. The seed should be soaked in soft water, standing in a warm place, *for three or four days* before sowing. The shell of the seed is very hard, and requires a long time soaking for it to become softened so that the germ can burst it open. I have sometimes known it fail after being soaked, owing to late sowing and dry weather."

Planting too deeply.—In vol. 1, p. 97, W. R. Smith states that he "planted half an acre of Mangel Wurtzel with two pounds of seed from the Rochester Seed Store. In a few days some scattering plants made their appearance. Well, nearly two weeks after I was surprised to find a fair number of plants just peeping through, and from their weak and thin appearance, evidently wearied

with their journey to the surface, which they never could have reached, if the soil had not been light."

Another correspondent (p. 121) says "I purchased in the spring, at the Rochester Seed Store, a small quantity of mangel wurtzel seed. Some of them I planted myself, and the ground being dry, I put them in about three inches deep, being resolved they should grow. Another portion of them I left for my hired man to plant, who, I ascertained, put them in still deeper. The first came to rather thinly, although abundance of seed was used; and the second scarcely grew at all. As some of my neighbors had been equally unsuccessful, the conclusion necessarily followed that the seeds, if not the vendors, were no better than they should be."

Having some seed still on hand, and a little more vacant ground, after a rain I concluded to plant the remainder; but working rather in despair than in hope, I buried them only an inch deep, dropping them by the line without making any furrow. The result was they came up as thickly as could be expected from the best of seed with the best of culture. I concluded it must be rather a difficult business to pursue, where one's honesty was thus established merely by accident; and that before condemning others, we should be careful that we ourselves had done our part for meriting success."

Parsnip, Carrot, Celery and Parsley Seeds are all slow to vegetate, and, if sown late and dry weather descends, they will not often come up. These seeds should be sown early, in fine soil, rolled or pressed down and kept moist. Mr. Geo. Sheffer of Wheatland, raises large quantities of carrots for feeding. He sows the seed 48 hours, then rolls it in plaster, and when sown covers it from one half to three quarters of an inch deep.—(N. G. Far. vol. 2, p. 181.)

Cucumber, Melon and Squash Seeds, seldom lose their vitality by age or otherwise, but when sown they often fail to grow, owing to the ground being cold or wet. These, and some other seeds, will invariably rot if sown too early—before the ground is sufficiently warm. Lima Beans and Sweet Corn often fail from the same cause.

Egg Plant Seed will not vegetate in the open ground—it requires a good hot bed.

Locust Seed must be thoroughly scalded, by pouring on boiling hot water and letting it soak 24 hours.

The Love of Flowers.

"Who does not love a flower?"

Its hues are taken from the light

Which summer's suns fling pure and bright

In scattered and prismatic hues,

That smile and shine in drooping dews,

Its fragrance from the sweetest air,—

Its form from all that's light and fair,—

Who does not love a flower?"

"Flowers, of all created things, are the most innocent and simple, and most superbly complex—play things for childhood and ornaments for the grave. Flowers, beloved by the wandering idiot; and studied by the deep thinking man of science! Flowers, that of all perishing things are the most perishing; yet, of all earthly things are the most heavenly! Flowers, that unceasingly expand to heaven their grateful, and to man their cheerful looks—promoters of human joy, soothers of human sorrow; fit emblems of the victor's triumphs, of the young bride's blushes—welcome to crowded halls, and graceful upon solitary graves! Flowers are, in the volume of nature, what the expression, "God is love," is in the volume of revelation."

"The taste for flowers, every where increasing among us, is an omen of good. Let us adorn our parlors, doorways, yards and roadides with trees, shrubs, and flowers. How delightful they appear to the passer by. How favorable we think of the person whose yard and garden is decorated with shrubs and flowers. When we view a dwelling, the doors and windows of which are adorned with flowers, we associate the smiles within with all that is neat, gentle, pure, charming, lovely and refined. Saw you ever a coarse, ill bred, awkward family, where a taste for flowers was displayed? We grow not."

MR. COLMAN—

A goodly portion of your readers are like myself, yet the tenants of primitive log cabins, of which perhaps, coming as you do from one of the oldest states, you are not aware. We are looking forward to the day, however, which shall see us comfortably settled in snug convenient houses, and as the busy note of preparation is already sounded by some of my brother farmers, I have thought perhaps, that a plan of a cheap and convenient farm house might be acceptable; and if your opinion coincides therewith, you are at liberty to serve it up to your readers. It will be observed from the plan above, that there are no fireplaces in this house. Stoves, both for parlor and kitchen, have now come into such general use among farmers, and cooking stoves are now brought to such perfection, that fire-places have become in a manner unnecessary. The chimneys are built upon the chamber floor, and in preparing the frame work of the floor, the part upon which the chimneys rest should have extra firmness, so that it may not settle with their weight. The stove pipes from the lower rooms pass through the chamber floor, and thence by an elbow into the chimneys. Should a fire-place be wanted in the kitchen, one may be constructed with some additional expense; or, which would be preferable, a small room might be finished in the end of the wood-house, adjoining the kitchen door, with a fire-place and even in it. The cost of this house finished in a plain, neat, substantial manner, built of wood, would be, in the county of Wyoming, N. Y., about \$700.

It is a gratifying fact, and one which every observing traveller will notice, that much improvement has been made the last few years, in the construction of

farm houses; the neat, snug, convenient cottage taking the place of the overgrown meeting house style, which has so generally prevailed. Still great errors are often made by farmers in building, and perhaps not the least, is too great an expenditure upon a dwelling house, while the other buildings of the farm, and indeed the improvement and cultivation of the soil are neglected. An instance came under my observation last summer. In passing through Cayuga county, a splendid brick edifice met my eye in the distance, and the thought struck me, that the owner having brought up his soil to the highest pitch of cultivation, and having his barns and out buildings extensive and convenient, and his fields all secured by ample, permanent and handsome fences, had appropriated six or eight thousand dollars, for the want of other use for the money, upon a dwelling house. But upon arriving in front of the elegant mansion, I was sadly disappointed. Bad taste, disorder, and slovenliness filled up the picture; barns and out houses miserably arranged and dilapidated; crooked and rickety rail fences on the road side in a state of advanced decay; and last though not least, an extensive and thrifty crop of Canada thistles upon either side of the road, promising soon to occupy the ground to the exclusion of every thing else.

In the midst of all, behold the splendid monument of the folly of the man who would allow so many thousands to be swallowed up in that stately pile of brick and mortar, instead of applying it to the improvement and cultivation of his soil; in the latter case yielding him a rich return, in the former, remaining totally dormant and unproductive.

J. HORSEFIELD.

Castile, N. Y., Feb. 1852.

Remarks on the above.

We give above the plan of our correspondent, not that we deem it the best which has been or can be contrived, but because it is certainly well contrived, and embraces many conveniences for the extent of land which it covers. The height of posts should be 11 instead of 12 feet, and thus making the lower story 10 feet, it would give four upright feet in the chamber. We protest against bed rooms not larger than 9 by 7 feet. They are inconvenient and unhealthy; and liable to many objections in case of sickness. A bed room should never be less than 12 by 12 feet. By widening the house and lengthening it a few feet, and by adding to the height, which may be done without increasing the extent of the roof, the house would be rendered much more convenient; and the expense not greatly increased. We would by no means give up the plan of a chimney in the kitchen, which, if necessarily closed in winter for the purpose of using a stove, should by all means be open in summer for the purpose of ventilation, when the cooking stove should be transferred to a shed, or to a temporary out-building, if no other convenient place offered.

We are of opinion, likewise, that one window, perhaps as large as one and a half of those described on the plan, or it may be larger, would be more economical and handsomer than two, as put down. About matters of taste, however, there is no occasion for dispute.

The plan, furnished by our correspondent, we are glad to publish on another account, as all such clever plans, if not exactly what any one wants, suggest valuable hints and arrangements to be worked up by other minds according to their convenience.

A plan of building has recently come under our notice, which promises to be economical, substantial, and comfortable. We will describe it. The window frames and door frames are to be first made. The underpinning or cellar wall is then carried up for the reception of the sills, which are to be laid. Strips of boards, in the rough, of an inch in thickness and about 1 or 5 inches in width, are then laid one on the other, flatwise, and nailed through and through, taking care to break joints and to cross or lap at the corners. In

this way the wall is carried up the desired height to receive the plates, upon which the garret floor and rafters for the roof rests. The boards, which are used in this case, may be of any quality, common hemlock or spruce, which should be sawed accordingly, will answer equally well as the best of pine. The wall being thus carried up, is prepared to receive a coat of lim plaster on the outside, which should be sanded or graded; and on the inside it may be plastered directly upon the wall without lathing, and whitewashed. That the surface may be suitable for the plastering both inside and out, the boards composing the wall should not be laid exactly even, but alternately projecting or receding in a slight degree, by which means the mortar will adhere strongly. Such houses are perfectly secure against vermin in the walls; they are substantial and as strong against the wind as any frame house there are no crevices in the walls to admit the air; and they are soon put up, and built at a small expense. Our remarks in this case apply to wooden houses. C. building with stone and brick we may speak at a more convenient time. We agree with our correspondent entirely as to the folly of wasting a large sum of money in a large and expensive house, before the farm itself is put into the highest and most productive condition. Yet no error is more common. It may be laid down as a well-nigh established truth, that no man knows how to build who has not built.

Winter Buttery.

Every person at all familiar with making butter in winter, is aware of the difficulty attending it. Butter made at this season, is generally deficient in color and flavor, is white, crumbly, and not considered fit for the table. This arises partly from the cows being kept, as they generally are at this season of the year exclusively upon dry food, and partly from not rigidly managing the milk.

In the statements of Mr. Merrifield, who took the 3d premium for butter at the late meeting of the State Agricultural Society, he says—"In winter, or milk stands 12 hours, is then removed to the stove and scalded over a slow fire to near boiling heat; the pans removed to the cellar to cool; the cream only churned; the butter placed in the coolest part of the house, will keep good for any length of time." His butter was much admired for its color and flavor, but he thought the scalding process rather tedious and troublesome.

In the 7th edition of "Moubray on Poultry, &c." I found the following, which struck me favorably, as I was determined to profit by the hints.

"A peculiar process of extracting cream from milk by which a superior richness is produced in the cream has long been known in Devonshire: this produces the dairies of that country, being well known to every one by the name of 'clotted' or 'clouted cream.' There is no peculiarity in the milk from which this fluid is extracted, it has been frequently a matter of surprise that the process has not been adopted in other parts of the kingdom. A four sided vessel is formed of zinc plates, 12 inches long, 8 inches wide, and inches deep, with a false bottom at one half the depth. The only communication with the lower compartment, is by the lip, through which it may be filled emptied. Having first placed at the bottom of the upper compartment a plate of perforated zinc, the cream of which is equal to that of the false bottom, a gale of milk is forced (immediately when drawn from the cow) into it, and must remain there at rest for twelve hours; an equal quantity of boiling water must be poured into the lower compartment through the lip; it is then permitted to stand twelve hours more (that is twenty four hours altogether,) when the cream will be found perfect and of such consistency that the whole may be lifted off by the finger as a thumb. It is, however, more effectually removed

ally raising the perforated plate of zinc from the bottom by the ringed handles, by which means the bottom of the cream is lifted off in a sheet, without mixing any part of it with the milk below. With this apparatus I have instituted a series of experiments, and as a mean of twelve successive ones, I obtained the following results:—4 gallons of milk, heated as above, produced, in twenty-four hours, 43 quarts of clotted cream, which after churning only fifteen minutes, gave 40 oz. of butter—4 gallons of milk heated in the common mode, in earthenware pans, and standing forty-eight hours, produced 41 pints of cream, which, after churning ninety minutes, gave 40 oz. of butter. The increase in the quantity of cream, therefore, is $12\frac{1}{2}$ per cent., and of butter 11 per cent."

From the above hint I caused a pan to be made five inches high and very flaring, and another made five inches high and just large enough to receive the cream pan, and then carefully soldered together at the rim. Two tubes were affixed, one an one inch in diameter, the other quite small, as it is only intended to let off the air when the hot water is introduced on the opposite side through the large tube. The annexed cut will perhaps convey a better idea of the pan. The dotted lines showing the inside pan.

The following are the results of my experiments:

EXPERIMENT 1. Strained 11 lbs. of milk, fresh from the cow, into the pan, and after standing twenty-four hours, put four quarts of boiling water into the outer pan and secured the apertures with corks. After six hours after, the cream was carefully taken being very thick and tough, and of a fine yellowish color. Twelve hours after it was churned with spoon, which occupied seven minutes, and produced 5 oz. of butter.

EXPERIMENT 2. The same quantity of milk was put into the same pan, and after standing twelve hours, four quarts of boiling water were introduced, and suffered to stand twenty-four hours, when it was skimmed and immediately churned, which took eleven minutes to convert into butter—produce 6 oz.

EXPERIMENT 3. The same quantity of milk, fresh from the cow, was put into the pan as before, and suffered to stand twelve hours, four quarts of boiling water were then put into the outer pan, and after standing twelve hours it was carefully skimmed, and twelve hours afterwards was converted into butter in five minutes—produce 7 oz.

We now put the three parcels together, and after being well worked, they weighed, with a common set of steelyards, 1½ lbs., being a fraction less than four quarts of milk to produce one pound of butter; to be remarked, however, that the milk was taken from a two-year old heifer, and the difference in the quantity of the butter when separate, or put together may be accounted for by the difficulty of weighing small a quantity with the steelyards.

EXPERIMENT 4. Strained 11 lbs. of milk, fresh from the cow, into a pan of the same size as above, after standing thirty-six hours, it was carefully skimmed and the same process as before adopted to convert it into butter. After diligently working at it one hour and on half, it "was no go," or in dairy language, it would not "come." We then tried to get it by adding a small quantity of cold water; then of warm water, but it was of no use. It was then left for twelve hours, when it was tried again, and after working at it for half an hour, gave up in disgust; "come" it would not, and so we concluded to let "go"—to the cook.

Two other experiments were tried, on the "high heat" or hot water principle, which resulted about the same as Nos. 2 and 3, except the time consumed

in churning—one being four minutes and the other seven minutes; the difference was caused, probably, by the temperature of the weather.

From the above experiments, I am well satisfied of the utility and advantage of the process, and have no doubt but a great saving may be made and good butter produced, even in the coldest weather. I would suggest an improvement in the pans and a saving in expense; besides considerable trouble in washing and drying the pans. Let the inner pan be made smaller in diameter at the top, so as to strike the other about one inch from the top, and fit tight, so that the steam will not escape—after putting in the hot water set the pan containing the milk into the other. By this means, they being separate, can be washed and dried without difficulty.

Butter is one of the staple productions of our state, and every hint that serves to improve its quality or increase its quantity must be useful. There are various methods of making butter; and there is certainly a vast difference in its quality. One cause of this difference may be in the herbage or food upon which the cows are fed, the breed of the cows, or the season; but most generally in the management. Every one thinks their own method the best, and feel too wise to learn, and sneer at the idea of Philosophy or Science having any sort of connexion in this humble branch of domestic industry.

A writer in a former volume of the N. E. Farmer says, in regard to the color and flavor of butter, "to correct both these evils, take four yellow carrots, of about 1½ inches diameter, to cream enough to make ten pounds of butter, and after washing them, grate and cover them with new milk, and after they have stood ten minutes squeeze them through a cloth into the cream, and the effect has been to make the butter to come quicker, and give it the color and sweetness of May butter. Mrs. B., who sits at my elbow, suggests, as an improvement on the above, to give the carrots to the cows in sufficient quantities, and readily believes that carrots used in that form, will impart a fine color to butter and add even a rich flavor—that substance and not the coloring matter must be required to give much flavor.

C. N. BEMENT.

Three Hills Farm, Feb. 1842.

Remarks on the above.

We are happy to publish the above communication from our friend Bement. We like it the better because it comes from one who knows what good butter is; and is written with a certain lady at his elbow, who sent to Boston the last year a parcel of butter which was among the best seen in that market.

The pans which he describes we have seen in use in one of the best dairies in Berkshire county, where they are much approved. His experiments are valuable, though we should like a little more exactness in weighing. The process of heating the milk, as may be seen by an article in our last from a fair correspondent, is not new; but the best contrivance for scalding it that we have seen is, where a vessel was used, large enough to contain six pans, and about eight inches deep, so that they might be set in three or four inches of water, and this vessel with a copper foot or shoe to it, with which the water communicated, and which was put into the side of a stove over the fire, so that the water in this way might be easily boiled. This vessel had a wooden cover and thus the milk was heated in this water; and as soon as the bubbles rose upon it or the fixed air began to escape, the milk was removed into the dairy room to throw up the cream. This was less trouble, we think, than using the double pans, which Mr. Bement describes.

We have seen as fine and delicious butter made in winter as in summer, but not upon clear hay. There is reason to think that the color of butter depends somewhat upon the cow, somewhat upon the place

where it is kept, and much more upon the feed of the animals. We agree entirely with Mrs. B., with Mr. Bement's leave, that the best mode of coloring the butter with carrots, is to give the cows the carrots and let them mix the dye.

We know that with enough of these and some Indian meal and clover hay, yellow butter and butter of a fine flavor may be made as well in winter as in summer. We shall take up this subject hereafter when we have more room.

Mr. Bement was foiled in one case in attempting to make his butter come where the milk had not been heated. We have now on our table a letter from a subscriber begging us to give her a reason for just such an occurrence. We recollect many such a weary churning in days gone by. We might look wide and say very leniently in the case that it was undoubtedly owing to the temperature in which the milk or cream was placed; but this explains nothing. Here we think chemistry has a real and useful work to perform. But with present information, the only reason we can give why the cream in such case will not come is that of the woman, if it is not an impeachment of the sex to suppose such a case, who would neither be coaxed nor driven. "I want; why? I can't I want." We don't know every thing, though we begin to think we ought to, from some inquiries that have recently been put to us.

House Plants.

Are an article in whose culture, to our shame be it said, we have never had much experience. Yet we do admire them—vastly and sincerely love them and wherever we see their cultivation, we must in spite of ourselves and the little prejudices which sometimes intrude themselves upon our feelings, entertain kind and charitable feelings towards the dwellers. What cheerfulness they present in the gloom of winter, when the world without lies sorrowing under the influence of decay and the elements are heaved in commotion by the rocking storm? Then they lift their bright smiling heads and remind us of summers past, and awaken strong hopes and bright expectations of smiling suns and flowery scenes in summers to come. For so much pleasure as they afford, they require but little attention, and this little time, if not employed in their behalf might be much worse spent. We know of young ladies who spin their full two runs of street yarn every day in investigating the affairs of the neighborhood, merely to furnish the petty wool of scandal, who might be much more agreeably employed with a favorite geranium or rose, (if no new novel was at hand) and less to the annoyance of community. And young men, too, who by this harmless employment a few minutes each day, would render service to the world which ought to be appreciated.

The propagation and culture of house plants is very simple and easy in the process. Though each variety may require a somewhat different soil to succeed well; yet as a general rule, a mixture of pond-mud, sand and common soil, about one third of each, answers a good purpose. We have found mould taken from the woods and from around roots of trees blown down, where the soil is considerably mingled with sand, to be very useful. Some, require almost a pure sand, and in putting out slips this is probably valuable, as it is loose, allowing the feeble roots to strike freely, and lets off the superfluous water which is often injurious and fatal to the young plant.

In selecting slips for putting out, the beauty of the plant will be more effectually secured by taking those of upright growth. Such rise higher and form better heads, while if lateral ones are cho-

EXPLANATION.—Mr. Colman has of necessity been sent during the last half of the past month, for the purpose of closing some business in Massachusetts and removing his family to Rochester. He is expected to return about the 15th inst.

For the New Genesee Farmer.

The Mild Winter and Early Spring.

It has been observed that mild winters have occurred regular distances of 26 years, as follows:—1686, 1712, 1738, 1764, 1790, 1816, and 1842. The mildness of last winter was a subject of constant remark, particularly among the farmers, who observe the peculiarities of the seasons with more interest, perhaps, than any other class of citizens. This led me to compare the monthly temperature of the corresponding months of the last three winters, viz: 1810, 41 and 42.

Dec. 1840, monthly mean, 5.37 degrees.

" 1841, " " 20.66 "

Jan. 1840, " " 19.45 "

" 1841, " " 97.91 "

" 1842, " " 29.41 "

Feb. 1840, " " 32.47 "

" 1841, " " 24.27 "

" 1842, " " 31.03 "

The mean temperature of the winter 1841, 25.85 deg.

" " " " 1842, 30.40 "

The mercury in the Thermometer did not fall to zero last winter; the lowest, Jan. 24, being 5 degrees below zero.

Farmers, I think, will recollect how exceedingly cold the month of March was, 1841,—mercury five degrees below zero, the 17th; ten degrees lower than any time last winter.

March, 1841, monthly mean 28.55 degrees.

" 1842, " " 39.77 "

A difference of about 11 degrees.

It will be observed that March, 1841, was colder than either January or February, 1842.

First ploughing, February 12th.

Spring birds made their appearance much earlier this spring than last. Robins, blue-birds and pigeons, were seen March 3d. Frogs were heard, and the earth-worm came above the surface at this date.

Bugs and flies were seen in the woods February 3d; also, a grasshopper and mosquitoes in the city.

Vegetation is also much earlier than last spring. Violets were in blossom Feb. 5th in the open garden; Lilacs and shrubbery leaving. One soft maple in blossom March 4th, and covered with honey bees, and many in blossom March 24th, also common elm; apricot in blossom, April 10th; peach and cowslip (caltha) 15th; plum, 19th; shepherds-purse, 20th; English cherry, 22d; hard maple, shad bush, (Aronia. Botry-

apium) and strawberry, 23d; currants, 24th.

Last year cherry and peach began to blossom May 21st; thus you observe that they are more than a month earlier this spring; and so of vegetation generally. Wheat and grass look very fine.

April 23d was a very warm day; the mercury in the Thermometer stood at 82 degrees in the shade, and 81 in the sun.

NOTE.—There was but little snow here last winter, but frequent rains, and some very heavy thunder showers; the first Jan. 20th.

The quantity of rain and melted snow during the winter ending Feb. 1842, 5.78 inches; do, 1841, 4.27 inches.

The harbor at the mouth of the Genesee river was clear of ice February 1st, and the 6th the river was very high, from the melting of the snow on the southern hills. Last year it was uncommonly high March 31st.

" corresponding half, 1841, 31.90 "

Agricultural Facts, for 1842.

The Monroe County Agricultural Society will hold their annual Cattle Show and Fair at Rochester, on Thursday and Friday, the 13th and 14th of October next. (The list of premiums, by-laws, &c., will be printed and circulated as soon as they can be prepared.)

The Ontario County Agricultural Society have advertised that their Fair and Cattle Show will be held at Canandaigua, Wednesday and Thursday, October 12th and 13th, but it is proposed to alter the time one

day and hold it on Tuesday and Wednesday, 11th and 12th, so as not to interfere with the time of the Monroe Society. (The list of premiums, by laws, &c., have been printed and circulated throughout the county.)

The Livingston County Agricultural Society will hold their next Fair and Cattle Show at Genesee, on Tuesday, the 4th of October. (Premium lists have been circulated.)

The Ontario County and Seneca County Societies have both advertised to hold their Fairs on Tuesday and Wednesday, October 11th and 12th, the same time as the Ontario county. It is greatly to be regretted that there should not be some mutual understanding among the Societies in the vicinity of each other, so that the days of their shows and fairs should not be the same. It would gratify many of the members to visit each others shows. In this way substantial good might be done and much pleasure given; emulation would become more spirited; the pleasant intercourse of farmers would be extended, and useful information imparted and received. This ought to be arranged at the meeting of the State Society by the different delegates. It is not too late now to arrange it by mutual consultation. There is still plenty of time to circulate notices. (We intend in our next to give a full list of the days and places of as many Societies as will send us the requisite information.) As far as it can be done, delegates should be sent from one society to another, to attend the Fairs, and thus strengthen and extend the bonds of good fellowship. "Our interests are one and indivisible."

Cauliflower.

Our success in the culture of Cauliflowers until the last year, has been equal to our desires, and they are not very small when so good an article is sought for, and the failure of '41 we attribute mainly to *worthless and defective seed*, as from the first paper we sowed, only a half a dozen vegetated, and from the second none at all, which gave us rather a limited supply of plants. The seeds of both papers, one of which was labelled at an establishment in Chautauque county, were very shrivelled and imperfect, having the appearance of being gathered prematurely, as we have no doubt they were. Now this is *too bad*. It is a down right outrage upon the public to offer even under hand and seal such seeds in market. The state of public mind and such, with regard to the culture of rare and delicious plants, that if some sort of success does not attend their exertions, their efforts will cease, and our seed establishments will go where the cauliflower seed we bought last year ought to have gone, instead of coming to market—to the bugs.

When good seed is obtained they are raised as easy as cabbages, will flourish on the same kind of soils and require the same culture. They are superior in taste and healthfulness to any of the cabbage family.

W. B.

W. R. Smith of Macedon, Wayne Co., had a plough in full motion by the 4th of March, and one team had, by the 23d, ploughed about fifteen acres

AGRICULTURAL ADDRESS.

We publish with pleasure the following valuable address, delivered February 1st, before the Cayuga County Agricultural Society at Auburn, N. Y., by David Thomas of Aurora. Mr. Thomas is well known to the readers of the New Genesee Farmer as one of its most frequent and instructive correspondents, and for two years a co-editor of this journal. We cannot say we assent to several of the positions taken in this address; first, because several of them relate to matters which are at present obscure and unsettled; and second, because some of them are not confirmed by our own observation and experience. But we do not like the address the less for this reason. We cannot be supposed, because we publish them, to endorse the opinions of our correspondents or of others. This we beg to say, once for all, is never to be assumed or inferred; but we do as little hold ourselves infallible, and are always desirous in all cases "to hear the other side." Mr. Thomas thinks for himself and has a mind of his own. We like him all the better for this. We should be sorry to have every body agree with us; or ourselves to agree with every body else. This would be very dull work; and put an effectual stop to all inquiry, and consequently to all intellectual progress. This would make the waters of life stagnant and putrid. They might be radiant and beautiful on the surface; but all their freshness and spirit would be gone, and who would wish to drink of them. We value books, discourses, sermons, addresses, &c., for two reasons; first, when they convey some useful knowledge or information; second, when by their original and independent thoughts, whether we acquiesce in their truth or not, they set our minds in vigorous operation. But how few are of this character, or any thing more than the stereotyped repetition of matters, which every school boy has by rote. When an independent thinker, therefore, utters his convictions, be they ever so distant from our own, we always listen with pleasure; but when one of your parrots gets up, who never spread his wings nor ever learnt to say anything but what he heard other people say, and looks as grave as an owl, and then shakes his head as though there were some thing in it, and with wonderful parade of learning informs us, for example, "that the light of the moon being reflected is not quite so intense as that of the sun, and that water is a fluid and the tendency of fluids is to run down hill, and so on," we confess we are sorry to say that that whether at home, or, if we must tell all, at church either, we are so overpowered with admiration or something else, that we have great difficulty in keeping awake.

Cayuga Co. Agricultural Society--Address.

Geologists inform us that soils were chiefly derived from the wear and tear—the disintegration and decomposition of solid rocks. In some tracts of country, the soil is nearly identical with the rock that immediately underlays it, or partakes largely of its nature; but such occurrences are rare in this country. So extremely active was the deluge that swept over and rounded our highest hills, that many a square league of stony atrata was entirely buried by materials that drifted from other parts of the country, and which have no resemblance to the rocks they cover.

Favorably for the southern parts of our county, that deluge came from the north, sweeping over a limestone region, and depositing in its course over our barren state, the rich collection it had made. And here let us stop to consider: if that flood had come in an opposite direction, bringing along the unproductive detritus of the mountains, instead of our fertile fields, and flocks and herds, we might have witnessed nothing more inviting than scrub oak plains, and a few wandering deer.

Like other floods, however, its deposits were irregular, as its velocity was increased or retarded—as it whirled into eddies, or rushed onward in its course. Pure clay indeed, can scarcely be found in this formation; but all the varieties of loam, whether clayey, sandy, or gravelly, occur; and some deep beds of both

sand and gravel, are so pure as not to discolor the water into which they are thrown.

Such instances, however, are rare; and the grinding and mixing of so many substances by that deluge, have been eminently beneficial to our farms. No soil is fertile, says Humphrey Davy, "that contains as much as 19 parts out of 20, of any one material or constituent. On the contrary, soils that contain mixtures of many things, are generally very fertile,—provided that clay, lime, and sand, form a large share of the mass. When you see, therefore, old mortar, the sweepings of the smith shop, or leached ashes thrown into the highway, you may safely conclude that the owner is greatly in want of instruction. These are excellent manures, and permanent in their effects."

Perhaps some would ask, why are different things necessary to constitute a fertile soil? Allow me to answer in the language of Dr. Jackson's Geological Report on Rhode Island: "Chemical science arranges all bodies as electro-positive, or electro-negative. The electro-positive are always the alkaline or basic substances, while the acids are always electro-negative when brought in contact with matters of the positive class. If a soil is wholly positive or negative in its nature, it fails to be fertile; and when one power greatly predominates over the other, it is not in its most favored condition. Silica is regarded as an acid, and alumina, lime, magnesia, iron, and the alkalies, are its opposites."

According to this view, the soil may be considered as a vast galvanic battery. "It is rendered nearly certain," says an eminent writer, "that manures act by the salts they contain, acting when brought in contact with the earths in producing galvanic currents," and of course stimulating the plants in their growth. On this subject, however, I give no opinion of my own, because I can comprehend much more clearly, the neutralizing effects of acids and alkalies, and the absorbent power of any soil of the different materials. This point may be dated our practice quite as well as the farmer; and indeed there seems to be nothing discordant between them.

It is not many years since the existence of acid soils was deemed overlooked. The talented editor of the Farmer's Register in Virginia, was the first to point out the error or oversight; and the subject is now better understood. He furnished no evidence in support of the presence of uncombined acid; but the circumstantial evidence was very strong and pointed; and in my judgment he fairly made out his case. Since the publication of his "Essay on Catechu Manures," other writers of great respectability, have either adopted his views, or furnished additional and convincing proofs of their correctness.

The question may occur, why is not an acid soil as fertile as any other? It is more fertile than any other for such plants as the Red Sorrel; but not for the plants which are the chief objects of the farmer's culture. These generally require a neutral soil—that is, one in which lime under some form or other, occurs in considerable quantity.

Although clear, according to Dr. Jackson's classification, is arranged as an alkaline earth, yet as such, it is so feeble that when united with silica or sand alone, the mass becomes acid, and unfit for our usual crops. On such lands, Indian corn assumes a yellow sickly aspect, even when it is not injured by stagnant water. And what is the cure? Apply lime copiously, and then, says an accurate observer, "the corn soon takes immediately a deep, healthy color, and before there is any perceptible difference in size. The crop will produce from fifty to one hundred per cent. more the first year, before its supply of food can have possibly been increased." And why? Because the poison, which has paralyzed it, was destroyed.

It is well known that when magnesia occurs among quick-lime, it is often injurious to the land. Such a mixture is called *hot lime*, from its burning alkaline quality; the magnesia not combining so speedily as lime does, with carbonic acid, which would render it mild. Besides, the lime, having a stronger attraction for that acid, will either be served first, or take the place of the magnesia, till it has got enough.

When the lime has been long in the heap, I have seen spots of earth, where the lime has been three or four years, in which the *crucian larvæ*—as free from vegetation as the floor for two or three years, although the ground had been carefully scraped over when the heap was removed.

Yet such is the stuff to which the south eastern part of Pennsylvania owes much of its fertility. Formerly, when I lent a hand to that process, it was considered that 30 or 40 bushels to the acre were as much as the land could bear without injury. It was found,

however that rich land would bear more than 10 loads; and in process of time they discovered that 10 bushels to the acre might be safely and profitably applied to pastures or meadows. The lime was stacked in large heaps; and then from a cart or wagon on a calm day, it was scattered with a shovel evenly over the grass. It fell among the decaying leaves which in warm weather yield carbonic acid, and it became cold without injuring the crop.

Some years ago, I published an account of this simple method, believing it superior to that of any other country, and you may judge of my surprise to see it stated in a work of high authority, bearing the date of 1840, that magnesian limestone is unfit for the purposes of agriculture!

Lime, however, possesses other properties besides that of neutralizing acids. One of the most remarkable is the power to absorb putrescent manures; and to hold the fertilizing essence till it is wanted by the crop, through every vicissitude of the seasons, and through indefinite periods of time. There it is, locked up; and nothing at common temperatures but the energy of a growing plant, can unlock it."

Lime has heretofore been styled the basis of a good husbandry. It sours up the manure that is not immediately wanted, for future use—a kind of *bank all*. When the supplies from the barn yard are spread and ploughed into a soil that is nearly destitute of lime the growing crop catches a part of its virtue, but a very large part escapes, and very little will be left for the benefit of those that succeed. I had been used to such soils until I removed to my present farm and was in an agreeably surprised to see how much more durable were the effects of stable manure. My fields were limed by the deluge.

Unwholesome vapors and villainous smells, also absorbed by lime; and some places once remarkable for insalubrity, have been changed in their character by liming or marling the fields around them. Nuisances are converted into manures. A striking illustration of this principle is contained in the following account from the Essay on Calcareous Manures.

The carcass of a cow, killed by accident late in the spring was laid on the ground, and covered by about 25 bushels of broken shells mixed with 45 bushels of corn chiefly asleep. After the rains had settled the heap, it was only six inches thick over the highest part of the carcass. The process of putrefaction was so slow, that several weeks passed before it was over, nor was it ever so violent as to throw off any effluvia that the encephalic crust did not intercept in its ascent, so that no offensive smell was ever perceived. October the carcass was heaped up and applied to the cultivation of an acre of wheat; and the effect produced far exceeded that of the encephalic manure, which was applied at the same time on the surrounding land.

The same valuable work contains a caution to the farmer which may save him from dangerous error. "He is not to suppose that calcareous earth can be rich a soil by direct means. It destroys the worst of productiveness, [acidity] and uses to the great advantage the fertilizing powers of other manures, but of itself it gives no fertility to soils, nor furnishes the least food to growing plants." In other words, it is the strong box for the treasure, but not the treasure itself.

Lime also possesses the property of making soils closer and firmer, and clayey soils lighter. It is a mean between two extremes.

I was conversing several years ago, with a farmer from a sandstone district, who expressed some surprise that 40 bushels of wheat could be raised to the acre. "I don't believe," said he, "that our land could be made rich enough to produce such a crop without lodge." I am entirely of the same opinion unless lime be employed. Stable manure is too slow in acting—the stem grows too rapidly—it is succulent and weak. Whether the lime by combining with silica assists in stiffening the stalk, or not, we may be certain at least, that it yields nourishment as the plants need it; and that every part will be healthy and properly developed.

Professor Emmons says in one of his Geological Reports, that the most fertile soil formed artificially by the mixture of different earths, yielded on analysis 37 per cent. of carbonate of lime. As it is known

*The following extract from Liebig's Organic Chemistry is cited as a parallel case:

"An abnormal production of certain component parts of plants, presupposes a power and capability (of a similitude) to which the most powerful chemical action cannot be compared. The best idea of it may be formed by considering that it surpasses the power of the strongest galvanic battery with which we are not able to separate the oxygen from carbonic acid." p. 154.

ever, that time in some soils, soon ceases to be a manure," it is probable that the real quantity of lime even greater than what was indicated by the analysis. I have seen soils of remarkable fertility, that finally contained a very large proportion of lime; and there is no danger of having too much when it is properly applied.

When the soil is low in plants supplied with water? After a shower, the soil may be wet enough for a time; when the sun and wind dry the surface, the moisture rises up from below by capillary attraction, as the water allows rise up through the wick of a candle to supply the deficiency above. It is from this circumstance that our crops over deep beds of sand suffer in dry weather than where the subsoil is hard and impermeable, showing the benefit of deep and thorough ploughing. In either case, however, as the soil begins to fail, and the soil grows drier, its deep parts absorb moisture from the air; and the plants are constantly nourished by this invisible fountain.

But the different constituent parts of the soil, and the different degrees of energy. Of the carbonaceous, siliceous is the weakest, and the aluminous the strongest, while lime holds an intermediate position. One of these, however, would do by itself. We want sand, because no soil consisting entirely of impalpable matters is fertile; and we want it to keep the soil loose, so that the air can enter its pores, and go up the water which it holds as vapor. Without this assistance, stiff clay or aluminous earth would absorb but little moisture from the atmosphere, because cakes, and shuts out the air. Lime is also a valuable auxiliary in rendering the soil more absorbent, independent of its other indispensable qualities.

But the soil, however it may be tempered and conditioned, can never be absorbent in a high degree than culture. Some crops indeed require more of it in quality than others. Thus Indian corn requires more than wheat; and wheat more than the grasses of the meadow. But vegetable and animal matters are more absorbent than the earths; and culture only in properly introduce them into the soil. Even when, therefore, frequent stirring is necessary to keep the ground loose and the pores open, for the free admission of the air and the easy passage of the roots.

Our coats sometimes become spotted with mud. We apply the brush, but the bristles pass over without effecting its removal. What is the reason? The soil which was suspended in the water, forms a glaze on the coat. It is just so with the interior of a soil which has been long unsifted. The clay forms a crust round the inside of all the little cavities, preventing the free circulation of air, and the introduction of fresh vapor. The fertilizing principles are excluded.

The celebrated Tull, observing the extraordinary effects of high culture, concluded that plants fed on yellow earth, and DUHAINE adopted the same notion. Their philosophy was coarse, but their practice was wise. If we were to follow their example, making plenty of fine earth for the plants—not to feed on, but to drink from, our crops might be greatly increased. One of the chief errors of our husbandry is to cultivate too much land, because it is only half done. Half the quantity with double the work on it, and double crops would be found more profitable.

I have long believed, however, that no part of the system required reformation more than our management of manures. Manure has been called the wealth of the farmer. When it is taken out in the spring, it is commonly scattered over the ground in large mounds; the plough comes along and covers them, or, at least, the wheels may be. It is covered, they intercept the ascent of the moisture from the soil, especially in dry seasons. If not covered, they are washing on the ground—of very little value. Indeed some excellent farmers have satisfied themselves that strawy manure is unprofitable for summer crops.

I am far from holding that opinion, however. The error consists in not applying it to the soil in the best manner. In the spring of 1840, I had no ground for field beet, but a small lot where corn had grown for two years in succession. It was unfit for such a crop without manure; and I had only fresh manure from the stable, which has long been considered most unfavorable to the beet. My necessity, however, prevailed against opinion; and I took the responsibility. From each line where the beets were to grow, two furrows were turned so as to leave a wide deep furrow. Into this the manure was thrown from the

wagon, each fork full touching the one just behind it, till the row was completed. It was well covered by turning two furrows together over it, which held it down while the harrow was passing four times in succession, breaking, pulverizing, and mixing it intimately with the soil. Again two furrows were turned together over the row, and the harrow passed twice more in all, six times. By this process the ground was reduced to a fine tilth; and if there were any better beets in the county, I did not see them.

To me, it was a most instructive experiment. I have often seen manure applied to corn fields, but never in any case where it was so completely incorporated with fine earth. Even in the driest part of that season, the ground was always moist and mellow.

I am satisfied that we have been too saving of our harrows. Thirty years ago, there was a method of ploughing in this country called "cut and cover." It was ploughing, not to the shares, but the *hatters*—the furrow slice covering the space where a furrow ought to have been. I am apprehensive that our ideas of ploughing have declined in the same school. When grain is sown, is it not the prevailing opinion that it is sown too deep when the seed is covered? I had a narrow land harrowed sixteen times in one day, and was satisfied that the labor was well applied.

For beets, or corn, or potatoes, what would be the effect of ploughing in a heavy dressing of stable manure, harrowing twice, and repeating the operations of the ploughing and harrowings four times more, adding each time to the depth of the soil? I have not yet performed the experiment, but the nearer I have approached it the finer has been the crop. Thorough culture would seem to require that every little lump should be broken, so that the roots could wander freely in every direction, and that every drop of a summer shower, should be caught and retained for future use. Hard land and thin soils have some resemblance to a dish bottom upwards.

An instrument for pulverizing the soil was invented a few years ago in Virginia, by Thomas B. Gay. It is called the Drag-roller, for it operates just as a roller would that does not turn, but drag. Take a hollow log, six or seven feet long, split it in two, and one half would serve for this instrument. The greater the diameter, the easier it would run; and be less liable to clog by gathering clods before it. Three feet would be better than two, though either would answer. Frame two pieces of sealing iron to it, connecting them in front; and to this fixture the team is to be attached.

Do you believe that clods as big as a man's fist, or as big as his head, are more useful to the crop than stones of the same size? I do not. But if we break them—grind them to dust—and leave them on the land, they would do as much good as other mellow earth of the same bulk. Now in warring against the clods, this instrument is formidable; and most so before they become thoroughly dried. On the same day, therefore, that the plough turns them up, let the drag-roller grind them down; and let me suggest that lumps of barn yard manure would escape not much better.

Stable manure, however, is often saved for the wheat field, and at any time during the summer, either before or after harvest, it is taken out and thrown into heaps, where it lies wasting until seed time. It is then drawn down into large mounds as before mentioned, the plough covering some, while others too big to cover, stick up over the field. If the wheat is harrowed, perhaps some of these pyramids are upset or demolished; but often the harrow serves them as the plough did—gives them a shove and passes on. Now it seems very clear to me that manures applied in this way, is comparatively of little value.

There is another class of farmers who manage things differently. Soon after the warm weather commences in spring, they collect all the manure of the barn yard into large heaps; and work it over, two or three times in the course of the summer, so that the straw may moulder and be more easily mixed with the soil. This advantage—the only one that I can discover, is indeed secured, but at a heavy expense. The best part of the manure passes off to visit their neighbors, or roams at large through the atmosphere, leaving the worst part, though still of some value, for the owners. The praise of industry is theirs, and the reward of working for nothing and finding themselves.

Another set of farmers, more enterprising still, make up all their barn yard manure into compost. This is done by successive layers of manure, rich earth, and lime, together with any refuse stuff, animal or vegetable, that may be at hand—to be turned and mixed several times in the course of the season. Such manure is always valuable; but with a little more knowledge, its value might be much increased.

Let us consider this subject. From a heap of fermenting manure, a vapor continually rises, very different from the exhalation of a pond, as our noses might testify. Perhaps some may think that such thin dust as that would be of no consequence to a plant; but I can assure them it is the best part of the manure. Humphrey Davy filled a three pint vessel with a long neck, from a fermenting heap of stable manure while it was hot, and turned the beak among the roots of some grass. Nothing but vapor left the vessel; yet in less than a week the grass grew with much more luxuriance than the grass in any other part of the garden.*

The value of this vapor is therefore evident; but how shall we save it? In the first place, the fermentation should be very gradual. Make the heap in the shade, or on the north side of a building, and manage it just as you would manage a coal kiln. The more the air is excluded, the slower and better will be the process. Now covering it with earth will have this effect; but vapor will rise even when it ferments slowly, and therefore manure must be free to scatter through the heap, as it is made; but no quicker. In warm weather, should form an outside covering for the whole pile (when manure is not at hand); but it should be carefully prevented from coming in contact with stable manure, or any animal matter. It must not touch them. It spoils them. A layer of earth should be interposed; and then the lime would be highly useful in catching and retaining the fertilizing vapor as it rises.

I believe there is no difference of opinion on this subject among chemists. Humphrey Davy speaks in the plainest language against mixing quick-lime with common dung as injurious; and other eminent men fully accord with the doctrine. On the outside of the heap, however, quick-lime in a few weeks would be carbonated; and after undergoing this change, it might be safely mixed with the compost. A fresh coat may then be applied.

But some farmers may not wish to apply their barn yard manure in the spring, or make it into compost; they may prefer using it after harvest, and yet not have it wasting in the mean time. In that case I would advise that it be thrown inward where it lies thin, just so far that this work conjointly with the work of covering it, shall amount to the least labor. Then cover the whole with straw or earth to protect it from the sun; and cause it to be trodden down by the cattle as far as possible to exclude the air, and prevent fermentation. Some of you may recollect when forking up such matters after harvest, that the straw in spots was bright and unchanged. That was where it was well trodden. All change is attended with loss; but as some change may be expected, strew lime or marl and plaster, gradually over it, to absorb, or arrest the fertilizing vapor.

The effect of plaster (composed of lime and sulphuric acid) has long been a source of wonder; for it was a wonder how one bushel could add more than 20 times its own weight to a crop of clover. Inquiring minds of course have been busy in trying to explain the mystery; but I doubt if all the properties of this manure are understood even at this day. Humphrey Davy was inclined to think that plaster was a necessary part of the woody fibre of some plants, analogous to the bony matter in animal structures. The plant could not do without it, though it wanted but little; and hence so small a quantity had such a powerful effect. "Plants which seem most benefited by its application," says that eminent chemist, "always afford it on analysis."

When this theory was announced some thirty years ago, it was rejected in this country, where the effects of plaster were much better known than in England, and he could have shown that it enters into such plants in any definite proportion, some of the arguments against him might have been refuted. It appears, however, that he never pursued the inquiry with much interest.

Judge Peters of Pennsylvania, had done more than any other person to extend the knowledge of this manure, and to favor its introduction. He had been very diligent and minute in his inquiries; and though not a professed chemist, became satisfied that sulphuric acid was the active ingredient in plaster. He showed from the observations of Beraud, that lands near Catania in Sicily, abounding in volcanic matter, including sulphur, were very fertile; and from an experiment by the same person, that brimstone, pounded, sifted and mixed with ashes, had a surprising

effect on lucerne and clover. Sulphur acid greatly diluted with water, had a similar effect.

As a further confirmation of the effects of sulphur or sulphuric acid, when Chancellor Livingston was travelling in Flanders, he saw the farmers preparing pyrites for manure. The mineral is a combination of sulphur and iron, and when partially burnt is employed in the same manner, and for the same purpose as we use plaster. Dr. Chapman of Pennsylvania, found a similar result from sulphuret of barites.

Last summer, a new work called ORGANIC CHEMISTRY, by Professor Liebig of Germany, was first published in this country; and it has been considered by those best qualified to judge, as constituting a new era in agriculture. It is not my intention, however, to detain you with any of its details, except his explanation of the effects of plaster on growing plants.

Ammonia is an essential part of the food of plants. It abounds in all vegetables, without exception, with the nitrogen that enters into their composition. It is very volatile; but sulphuric acid (dissolved by the plaster) can prevent its flight, and fix it in the soil. This can only be done, however, when the plaster is dissolved. The sulphuric acid then unites with the ammonia, and the carbonic acid of the ammonia unites with the lime.

Such is the purport of Professor Liebig's explanation of this great mystery. If he is correct in ascribing all* the effect of plaster to this new combination, its importance in the economy of our farms, must be evident. All our fields, pastures and meadows, ought to be strewn with it; and in accordance with his suggestion, it ought to be scattered in all our woods, and over all our barn yards. The quantity required is not great; and many experiments may be instituted at a trifling expense.

I ought to say, however, that this theory appears insufficient for explaining all the phenomena, in connection with the use of plaster. Why is its effect on clover so extraordinary, and on what so insignificant? Judge Peters, after using it forty years, and he never found it beneficial on winter grain; and others, after long trials, thought it did little for the natural grasses. All these, however, are powerfully affected by stable manure—by the very ammonia which that manure yields. And what do we observe? Clover of luxuriant growth, and close along side of it, wheat without any indication of benefit received, though both have been plastered alike.

Again—Professor Liebig informs us that every shower of rain, or fall of snow, brings down ammonia to the ground where the plaster ought to arrest it, and the plants that feed on it ought to be more thrifty; but we have much testimony to show that on many fields no trace of such improvement could be discovered. These facts may not be inexplicable; but they appear to me at present, quite sufficient to bring a doubt on.

I am aware that we have statements in regard to the use of plaster, of the most conflicting kinds, so that with some few exceptions what one denies, another affirms; but would this be so if it acts SOLELY in the manner described by Professor Liebig? A simple cause might be expected to produce a uniform effect. For instance: if Hondeette is a simple cause; and as far as I have understood, it operates with uniform effect, whether on clover, wheat or caldages.

On some soils indeed, plaster is uniformly efficient—not the trace of any effect is perceptible. This inertness has been more frequently observed in the tertiary formation near the sea coast; and therefore it was ascribed to the salt vapors. Plaster, however, succeeds well in many places on the coast, and fails in others far beyond the sea breeze, so that the cause seems to reside in the soil, and not in the air.

There are several substances that decompose plaster, besides the carbonate of ammonia. Carbonates of potash and soda have the same power. In the hands of the chemist, plaster and common salt readily change into sulphate of soda, and chloride of lime; and Judge Peters says: "I have seen a bushel of plaster by a handful of salt—it was unfit for either cement or manure." Some of the oxalates also effect its decomposition.

When this happens, the plaster no longer exists; and most of these results are not known to be of much value as manures. Such failures, however, rarely occur on calcareous soils, or on such as contain a due proportion of lime. There plaster generally proves beneficial; and even in England it has succeeded on

such lands. Many years ago, in the south eastern part of Pennsylvania, some farmers thought it would supersede the use of lime; but it gradually lost its effect; regaining it, however, when the land was limed. Wherever plaster proves of no use therefore, TRY LIME. On a small scale, it may be done at a trifling expense; and may lead to the most beneficial results. And remember that plaster must be dissolved before it can do any good. Sometimes there is not rain enough for this purpose in summer, and therefore there is always a risk to sow it late in the spring. Let it be done early.

I have now arrived at my last paragraph. From bogs or deep swamps, manure may be manufactured to a great extent. Three parts of peat and one of stable dung are mixed together and fermented through the summer. It was used in England* many years ago; and has been found in New England, equal to the same bulk of stable manure, and more permanent in its effects.†

For the New Genesee Farmer. Strictures on Mr. Garbutt's Views respecting Roots and Improved Stock.

MR. EDITOR—I was much surprised on perusing Mr. Garbutt's remarks in the January number of the New Genesee Farmer. I did think he would have been the last man that would go against agricultural improvement, and especially root culture and improved stock.

It is admitted by the intelligent cultivators of Great Britain, that the root culture has doubled the products of the soil of that country. There one fourth, and frequently one third, of the arable land is annually sown to turnips or mangel wurtzel, and the advantage of this crop to the cultivators is almost past calculation. The greatest proportion of their beef and mutton is fattened in the winter with these roots, and their stock are wintered on them and straw. Where the farmers of this country to adopt the same improved husbandry, the benefit to them would be equally great. It is true that labor here costs much more than it does there, but that is more than over balanced by the exorbitant rents and heavy taxes which have there to be paid. Were each farmer here to raise 40 or 50 acres of roots annually, (which they could easily do) our country would soon wear a very different aspect. Instead of the poor miserable animals which generally occupy our barnyards in the spring, they would exhibit the fat and thrifty appearance of our stock in October, only much improved in size and beauty, as in England. The greater part of our beef and mutton would be made in winter, and we would not only save our summer's pasture, but our animals would be much better fattened and their flesh of much more value; instead of 2½ cents per pound, it would be worth 8 or 10. There would also be a great saving of ground and labor by wintering the stock with out hay, and the consumption of so many roots in winter would greatly increase the barnyard manure, which is the farmer's gold mine, and thus enable farmers to enrich the soil and double the amount of their grain crop per acre. Such would be the beneficial results of introducing the root culture, and the benefit of introducing the "best and most improved stock" will be of more importance, and if possible of more profit. Let any one look over the sales of these beautiful animals which have been made in this country for four years past, and he must conclude that \$200 per head will be a low calculation for an average price of such animals in future.

I think that the average value of our native cattle which are slaughtered at home or drove to market, will not average over \$25 per head, but say \$30, and what an immense difference in value and profit, is there in favor of the Improved Darhams. And the improved sheep are also well worthy of attention. The 10 or 12 lb. Cotswold fleece is of much more value than the Merino's 3 lb. fleece; and the

35 or 40 lbs. of good mutton per quarter of the former, are certainly of more value than the 10 or 12 of the latter. Were these improvements in husbandry but generally adopted, the products of the soil would be doubled and the wealth of the country increased threefold; and then the hue and cry about hard time and the scarcity of money, would vanish like smoke before the wind.

These facts, Mr. Editor, are self evident to all who are not willfully blind, or stupidly ignorant; therefore persevere in your well doing, extend your valuable paper to every cottage, hamlet, yes, and stately mansion, that all may know what they can do for themselves and their country. And to effect such laudable purposes, I propose that each friend of the New Genesee Farmer pay for three copies annually, to distribute them amongst those of their acquaintances who are not willing to pay for it, and it will soon be in the hands of all.

I remain most sincerely,

A FRIEND OF IMPROVEMENT.

February, 1842.

Corrected Views on Root Crops and Improved Stock.

MR. EDITOR—I am glad to see that you call on your intelligent correspondents to correct my erroneous ideas published in the last number of the Farmer. We are all liable to form wrong conclusions, and frank discussion of them, with liberality and kindness is the only way to arrive at truth; and why should I cultivators of the soil quarrel with each other? We have one general interest, viz., the improvement of the soil, and the increasing of the products of our labor. Petty jealousies or individual strife should never disturb the free interchange of our views.

But, my esteemed friend, I think that you mistook my suggestions. It was far from my intention to insinuate that labor and capital judiciously employed were not rewarded to the American farmer. I think that we, who are lords of the soil, do reap the fruit of our own labor. We are better off than any tenants in the world, independent of the enormous rents and heavy taxes of England.

Nor did I intend to hint that the root crop, to a moderate extent, was not profitable. I know the reverse from experience, and much regret that farmers in general pay so little attention to it.

And I am, also, as warmly in favor as any one, of rearing and maintaining the *most improved* and *best* (but I would rather say most profitable) stock for the country. It was my wish to convey this idea, and I did not do it, you must excuse a ploughman's blunders. There are great differences in countries relative to the profit of certain crops; what suits the one does not always answer for the other, and in introducing any new thing, it is very essential that we should first test its value or advantages on a small scale, so as to prove them thoroughly, before we adopt them as our own. It is yet my notion that there would be no harm in always doing so. This jumping at every new thing as a trout does at a fly, is the bane of agricultural improvements, and prevents us from bringing anything to perfection. They who have the means to give \$10 per bushel for Robin Potatoes, or as many hundreds for a Durham Bull, can do so; but if they should have to pay for the one by raising potatoes at 20 cents per bushel, or the other by beef at 2½ cents per pound, I fear that they will think that they have paid rather too dearly for the whistle, and their ardour for improvement thus receive a severe lamper. That various agricultural productions are better adapted and more profitable to be raised in one country than another, is not denied by any. It would not be very profitable for a Cattaraugus farmer to sow annually 100 acres of winter wheat, nor for us Westerners to stock our dry soils with redtop. If I am

* The evident influence of Gypsum upon the growth of grasses, depends only upon its fixing in the soil, the ammonia of the atmosphere.—Liebig, p. 142.

long in stating that England is better adapted to extensive root culture, and that it is more profitable here than it can be here, I hope that I have done no more in saying so, and that it will not prevent any one from trying a few. That the heavy Dutch roots which arrive soon at maturity when supplied with abundance of succulent food and extraordinary care, are better adapted and more profitable for that country, where such food is abundant, labor cheap, and beef high, than in ours, where all are the reverse, is my humble opinion, and I hope that none of my low farmers will be offended at my saying so. I have often wondered and much regretted that these enterprising and wealthy gentlemen, who have not so much money in introducing these fine, heavy roots, have never taken the trouble to ascertain the exact amount of flesh, or *thirty* that they make for food they consume, and let us know for certainty, how much they are preferable to our native stock. Let any one pass through various parts of Western New York in March and April, and see the number of mangled and half starved cattle which are strutting about the naked fields, or shivering by the side of a fence or empty barn, and he will have reason to think that it would not be much profit, to such farmers at least, to have animals that require more food to better care.

If we feed, and breed, our animals so as to improve them, our native stock would soon become good; and if we do not do so, the best breed in the world will soon degenerate.

Yours most respectfully,
W. GARBUTT.

Wheatland, February, 1822.

We must say that we consider the sentiments addressed above by our good friend, with his qualifications, in the main sound and orthodox; and so far as his feeling any diffidence in sending or we in publishing, let him understand once for all, that we are for the fullest and freest discussion. So far from being offended at another man's honest opinions being thus differ from ours, we should just as soon ink of being offended because his eyes are blue and his black; or because the point of his nose does not open to be placed at the same angle of inclination to the right or the left as our own. Away with such gotry, it is only fit for fools and Inquisitions!

On the other hand, while we think our friend Garbutt is likely to err on the side of too much caution, a friend of Improvement," is a little too buoyant in enthusiasm, and his morning sky is colored mediocrity beyond nature. In their present condition we cannot think of putting two such animals in the same yoke side by side; but with friend Garbutt in the files and a "friend of improvement" forward, we may go along safely and successfully, though in each case there must of necessity be considerable rubbing of sides and of launches, and a great loss of power.

Now with all due respect for our friend Garbutt, we cannot see the advantage or necessity of beginning with the alphabet when we have already learnt to read, nor with a "friend of improvement," that because we have learnt to read, therefore, we know everything, and there is no longer any occasion for books. There is always some danger in going between opposing parties of getting hustled ourselves, but we shall, if we can, get through, no matter if our coat is torn.

The value of raising vegetables for stock and in large quantities is well established in England. Why cannot we avail ourselves of their experience in a question which they have settled; and let stock raising farmers, and wheat growing farmers too, make, as George Shaffer has done, the growing of roots for

stock an indispensable branch of husbandry? The extent to which we pursue it must be settled by a sound discretion, having reference to our wants and to our means, and to the whole of our condition. But the question of their utility, in respect to keeping our stock and the means of enriching our farms, is no longer an open question here any more than in England.

Then again in regard to the introduction of the improved breeds of cattle among us. In England the most extraordinary pains have been taken for more than half a century, the highest skill exerted and the most lavish expenditures incurred in improving their breeds of cattle; and through the liberality or the commercial enterprise, or, if you please, the avarice of many individuals, public spirited or otherwise, we have the advantages of these improvements placed directly within our reach. Now why should we not avail ourselves of them, either by judicious crossing with the best of our breeds, or by adopting the pure stock and making for them such provision as is demanded, in order to maintain their superiority? Such exertions would very much benefit our husbandry and undoubtedly give us an ample profit. At the same time the expectations held out by "a friend of improvement," that 200 dollars per head for our cattle will in such case be a *true* calculation, and instead of getting 2½ cents per pound for our mutton we shall be sure of 8 or 10 cents, is not a calculation that we should think safe to encourage, certainly not in the present dilapidated and fluctuating condition of our currency, when no man can tell for his life, what a dollar is worth. Prices are of all matters in political economy, the most difficult subject of calculation, combining, as they necessarily must, in order to any safe reckoning, so many various elements, such as the condition of the currency, the supply of the article, and the demands of the market. With these brief hints, we submit the case between the parties to the court.—[Editor.

Madder.

Our respected correspondent, L. A. L., who desired some information from us on the culture of madder, we are compelled to refer to the subjoined notice which appeared in the *Genesee Farmer* in 1837, vol. 7, no. 39., which perhaps will be as full as he desires; if not, let him do us the favor to say in what particulars he desires further information, and we will meet his wishes. We have delayed replying to his inquiry, because we hoped we should find some individual personally acquainted with its cultivation and management. That has not been our good fortune, and we have never seen the plant growing. We should infer from the statements given, that the crop might be cultivated to much advantage, if we have only patience enough to wait for the harvest; but as to present prices of the article we know very little, and what price it is likely to bear here hence, who is gifted with the power of divining?

"Madder, or *Rubia tinctorum*, is one of a large family of plants, and for its valuable qualities in coloring has become an important article of cultivation in several countries, particularly Holland, where the province of Friesland is almost wholly devoted to its production. In Radcliff's *Flemish Husbandry*, the following condensed rules are given for its culture: The soil a rich sandy loam of from two to three feet in depth, as the roots must have room to penetrate;—the land laid up in ridges in autumn if to be planted in the spring, and left bare till the middle of March, or in April, on ridges if the ground is wet, if not, on a level, in rows 18 inches apart, and the plants 12 inches distant in the rows;—as much root as practicable should be taken with the slips to be planted, and from six to eight bushels will be required for an acre, though this of course must depend mainly on the distance adopted by the planter;—plant nothing in the intervals, but as the tops shoot up bend them occasionally to the ground and partially cover with earth;—when the tops fall off in autumn, earth the rows as a protection against frost, and in the spring hoe the intervals thoroughly;—the slips of the second year are the best to plant, and should be taken off in the spring when about an inch above the surface;—three years are required for the roots to arrive at perfection, when

they are dug by deep trenching, the roots quickly and carefully dried to prevent discoloration or molding, and then ground and packed for use.

Madder roots are long and creeping, about as large as a quill, red within and without, and a single plant will, in a good soil, yield about 40 pounds of fresh roots, which will in drying be reduced about six sevenths. Some have dug the roots in two years, but the roots do not then contain the proper quantity of coloring matter; and if they stand longer than three years more is lost than is gained after that period. All parts of the root contain some coloring matter, but it is in the middle part that the most and the best is found, the mucroscous showing in this part a multitude of shining red particles, constituting the rich dyeing material, thickly dispersed among the fibres. "According to experiments made in England, five pounds of fresh root goes as far as four of the dry one; and it is estimated that seven or eight pounds of fresh roots are reduced to one in drying; hence the great advantage of using green roots where practicable, becomes apparent. They are more extensively used in a fresh state in France than in any other country, and are the recalled *alfazari*." Good madder when ground for the market is of an orange yellow, passing into a brown red, having an acid sweetish taste and a strong smell.

Some improvements in the culture have been made since it was first attempted here, and if the mode of product per acre may be considered as a criterion, our methods have the advantage over those practiced in Europe. Mr. Woodberry of West Winfield, Herkimer Co., in a letter to the Cultivator, says,—"It is now ascertained that the best method of planting madder, is in beds six feet wide, with four rows of plants to a bed, leaving a space between the beds nine feet wide unoccupied; or it may be planted with rows of corn or potatoes the first season. This space is useful for various purposes, as passing with a team to early manner, should it be considered necessary the first and second seasons. The manure should be dropped between the beds, and mixed with a plough before it is used on the beds." By treating the intervals in this way, Mr. Bronson, a cultivator of madder in the same vicinity, on a few acres of land planted with madder, raised upwards of one thousand bushels of potatoes; and handsome crops of corn have been obtained in the same way. The advantage of planting in beds, arises from the greater extent to which the tops may be covered, as each earthing, properly performed, adds materially to the quantity of the roots produced, the top itself to that extent being converted into root, and not to be distinguished in its qualities from them.

The following estimate prepared by Mr. Woodberry, and it does not very materially differ from those furnished by other cultivators, shows at a single glance the expense of cultivation, and the value of the article produced when ready for market.

Seed per acre 8 bush. at \$4.....	\$32.00
Interest on land 4 years at \$100 per acre.....	11.20
Ploughing and harrowing.....	2.50
Dressing first year.....	25.00
" second year.....	7.00
" third year.....	3.00
Digging.....	21.00
Drying, 25 cents per cwt.....	12.50
Grinding do do.....	12.50
Total expense.....	\$111.70

Product if well cultivated, 5000 pounds, average price 20 cts. per pound.....\$1000.00
Deduct.....111.70

Clear profit.....\$888.30

We have heard but one serious objection made to the culture of madder, and that is, the long time required for its cultivation allows great fluctuations to take place in the price; and these which may arise at the time of commencing with the crop, cannot be relied on as those which will prevail when the article is ready for market. When we remember, however, that the demand is steady, and increasing; that the quantity produced is not likely to vary suddenly; and that for a number of years the price has ranged between 17 to 25 cts. for good qualities, we think little apprehension need be entertained of an overstocked market, or heavy sales. Seed at the proper seasons, may, we believe, be obtained of the growers in the region we have mentioned, as well as mills for grinding the roots, and we should be pleased to learn that farmers suitably located, had added to their other sources of profit, that of the culture of madder."

SCIENTIFIC AGRICULTURE.—Letter 24.

Before quitting the subject of Carbon, it is proper to advert to the experiment which is now frequently tried, and which I have recently seen here.

A Hyacinth bulb was placed, early last November, in a tall glass jar with about three inches of good rich earth, and plentifully watered, the mouth of the jar was then closed as well as possible with cork and sealing wax, and this was done so effectually that the moisture did not evaporate; consequently but little if any air could enter, and the original air within the jar, therefore, remained unchanged by admixture with the fresh external air. The Hyacinth grew vigorously, and in the month of February flowered luxuriantly. Now it is clear that the carbon necessary to form four or five large leaves and a full grown spike of flowers could not have been derived from the small quantity of carbonic acid gas contained in the air in the jar, nor even from the bulb alone; hence a large portion must have been obtained from the humus of the mould—the carbon of which, combining partly with the oxygen of the air, but chiefly with the oxygen of the water, formed carbonic acid gas for the use of the plant. This confirms the opinion of Liebig, who states that the principal use of Humus is by its combination with oxygen, to provide an atmosphere of carbonic acid gas for vegetables to convert into carbon during their growth. Although the trial with a bulbous root, which in the bulb contains already considerable provision of material for growth, is not so fair an experiment as it would be with a plant wanting a bulb. Yet I know from experience, that a hyacinth does not contain near sufficient in its bulb to bring its flowers to perfection without any other aid.

The practical value of these considerations on the subject of Carbon is, that Humus being a considerable means of supplying carbonic acid gas to plants, it must be exposed in sufficient quantity to the action of air and water to generate this gas. This is done by cultivation, in other words, by stirring the soil, keeping it in fine tilth, and thus continually exposing to air and water fresh portions of it—for this purpose also, the admixture of a moderate quantity of stones of proper size is useful, they keep the earth more free and open, and increase the surface of the soil where they are in contact with it, so that more humus is exposed and kept in admixture with moisture.

Azote.—It seems to be well ascertained that, whatever quantity of nourishment be offered to a plant and taken up by it, this nourishment cannot be digested, (assimilated as it more properly termed in vegetable life,) unless it be accompanied with a certain proportion of Azote—in other words the plant cannot convert its food into luxuriant growth without the aid of this substance. It follows then, that however rich the soil may be in other nutrient, if azote in abundance be not supplied, this surplus of undigested food taken up by plants will be again thrown off by them in the shape of gum, honey dew, or other excrements, with every indication of disease. This operation has a perfect parallel in animal existences; a certain quantity of azote is necessary for the digestion of their food. As upon the views taken of this substance, azote, depend results of the utmost importance to agriculture; its nature and properties cannot be too well understood, its application and effects cannot receive too much attentive consideration. I may, therefore, at the outset, be permitted to enter into a few scientific details which shall be as brief and as clear as I can make them.

Payen, a French Chemist of high repute, who has devoted much time and study to these enquiries, has shown that azote is requisite in the formation of a substance in plants analogous to fibrin in animals; that this azotated substance is the origin of all the parts of plants, is always present with, and accompanies all their

organs. Azote is therefore, necessary to produce, with other materials, this concrete fibrous substance, as the rudiment of all vegetation. Azote also serves to produce the liquid albumen which all coagulable juices of plants contain, and a substance called caseum, which has often been confounded with this albumen.

Fibrin, Albumen, and Caseum, therefore, exist in plants, and these three azotated substances offer a remarkable similarity in properties with the three non-azotated substances mentioned under the consideration of Carbon—thus,

Fibrin, like woody fibre, is insoluble;

Albumen, like starch, coagulates by heat;

Caseum, like dextrine, is soluble.

A more profound analogy also exists in the simplicity of the combination of their elements, thus, 18 molecules of carbon, 6 molecules of ammonium, and 17 molecules of water, constitute or may constitute by a different arrangement of these molecules, either fibrin, albumen, or caseum; and thus in both cases carbon and water, or ammonium (containing azote) and water, are the only ingredients necessary for the composition of the substances on which we are now treating, and the production of these ingredients is constantly renewed by the circle of reactions of the animal and the vegetable existences as stated in my last letter.

Now it is of much importance to observe closely and separate distinctly in the mind, two operations of nature in the growth of a vegetable, because it will be seen that ample provision must be made for each of these operations. These two important periods are, first, the growth and increase of all parts of a plant, that is stem, leaves &c., until the flowers and fruit appear in their earliest stages, and fecundation and ripening begin; the growth and increase of the first period is then gradually arrested, and a new or the second operation commences. It may, I think, be conclusively shown, that if we were to continue during the summer and the early autumn constantly to apply fresh stimulus in the shape of manure and moisture to a plant, take for instance one of annual duration, we should obtain an immense growth of leaf and stalk, but the fruit would amount to nothing—on the other hand, if we abstain from applying moisture and stimulants to a plant half grown, we should obtain premature but worthless fruit. This fact is well known to gardeners who, by confining the roots in small pots and depriving them of stimulants, force their plants into premature bloom—or it may be observed on hot and poor spots of land, where the same causes are in natural operation. It is, I believe, sufficiently apparent that proper soil with a sufficient supply of carbon and azote, or in plain terms, well manured land, and plenty of water, are the indispensable requisites for the first operation, and equally so, that sunlight and heat are the necessary conditions for the second operation. If the manure on a hill of corn be examined when the fruit is formed, it will be found pretty well exhausted of its powers—they are no longer absolutely requisite, they have played their part, the chief necessities now are sunlight and heat, with a degree of moisture in the atmosphere sufficient to keep the outer coverings or integuments, and particularly those of the seed and seed vessel, in a soft and yielding state, until they become well filled with the materials which this light and heat is converting in other words ripening, from the saccharine and other juices prepared in its first stage of growth.

The phenomena attending this second period are extremely curious. During the first period the vegetable manufactures and stores up an ample supply of saccharine and other juices, containing chiefly carbon and hydrogen, now when a bud is to open, a flower to be fecundated and fruit perfected, heat is required, and is produced precisely by the same method as in animal life, by the consumption, or rather by the combustion

as it ought to be termed, heat being produced, of the carbon and hydrogen in these saccharine juices. The bud root, for instance, previous to flowering, contains a large quantity of saccharine juice, after flowering however, this has all disappeared. If barley or wheat are made to germinate, heat carbonic acid and water are produced, the starch which these grains contain; converted, first, into gum, then into sugar, and the carbon and hydrogen which this contains, are changed by combustion into carbonic acid. Fecundation is a ways accompanied by heat, flowers respire carbonic acid, they therefore consume carbon; this carbon, the sugar cane, for instance, must arise from the sugar accumulated in the stalk, which sugar disappears when flowering and fructification are accomplished. Thus at certain periods in certain organs, a plant, like a animal, becomes an apparatus of combustion—carbon and hydrogen are burnt in it and heat is given out. This view of these phenomena, will sufficiently account for the differences of opinion amongst many of the early observers of vegetable physiology, on the subject of plants respiring carbonic acid, oxygen, &c.

In my next letter, I will endeavor to give some account of the means, both by the common and by artificial manures, of supplying that absolutely necessary substance, azote—and if I am fortunate enough to obtain any insight into the new artificial manure which has produced the effect on wheat I mentioned in a late letter to you and which is now being manufactured for sale in England, I will communicate the information. I suspect, however, that the same manure was under process of manufacture here last year and I am now awaiting the trial of its efficacy. J. E. T.

Indian Corn and Wheat Alternately.
MR. COLEMAN—

I do not send you a description of the manner in which I have raised my corn for a few years past, because I think my crops have been over large, but rather from their uniformity in yield, which is a desirable object for every farmer in all his crops.

For the last five years I have alternated corn and wheat, drawing from my barn-yard in the spring, from thirty-five to forty wagon loads of long manure to the acre, putting it upon wheat stubble, spreading it evenly, and ploughing it under at least eight inches deep then harrowing lengthwise of the furrows, and marking rows three feet apart each way, planting six to eight quarts of seed (Dutton) to the acre, from the 5th to the 20th of May, according to the season. When up, I leave but four stalks in a hill. I tilled with a cultivator, and hoed twice during the summer without hilling, and harvest by cutting up at the ground from the first to the tenth of September, and draw it off and set it up to cure.

The land is then ploughed once and sowed to wheat; one and a half bushels of seed to the acre, and well harrowed in. From the above management, my corn has yielded for the five years, at least sixty bushels to the acre, as ascertained by accurate measure; besides giving about two tons of stalks to the acre, which I calculate to be worth at least three fourths as much as hay.

My soil is a gravelly loam, dry and warm; subsoil differing very little from the surface, except a little more tenacious. One advantage in planting corn on wheat stubble is, that it is not as liable to be injured by worms as when planted on sward land. My wheat that I have sowed after corn, has yielded from twenty to twenty-five bushels to the acre, except the past season, which was quite a failure, owing to the badness of the season.

Genesee Co. March, 1842.

M. N.

Editorial Remarks.—Emulation in Agriculture. We call the above good husbandry. Sixty bushels of Indian corn and twenty-five bushels of wheat are certainly very good crops, but they are only half enough

animal, the kind, quantity and cost of food, to entitle them to the premiums.

TO BREEDERS.

To the breeder of the best Bull, class I, . . . \$10
To the breeder of the best cow, class I, . . . 10
To the breeder of the best Heifer in class I, . . . 10

ON HORSES—Over 4 years old.

For the best Stallion, . . . \$20 For the best breeding mare & colt, . . . 20
For the second best, . . . 12 For the second best, . . . 12
For the third best, . . . 5 For the third best, . . . 5

The butter offered for premiums may be presented in butter tubs, jars or firkins.

The claimant for premiums on butter, must state in writing the time when it was made; the number of cows kept on his farm; his mode of keeping; the treatment of milk cream and milk before churning; the mode of churning, whisking and salting; the method of freeing the butter from the milk; the quantity and kind of salt used; whether salt-petre or any other

substances have been employed; the best time for churning and keeping butter in hot weather; and the best mode of preserving it and through the summer and winter, and in what vessels.

Those who present cheese for the premiums offered, must state in writing the time when it was made; the number of cows kept; whether the cheese is made from one, two or more milkings; whether any addition is made of cream; the quantity and kind of salt used; the quantity of rennet used and the mode of preparing it; the mode of pressure and the treatment of the cheese afterwards.

FIELD CROPS.

Best crop of Wheat, not less than one acre, . . . \$15

The third best, . . . 3
The fourth best, . . . 1

Those who present claims to premiums for farm crops must state in writing the following particulars: The condition of the soil at the commencement of cultivation for the crop; the previous cultivation, product and manure used upon it; the quantity and of manure the present season; the quantity and cost of seed used; the time and manner of sowing, cleaning, and harvesting the crop; the amount of the crop determined by actual measurement; and the expense of cultivation. The land shall be measured by some sworn surveyor, and the claimant of the premium, with two other persons who assisted in measuring, shall certify under oath as to the quantity produced from the piece of land mentioned in the certificate of the surveyor.

MAPLE SUGAR—50 lbs.

The best specimen, . . . \$10 The third best, . . . 5
The second best, . . . 10 The fourth best, . . . 3
Applicants for the premiums on maple sugar will be required to furnish a statement of the manner of making and clarifying the sugar.

DISCRETIONARY PREMIUMS

will be awarded for such implements and products, not enumerated above, as shall be deemed worthy of notice and encouragement.

HORTICULTURAL PRODUCTS, &c.

The list of premiums on horticultural and household products will be published next month.

PREMIUMS FOR ESSAYS.

I. The best paper treatise on Agricultural Chemistry \$10
II. The best essay on the Rotation of Crops, best suited to the soils of this State, . . . 20
III. The best essay on the General Management of the Farm, . . . 20
IV. The best essay on the introduction of New Agricultural Products, . . . 20
V. The best essay on the Management and Application of Manures, . . . 20

TO ARTISTS.

I. To the painter of the best specimens of Original Portraits of Domestic Animals—A Gold Medal.
II. To the engraver of the best specimens of Portraits of Domestic Animals on wood—A Gold Medal.

PUBLIC SALE OF STOCK.

On Friday, Sept. 30, there will be a public sale of stock; gentlemen wishing to dispose of their stock are requested to enter them with the Recording Secretary previous to the 15th Sept., that the catalogue may be prepared in season.

RULES AND REGULATIONS.

Applicants for premiums are requested to pay particular attention to the notes attached to the premiums on Dairy Cows, Fat Cattle and Fat Sheep, Butter and Cheese, Field Crops, Maple Sugar, and to the following regulations.

All persons who intend to exhibit cattle, horses, sheep or swine, should give notice to LUTHER TRUCKER, Recording Secretary, Albany, previous to the 15th September, in order that the necessary accom-

modations may be made for them, and all animals must be on the ground by 9 o'clock of the 28th.

All persons intending to compete for the premiums on plows, must send their plows to the Recording Secretary, Albany, previous to the 1st of August next, that the committee may have opportunity to test them thoroughly, and at such times and places as they may think best, and be prepared to report at the Fair.

All other agricultural implements must be sent as above, on or before the 25th of September, that the committee may have an opportunity to test them in the day before the exhibition.

The statements required from those who compete for field crops, must be sent to the Recording Secretary, Albany, previous to the 1st of January, 1843, and the premiums will be awarded at the annual meeting of the Society, on the third Wednesday in January.

It is very desirable that all those who intend to compete for the premiums on butter and cheese, maple sugar, cocoons, silk, &c., should have their specimens in Albany early on the morning of Sept. 27, that they may be deposited in their appropriate places, and the rooms suitably arranged on the day previous to the Fair.

All premiums will be paid in cash or note at the option of the winner.

The premiums for essays, to artists, and for agricultural implements, will be open to the United States; but all others will be confined to residents of this State, who are members of the Society, or who may become so by the payment of one dollar on entering their articles.

Competitors for the premiums on essays may forward their manuscripts to the Recording Secretary, Albany, previous to the first of June, 1843, free of postage.

A Doubter.

The philosophic Tucker divides mankind into two great families, the Knowalls and the Searchers. Our correspondent S. W. places our friend David Thomas among the latter, a very respectable connexion indeed, but not a numerous one. We suspect that some of the same blood runs in his own veins. The Knowalls in this world have a remarkable comfortable time of it; but the Searchers, a meddlesome set of dogs, are always making difficulty for other people and never satisfied themselves. O! for a pope and an infallible church—in agriculture we mean—certainly we would not say any thing about a Babylonish lady, whose character and pretensions have been among the saints so long a matter of discussion. But if we only had an infallible agricultural head, every thing would be quiet and comfortable; this terrible inkshed would cease; and our quills, instead of being worn to the stump in inditing many a goose's lucubrations, might repose quietly in the wings of those branches of the family to whom they originally belonged.

"D'Alenbert said that the first qualification for a Philosopher was the faculty of doubting. As unreasonableness induces us to embrace every absurd improbable theory, so does the faculty to doubt enable us to scan every theory, both by the tests of scientific proof and the sober lessons of practical experiment. David Thomas is clearly one of the number of those individuals in whose mind this cardinal qualification of the philosopher is most fully developed. In some of his communications on botany, he has sometimes noticed the small blunders and marvelous conceits of certain *cammoisseur* writers, with a spice of humor and pleasantry suited to the nature of the offence; but in this address, given in this month's Farmer, which relates to the all important theory of the nature and action of manures, he has taken up the theory of Professor Liebig, in relation to the mysterious action of plaster on vegetation, and shown most conclusively from his own experience, and the general experience of our whole rural population, that the theory of the learned professor is at least shaken by long established and often repeated experiments." S. W.

It is a curiosity to find a man who places too low an estimate on his own abilities.

Sugar from Indian Corn and Stearine from Lard.

We have received from the Commissioner of Patents, always on the alert to collect and diffuse useful information, an Essay on the manufacturing of Sugar from the corn stalk by William Webb of Wabington, Delaware; and a communication on the subject of Oil and Stearine from Lard—in a pamphlet published by the National Agricultural Society. They are highly interesting and valuable. We shall select only those parts which are directly practical; omitting such as may be considered too scientific for general readers. The prospects which they hold out, especially in respect to the product of sugar from maize, are very highly encouraging. The first step only in the process is as yet taken; and especially it remains to be seen what are to be the expenses of the process. It is confidently stated that eight hundred or a thousand pounds of sugar may be produced up in an acre of corn, planted as Mr. Webb directs. We shall be ready to believe it when it is done; in the mean time we design not the slightest impugning of Mr. Webb's integrity and intelligence, and caution no distant or doubtful, which should interfere with the immediate and faithful trial of the experiment. Heaven grant that these expectations may be realized on the care of humanity for no other reason, if human comfort is taxed and human life used up so cruelly and so prodigally, as it is in this pamphlet represented to be in the manufacture of sugar from the cane.

I have felt considerable interest in the plan for extending the cultivation of sugar in temperate climates, and have made many inquiries; first, upon the Beet, and recently upon Maize, or Indian corn, in the hope of discovering some mode by which the desired end might be attained. The results from the latter plant have been extremely encouraging. The manufacture of sugar from it, compared with that from Beet, offers many advantages. It is more simple, and less liable to failure. The machinery is less expensive, and the amount of fuel required is less by one-half. The quantity of sugar produced on a given space of ground is greater, besides being of better quality.

The raw juice of Maize, when cultivated for sugar, markets 10¢ on the stone (one ton) while the average of cane juice (as I am informed) is not higher than 8¢, and beet juice not over 7¢. From 50 qts. (dry measure) of the former, I have obtained 4 pounds of sugar, or 80 lbs. of syrup, as denominated to the point suitable for crystallization. The proportion of crystallizable sugar appears to be larger than is obtained from cane juice in Louisiana. This is accounted for by the fact, that our climate ripens corn perfectly, while it rarely if ever happens that cane is fully matured. In some cases the syrup has crystallized so completely, that less than one sixth part of molasses remained. This, however, only happened after it had stood from one to two months. There is reason to believe that if the plant were July ripe, and the process of manufacture perfectly performed, that the crop might be entirely crystallized without the use of molasses. This perfection in the manufacture cannot however be attained with the ordinary apparatus. Without any other means for pressing out the juice than a small hand-mill, it is impossible to say how great a quantity of sugar may be produced on an acre. The experiments have been directed more to ascertain the mechanical quality of the corn stalk, than the amount a given quantity of ground will produce; but the calculations made from trials on a small scale, leave no room to doubt that the quantity of sugar will be from 800 to 1,000 pounds.

Another mode of cultivation, to be employed in combination with the one first proposed, consists simply in raising a greater number of plants on the same space of ground. By this plan, all the unfavorable results above mentioned were obtained; a much larger quantity of sugar was produced, and of better quality.

The juice produced by this mode of cultivation is remarkably pure and agreeable to the taste. Samples of the sugar yielded by it are now in the Patent Office, with a small hand-mill by which the stalks were crushed.

On the whole, there appears ample encouragement for perseverance; every step in the investigation has increased the probabilities of success—no con-

dition having been discovered why it should not succeed as well, if not better, on a large scale, than it has done on a small one. In the first place, it has been satisfactorily proved, that sugar of a excellent quality, suitable for common use with all returning, may be made from the stalk of Maize. 2d. That the juice of this plant when cultivated in a certain manner, contains an elastic matter remarkably free from foreign substances. 3d. The quantity of this juice, (even supposing we had no other evidence about it) is sufficiently demonstrated by the great amount of nutritive grain which it produces in the natural course of vegetation.

It is needless to expatiate on the vast advantages which would result from the introduction of this manufacture into our country.

Grapes are too used in the West, in such overflowing abundance, that the markets become glutted, and inducements are offered to employ the surplus produce in distillation. This business is now becoming desirable. The happy conviction is spreading rapidly, that the use of alcohol as a beverage, instead of conferring to health and strength, is the surest means of destroying both. Some other production, therefore, will be required, in which the powers of our soil may be profitably employed. This, it is hoped, will be found in the business now proposed. Instead of distilleries, converting food into poison, we may have sugar houses, commencing at our doors an article in universal demand, not merely useful, but necessary; furnishing as it does one of the most simple, natural, and nutritious varieties of human sustenance, found in the whole range of vegetable production. It is said that the general use of sugar in Europe has had the effect to extinguish the scurvy, and many other diseases formerly epidemic.

The time of the crop in the sugar island, (saye India) is a season of gladness and festivity to man and beast. The meagre and sickly among the negroes exhibit a surprising alteration in a few weeks after the mill is set on motion. But though the use of sugar is attended with all these agreeable effects, there is no agricultural production furnished in so great a service of human life. The reason of this moiety may be found in the climate, and the peculiar situations in which cane is cultivated. How much then will be taken off the load of human suffering, if this article can be produced in more temperate and healthful regions! The wide prairies, and fertile alluvial valleys of the West offer an ample field, rich with all the elements of success.

It may be doubted whether a tropical country can ever furnish a great amount of exports, (except through the means of compulsory labor. It appears then, highly probable, that if the inhabitants of temperate countries wish to continue the use of sugar, they must find some means to produce it for themselves. The Beet appears to succeed well in Europe, and the manufacture from it is extending rapidly; but there is no hazard in making the assertion that Indian corn is far better adapted to our purpose.

The following mode of cultivating the plant, and working the sugar, is the best that can now be offered.

The kind of soil best adapted to corn is so well understood, that no directions on this point are necessary; except that it should be rich, the water the better; it need not be fertile, manure must be applied either ploughed in or spread upon the surface, or used in any ways, according to the ability of the owner. Sowing can be done at any preparation for the crop, after a clear and well turned under, and harrowed fine immediately before planting.

Select for seed the largest and best ears of any variety of corn you disposed to throw up, and spread it in branches; that kind most productive in the neighborhood, will be generally the one best adapted to the purpose. The planting should be done with a drilling machine. One man with a pair of horses, and an assistant of this kind, will plant and cover, in the most perfect manner, from ten to twelve acres in a day. The rows (if practicable, let them run north and south) two and a half feet apart, and the seed dropped sufficiently thick in the row to insure a plant every two or three inches.

A large harrow made with teeth arranged so as not to injure the corn, may be used to advantage soon after it is up. The after culture is performed with a cultivator, and here will be perceived one of the great advantages of drilling; the plants all growing in lines, perfectly regular and straight with each other, the horse-hoe cuts the earth and cuts up the weeds close by every one, so that no hand-labor will be required in any part of the cultivation.

It is a part of the system of cane planting in Louisiana, to raise as full a stand of cane upon the

ground as possible; experience having proved that the most sugar is obtained from the land in this way. As far as my experience has gone, the same thing is true of corn. This point must therefore be attended to, and the deficiency, if any occur, made up by timely replanting.

The next operation is taking off the ears. Many stalks will not produce any, but wherever they appear, they must be removed. It is not best to undertake this work too early; as when the ears first appear, they are tender, and cannot be taken off without breaking, which increases the trouble. Any time before the formation of grain upon them, will be soon enough.

Nothing farther is necessary to be done until the crops are ready to cut for grinding. In our latitude, the cutting may commence with the earlier varieties, about the middle of August. The later kinds will be ripe in September, and continue in season until cut off by frost. The stalks should be topped and bladed while standing in the field. They are then cut in bundles, and taken to the mill. Fine tops and blades, when properly cured, make excellent fodder; and better it is believed, than any hitherto used; and the remainder, after passing the rollers, may easily be dried and used in the same way; another advantage over the hay, which, after the juice is expressed, is usually burned.

The mills should be made on the same general principle employed in constructing those intended for grinding corn. An important difference, however, will be found both in the original cost, and in the expense of working them. Judging from the comparative hardness of cane and corn stalk, it is believed that one fourth part of the strength necessary in the construction of a cane mill, will be amply sufficient for corn; and less than one fourth part of the power will move it with the same velocity. It may be made with three upright wooden rollers from twenty to forty inches in length, turned so as to run true, and fitted into a strong frame work, consisting of two horizontal pieces sustained by uprights. These pieces are mortised to admit wedges on each side the pivots of the two outside rollers, by which their distances from the middle one may be regulated. The power is applied to the middle roller, and the others are moved from it by means of cogs. In grinding, the stalks pass through in the right side of the middle cylinder, and come in contact with a piece of frame work called the dash-board, which forces them backwards so that they pass directly the rollers again on the opposite side of the middle one. (See cut.) The modern improved machine is made entirely of iron; three horizontal rollers arranged in a triangular form, one above and two below, the cane or stalk passes directly through, receiving two pressures before it escapes. The lower cylinders are contained in a small cistern which receives the juice. The latter machine is the most complete, the former the least expensive. These mills may be moved by cattle, but for large operations, steam or water power is preferable. When the vertical cylinders are turned by cattle, the axis of the middle one has long levers fixed across it, extending from ten to fifteen feet from the centre. To render the same firm, the axis of this roller is carried up to a considerable height, and oblique lances of wood by which the oxen or horses draw, are extended from the top of the vertical axis, to the extremities of each of the arms. When horizontal cylinders are propelled by animal power, the upper roller is turned by cogs at one end, which are caught by cogs on a vertical shaft. It is said that in the West Indies, the purest cane juice will ferment in twenty minutes after it enters the receiver. Corn juice has been kept for one hour before boiling, without any apparent injury resulting;

at so much delay is not desirable, as it may be attended with bad effects.

"The process which has been employed in the manufacture of *Maize* sugar, is as follows: The juice, after coming from the mill, stood for a short time to deposit some of its coarser impurities; it was then put off, and passed through a double strainer, in order to get rid of such matters as could be separated in this way. Lime water, called milk of lime, was added in the proportion of one or two table spoons full to the gallon. It is said by sugar manufacturers, that knowledge on this point can only be acquired by experience; but I have never failed in making sugar from employing too much or too little of the lime. A certain portion of this substance, however, is undoubtedly necessary, and more or less than this will be injurious; but no precise directions can be given about it. The juice was then placed over the fire, and brought nearly to the boiling point, when it was carefully skimmed, taking care to complete this operation before ebullition commenced. It was then boiled down rapidly, removing the scum as it rose. The juice was examined from time to time, and if there was no appearance of foamy particles which would not rise to the surface, it was again passed through a double strainer. In judging when the crop was sufficiently boiled, a portion was taken between the thumb and finger, and if when moderately cool, a thread half an inch long could be drawn, it was considered to be crystallized, and was poured into broad shallow vessels to dry. In some cases crystallization commenced in twelve hours; in others, not till after several days; and in no case was the process completed as to allow the sugar to be drained in less than three weeks from the time of boiling. The reason why a great length of time was required, I was not yet best able to discover. There is no doubt that an improved process of manufacture will cause it to granulate as quickly as any other.

"Enough has been said to enable any one to dispose of the manufacture of sugar from *Maize* on a large or small scale. As the profits of the business, I shall make no positive assertions; experience on the subject is yet too limited to warrant them; and as all the facts in relation to it are now before the public, every one interested can draw his own conclusions. It is said by those acquainted with the cultivation of the cane, that that business cannot be carried on profitably on less than one hundred acres in crop, and attempts on a small scale will be certain to fail with a great loss of time and labor. How far this may be applied to corn, remains to be seen.

"Some comparison between the cultivation of cane and that of corn may perhaps be interesting.

"The cane lands in Louisiana are redeemed to agriculture, by steeper embankments along the river, and by numerous ditches, which extend back into the swamp to a considerable distance beyond the line of cultivation. The ground is still further divided by smaller ditches into lots of from one to two acres in extent. It is extremely rich and productive; but the expense of draining, and keeping up the embankments, must be very considerable; this forms the first difference to be noted in the culture of the two plants under consideration.

"The best season for planting cane in Louisiana, is in the fall, which is also the time of harvest, when labor is most valuable, and the greatest exertions are required to secure the crop before it is destroyed by frost. But the most striking difference will be found in the cost of seed, and in the labor of planting. The cane is propagated by layers; these are partly furnished from the tops of the plant, when cut for grinding, but are principally ratoon. Of the latter, it requires the produce of one acre to plant three. The rain from one acre of corn will be sufficient for planting forty acres. Therefore, the difference in expense for seed, will be some to thirteen.

"In planting cane, furrows are made with the plough from two and a half to three feet apart; in these the layers are placed in a double row, and the earth drawn over them with hoes to the depth of three or four inches. In the spring, before the plants are up, this covering is partly scraped off, so as to leave them buried from one to two inches.

"From this account, it is evident, that no more manual labor will be required to drill fifty acres in corn, than to plant one acre in cane. The labor of cultivating the latter plant during its growth is also greater; but this may be balanced by the extra work required to take off the embryo ears from the corn. When cultivated in the mode recommended, the stalk of corn is soft, remarkably heavy, and full of juice from bottom to top. The amount of power required for grinding them must be much less than is necessary

for cane—or, what is the same thing, an equal power will do it with greater rapidity. The average yield of cane in Louisiana, is one thousand pounds of sugar, and forty five gallons of molasses per acre.

"From the above comparative statement, it would appear that one half the amount of crop from corn would be equally, if not more profitable.

I will only add in conclusion, that whether or not sugar from the corn-stalk may soon become an article of profitable export—its manufacture in the simplest form will enable every family to supply themselves with this article for common use, now become so much a necessary of life, and thus save a considerable bill of expence yearly paid for foreign sugars.

(Translated at the Patent Office, and highly confidential of Mr. Webb's Esqy.)

H. L. ELLSWORTH.)

Extract from *Annales de la Société Polytechnique*, *Prologue*, No 22, for October, 1-39.

SUGAR OF CORN.—There is no plant of greater general interest or utility than Indian corn. It can serve, under a great variety of different forms, for the enrichment of man and the domestic animals, and above all, the application of industrial sciences.

In reference to its saccharine qualities, *Maize* has not been sufficiently appreciated. The cultivator reaps, that under the tropics the stalk of this plant is so very succulent that the Indians suck it as in other places they do the sugar cane.

M. Pallas, who has made a great many researches on this application of *Maize*, has arrived at a remarkable result—he has found by many experiments both in France, and more recently in Africa, that this vegetable, by a simple modification applied to its culture, is able to furnish a much more considerable quantity of sugar, than by the ordinary method.

This method consists in detaching from the plant, immediately after the fecundation of the ovaries (after the plant has inselled) the young ear, and to leave it to develop itself thus deprived of its fruit. Arrived at maturity, the stalk of the Indian corn contains crystallizable sugar in quantity very often double that obtained when the plant is left to mature with the grain. In fact, by the ordinary mode of culture, the grain is nourished at the expense of the sugar in the stalk, as it absorbs a great quantity of this immediate principle, which, by the process of nutrition, is converted into starch. On the other hand, if the young ears are immediately destroyed, the sugar intended to nourish them remains in them where it accumulates, and the *Maize* plant is thus converted into a true sugar cane, while the fibrous part can be manufactured into paper.

The quantity of sugar is so very great in the stalk of the *Maize* deprived of the ear, that the pulp of this vegetable retains a sensible flavor of sugar even after it has been dried, and is easily obtained by examining the specimens deposited by M. Pallas in the Bureau of the Academy of Sciences. These results are so important as to merit experiments on a grander scale, which may obtain thus for France a source of new industry in the manufacture of sugar.

We give no extracts on the subject of obtaining Stearine from *Lord* for the purpose of making candles equal to wax, as it would not be generally intelligible and is adapted to the manufacture upon rather a larger scale than could be used in families, as the patentee advises that "To operate with advantage, the vessel in which the boiling is effected should be of considerable capacity, holding say from ten to a hundred barrels"—or about as large as a common log cabin. We have no reason to doubt the success of the process.

Carrots.

These are one of the most important crops a farmer can cultivate, whether for his dairy, young stock, sheep or swine, or whether they are considered as a crop which yields rich remuneration for his labor, or as one leaving his land in a healthful and active state when taken off. They succeed as well, and perhaps better, when sown successively on the same soil for many years. The ground for them should be deeply and thoroughly pulverized, and then they will send their long roots to a depth which the spade has not penetrated, thus to some extent, imitating the work of the subsoil plough by breaking the hard soil beneath them.

Carrots for stock should be sown early, before the

spring and summer droughts, which are very injurious to them, come on. The best manure we know of for them, is that recommended in No. 2, present vol. of N. G. Farmer, for gardens. If this is not convenient, mould from the wood, answers a very good purpose. They must be thinned and kept very clean, which in fields may be done with a corn harrow or cultivator.

W. B.

Mount Osceola, April, 1842.

Milberry Trees and Silk Culture.

An old friend of ours, Gen. Dickinson of Deerfield, Mass., desires us to say that he has 100,000 of milberry trees, of the Canton, Multicaulis, Moretti, and several hardy varieties, which he would be glad to dispose of on the most reasonable terms. The public mind must presently be aroused to the importance of silk raising and this most valuable article of culture. The apathy and incredulity of the public in regard to it is deplorable. They seem now like a bird and founded horse, whom you can neither by coaxing or driving even get into a trot. What may be accomplished under a new ruler and since the Commissioner of Patents has mounted the silk horse, with bright spurs and a new whip, we shall see. We only add that whoever deals with Mr. Dickinson, may, we are satisfied, rely entirely upon his honor.

The Le Roy Female Seminary.

Mr. Emmon—In some of the early numbers of the New Genesee Farmer, a correspondent attempted to show that Female Seminaries of the present day are unsuitable places for farmers' daughters, and that a modern liberal education is calculated to make them dissatisfied with their country homes and rural life; and in your intercourse with the agricultural community, I doubt not that you find the same opinions quite prevalent, especially among those who, being destitute of a good education themselves, are ignorant of its true value and influence, and know nothing of those institutions against which they disclaim.

It is not my present intention to expose the fallacy and injurious tendency of such sentiments, but merely to express a regret that all who cherish them could not have the privilege which I enjoyed last week, of witnessing the examination at the Le Roy Female Seminary, under the management of Miss Emily E. Ingham, Principal. The catalogue of pupils for the past year shows the number to have been 232. The winter term closed on the 15th of April, with four days public examination. Each class in the school was examined separately and thoroughly in the various branches of study, and each pupil, excepting the junior class, read a composition of her own production. The proficiency and depth of research manifested by the pupils in their examinations, and the knowledge, talent and sentiment displayed in their compositions, reflected the highest credit on the teachers, and I gave conclusive evidence that they had been eminently successful in their avowed aim, "to make thorough scholars, independent thinkers and reasoners, and useful members of society."

Many of the pupils are farmers' daughters, and if their parents were asked whether they think the instruction imparted at this institution is "calculated to make them discontented and unhappy," I have no doubt their reply would be in substance like the expression I heard made by a worthy farmer from Livingston, who had come to witness the examination and take home two lovely daughters, in parting with the principal and teachers his last words were, "my only regret is, that I have not more daughters to send you."

The next term of this Seminary commences on the first Wednesday of May.

B.

"See his Report in our last number."

FLOWERS.

The following is a pretty poem received from fair hands, which, we hope, will suit others for our use, even sweeter and more fair.

For the New Genesee Farmer.

The following lines were suggested by the perusal of an article on Floriculture in a late number of the New Genesee Farmer.

Flare the flowers, the fair young flowers,
Where'er their dwelling be;
Though springing in the mountain side—
Or 'neath the greenwood tree.

Though found in each sequestered nook,
Of every woodland shade;
Or blooming 'mid the gay parterre,
By tasteful fingers made.

A pleasant task it is, I ween,
The fragrant things to rear,
Whose wealth of radiant loveliness,
Life's weary hours may cheer.

To watch the opening buds that spring,
"Nest summer's genial showers;
Each striving in its blushing pride,
To bloom the fairest flowers.

And when at last the blossoms lie
All withered at our feet,
And tawny in the pressing breeze
Their perfumed odors sweet;

There comes from every fading flower
A lesson for the heart,
That earth's most fair and lovely things
"The soonest must depart."

"For careless teachers are they all,"
And emblem too, of youth,
Its days of infant purity,
Its trusting years of truth.

And like the human flowers that spring
In luxury 'round our hearth,
Till, fed from our sight-away,
We know not brief their worth.

J. L.

Rural Life and Pleasures.

MR. COLMAN—

Your correspondent, Zelia, says that our date and interest should prompt us to bestow our co-operation to make your columns instructive and interesting; and that this cannot be fully attained unless your female readers render some assistance.

With an imperfect education, I feel much diffidence in presenting you this communication. But since my education taught me to perform every known duty, I am most happy to render my part, humble as that may be. The offering, if not accepted for its intrinsic value, may be welcome for the good intentions which dictate it. I have not the vivid imagination and enviable sensibility of W. B., nor the fund of interesting ideas of Zelia; but I hope I may be allowed to claim for myself a grateful and holy reverence for my Creator, and a thirst for improvement in science, in literature, in floriculture and horticulture, in rural and domestic economy, and finally, in every thing that pertains to the development of human virtue, the advancement of good morals and the present well-being and future happiness of mankind. An attention to flowers and shrubs, service to inspire a taste for natural beauty every where, and for all that is delightful and lovely in the works of our Creator. It is our duty to cherish and strengthen and nourish the benevolent affections, and a sympathetic attachment for all that is around us. Much certainly is to be done for many of us, in order to prepare our minds for enjoyment in the works of nature, in erasing our false ideas and prejudices in relation to the true sources of our best and purest pleasures. A ramble through the green fields and over the hills, may be prompted by mere listlessness or accident, or if you please, by romance or fashion; and without some cultivated taste for rural scenery or some sympathy with nature, we may not feel in such case a single emotion of heart felt enjoyment, nor one grateful or reverential aspira-

tion of the soul to heaven, for the infinite abundance and exquisite and countless forms of beauty which are spread around us.

But we cannot expect every one to look upon nature as in every department and object alive with the presence of God, nor to feel deeply conscious of the great source from whence these pleasures flow, and happy always in this recognition of the divine goodness. But I should rejoice, if any motive, even of an inferior character, would induce them to spend some part of their time in the fields and the garden and the forests, by the silver stream and by the mirrored lake, rather than that they should not do it at all. But in order to taste the deep and exhaustless fountains of pure bliss, enclosed, if I may so say, within the folds of every shooting plant, or under their full developed leaves, amidst all the secrets and all the wonders of vegetable life, we must feel and reflect and meditate upon the design and intentions, for which their author formed them, and the sublime and happy influences, with which they are capable of inspiring our minds. It is with peculiar pleasure I peruse an occasional line from the pens of a few of the many gifted females of our happy and privileged country. May they dig deep for the rich stores of intellectual wealth within their reach, and bring them forth to adorn and bless the community. They cannot exert their talents too much in order to render rural scenery attractive and rural life delightful; and to show how much its pleasures and privileges are to be coveted.

Happy is the condition of that rural retreat, where the peaceful labors of agriculture and the calm pleasures of country life divide the hours; where abundance comes as the harvest compensation of labor; contentment springs out of an innocent mind and a guiltless conscience, and simple mirth and youthful glees are but the pourings out of a full heart, like the bubbling and sparkling waters from a gushing spring. It is delightful to see the love of nature in her simplicity, in her beauty, in her variety, in her grandeur, in her glory, highly cultivated and strengthened; to pour our hearts out in grateful admiration and wonder at the exhibitions and testimonials of the divine bounty in the fields, the forests, the fields, the fountains; in the multiplied forms of life every where crowding upon our sight, and every where manifesting their own enjoyment of existence: in the budding and flowering foliage of spring, in the golden and ripened harvest, in winter's glittering mantle, in the reddening dawn, in the gorgeous sunset, and in the star spangled night. When to such tastes these are added stores of intellectual wealth, constantly increasing, the charms of unbroken and warm domestic affections, the mingling of sympathetic hearts, which in every kind and every elevated emotion, vibrate in harmony, and with all a deep and grateful sentiment of dependence and duty to the great and exhaustless source of all happiness, where on earth shall we look for a condition more privileged and blessed; what stimulants does it furnish to virtuous industry, and what all vibrations to those pains and afflictions which are inseparable from our humanity.

FLORA.

Zelia's Domestic and Political Economy—
Rural Taste, &c.

MR. COLMAN—I felicitate you on the acquisition of such a female correspondent as Zelia; her lessons on domestic economy if lived up to, will do more towards curing hard times, and commencing a healthy social reform, than a hundred essays on political economy, or twice that number of common-place high tariff or home league resolutions; in fact, stern necessity alone is now dealing with the people, and bringing about that state of things which Zelia would effect by moral suasion, and the beauty of her own in-

dividual and may I not say, truly intellectual example.

Since "foreign goods and trinkets" cannot be paid for any longer in paper contrivances, prices in New York have fallen so ruinously low, that next to none will now be imported for the remainder of the fiscal year; and the great puzzle now is with our national financiers, how they are to raise a revenue at all, if they increase the present tariff of duties, since large quantities of foreign goods are now being reshipped to avoid the payment of our present tariff; what a blessed thing it is that all foreign balances against us can now only be paid in coin, as nothing short of this would have stopped importations; a call for specie strikes at the life of our Banks, and they are so averse to dying, that they had rather see all the ladies in the country go without broader shawls and velvet cloaks, than to lose even a note of their coin.

Who is so blind as not to see in this state of things a better and more lasting encouragement to silk culture and home industry, than all the special legislation Congress could bestow in the shape of high tariff, or still more senseless retaliatory restrictions? "What has England's high tariff restrictions done for her, but increase the volume of her population, her paupers and her poor rates? Her manufacturing industry has been stimulated by protection, until it was necessary to give to her agriculture like protection, in order to make her independent of other nations for bread, and also to stimulate the home market for her surplus manufactures. Let us then in these United States, with our vast territory, our endless rolling prairies, and superior sunny climate, be slow to think that we have the same need of restrictions on trade, as little, cold, wet, over populated Great Britain!

Zelia inculcates domestic simplicity and economy, in a manner which shows that she has arrived at the corner stone of political economy almost without knowing it; her lessons show that simplicity in domestic arrangement is the true handmaid to mental culture, that meretricious display and fashionable excess, can hardly conceal vulgarity of mind, or make up for a deficient education. I hope Zelia will write often for the Farmer; let her tell her log house sisters, to keep their scanty furniture "bright and clean"; a little white wash both within and without, a clambering vine, a grass plot, a garden with a few flowering shrubs and plants, will speak a much better civilization and mental culture, for the unknown inmates of that cabin, than the most ambitious farm house in the land.

S. W.

Floriculture.—*Campanula rotundifolia*.

MR. COLMAN—I have ever read with a great deal of interest the articles in your Journal on the flowers of spring, summer and autumn.

I have admired the unbiased judgment and fine taste, which led the writer of those sketches to place—not only in his garden, but in his list of flowers—side by side with imported exotics, our native *Hepatica triloba*, *Sanguinaria Canadensis*, *Lobelia cardinalis*, and even the neglected *Macrorrhynchus racemosa*, and many other native beauties usually overlooked.

But I have looked in vain for any reference to one lovely indigenous flower, and can only excuse this neglect of my favorite by supposing the gentleman a stranger to its existence. If this be true, I am certain he would not object to an introduction.

If on some bright day in June, he will go with me while my oxen rest from the plough, to one of the woody uplands of Genesee county, where the underwood is thickest and the soil so mixed with flints that a blade of grass can hardly grow, we should occasionally discover a little blue bell about the size of an acorn hanging on a stalk a few inches in length, and so slight as to be moved by every breeze. If he will

en return with me, I will show him the magical effects of cultivation on the same plant.

Two seasons have passed since one of these wild-
wrens was transplanted to our garden. I hardly
pected to see it live; but in the place of one low
alk, and one bell, from that same root we had, last
summer, from June until October, a succession of
wers growing on stalks from two to three feet high,
d often three bells on a stalk. I one day counted
ry.

Notwithstanding the change in the flower-stalks,
bells seem in no wise changed, but retain all their
iginal delicacy, thus proving to a demonstration that
ey have not, like many other *bells*, been injured by
mination.

I know not its botanical name, or if it have any—
an admire it without one—but it has beauty enough
tainly, to compensate for the longest and homeliest
t that any Botanist ever invented. E.

Le Roy, March 11th, 1842.

The plant to which our correspondent refers, is one
tich we think from his account, we have seen
d admired, and which we suppose equals the
tanical name of *Campanula rotundifolia* or Flax
ll-flower. Its name, *campanula*, signifies its bell-
ppo. It is among a class of flowers easily trans-
ferred to the garden, and greatly improved by cultiva-
n. Beck's Botany describes it thus: *Stem*, 8—12
ches high. Radical leaves cordate (withering
ly). *Flowers* few, large, blue, in a loose terminal
vide or raceme. (If E. will send us one of the
ossoms when they appear, in a letter or paper, he
ll oblige us, and we can ascertain the name.)

Large Breed of Hogs in Clyde.

Clyde, February 21st, 1842.

R. EDITOR—

DEAR SIR—I have a breed of hogs that grow to a
ge size, one of which about two and a half years
I killed on the 14th inst., that weighed when
essed 833 lbs., of which 7½ lbs. was lard, and the
me weighed 56 lbs. each.

I commenced feeding him about the middle of
vember with peas and corn, at which time he was
low condition. When alive, he measured 6ft. 8in.
round his body just back of the fore shoulders. The
ight of this animal sounds large to us in this neigh-
hood; and if you consider him deserving of it,
a will no doubt pay him the compliment of a note
in your useful paper, the New Genesee Farmer.

Your obt' servant,

JOHN POTTS.

This hog certainly deserves a memorial, and is
rthy of being an Emperor among his own country-
n. He must have taken a lesson of the frog, who
d to equal the ox, but with a good deal more ease,
s and without ending in the same unhappy explo-
n. He was as heavy when dressed as fat as the
en that are killed. Our correspondent does not
e his breed of swine a name; and it might be
med unwell to call them the Potts breed; but con-
sidering the value of such pork for boiling, we might
forgiven if we should call them the Pot Breed.
at's "doing the thing to a U."

The Ne Plus Ultra.

Since giving a notice of the Clyde Breed of Hogs
m Mr. Potts, we have received the subjoined from
correspondent in Maine. The Yankees may well
of this "Beateum;" and it will be a small affair
any other state to talk of "going the whole Hog"
r this. The amount of loss in killing is very small
contradicts the usual experience.

Maine Pig vs. Genesee Pigs.

Mr. Adams, in the last number of the New Genesee
rmer, says "Mr. Marks had four Berkshires which
ighed 1838 pounds, and Mr. Corter's two weighed
60 pounds, when twenty months old." Now, Mr.

Editor, I have a tale to tell worth two of that. Mr.
Jansson, of this place, yesterday killed a pig twenty
two months and twelve days old, which weighed
alive 1010 pounds. Dressed he weighed 905 lbs.—
without the earl, that weighed thirty eight and a half
pounds. Making his whole weight 943½ pounds—a
loss of only 66½ pounds. He was a cross of the
Berkshire and Bedford—girted seven feet, and was
five feet and about ten inches in length. His keeping
all September last, was not high or expensive. Six
bushels of potatoes and two of meal, with weeds and
the spare milk of three cows, lasted him and two
breeding sows of the same age, two weeks. They
were fed but twice a day. The potatoes were boiled,
mashed up in a large tub, the meal added and water
enough put in to make it quite thin. In addition to
this feed night and morning since September, he has
had three quarters of corn at noon.

Your obt' serv't

WM. WATERMAN.

Cornish, Me., March 25, 1842.

Ornamental Trees.

[From Colman's Fourth Report.]

The cultivation of ornamental trees ought to be
strongly pressed upon the farmers. "Put a tree
down; it will be growing while you are sleeping."
Many of them enrich the country; all adorn it,
and thus essentially increase the value of an es-
tate, and render the country more healthful as well
as beautiful. Every place on a farm, where they
can grow without injury to the crop, ought to be
planted with trees. Timothy Walker, of Charles-
town, Middlesex county, lately deceased, left a
legacy of some hundred dollars to be expended in
planting ornamental trees on some of the great
roads in that town. This was a noble bequest;
and places him among the benefactors of the com-
munity. It is an example worthy of imitation.
A taste for the beauties of natural scenery can-
not be too much cultivated among us. A taste for
natural beauty is closely allied to a taste for moral
beauty. The more attractive our homes are ren-
dered, the more shall we love our homes; and the
love of home is the parent of many kind and no-
ble affections.

A taste for natural beauty is an original element
of the mind. It may be strengthened, elevated,
and enlarged by education; but it appears even in
the rudest minds, and thus speaks its divine origin.
I believe the perception of beauty exists in all ani-
mals; or why should they have been made so
beautiful?

Natick in Middlesex Co., was the seat of the first
Christian mission to the Indians, where the benev-
olent Eliot, designated as the Apostle, sought to
pour into the minds of these children of nature,
benighted with the thick darkness of superstition,
the heavenly rays of inspired truth. Eliot was
followed by a worthy successor, Oliver Peabody.
The Indians appreciated the blessings of the religion
of peace and love which he taught them; and in
gratitude for his services, these sons of the forest,
to whom the trees seemed as their own kind-
red, came in a deputation bringing two elm, and
asked leave to plant in front of the humble dwell-
ing of the missionary these "*trees of friendship*."
This was in 1722, and these trees stood for ninety
years, when one was rived by lightning, and the
other seemed to perish through sympathy. When
the successor of Mr. Peabody, Mr. Badger, was
settled in 1753, the Indians offered the same token
of respect and the same pledge of good will to
him. These trees are still in full vigor, and remain
as beautiful monuments of affections, which
have gone out on earth, but are destined to be re-
kindled and burn with a purer flame.

Nature is every where prodigal of beauty, as if
she would stimulate the passion for it to the ut-
most extent. Among the varied combinations of
charming objects, which mingle in a rural land-
scape, the trees are preeminent. Sometimes rising
in single cones so exact and symmetrical in their
form, that they seem the perfection of art; some-
times spreading their umbrella-like limbs in curves
and lines of the most graceful expansion; some-
times bending their boughs to the earth loaded
with golden and crimsoned fruit, and when the sun
pours its bright rays upon them, presenting not an

imperfect image of that sacred bush where the divine
presence wrapped itself in robes of fire; sometimes
seen in long single lines skirting the traveler's
path; sometimes in beautiful clumps and clusters,
affording a grateful shade to the panting herds;
at other times in the wide spread forest, shading
a valley with their deep and black green; here
again furnishing the mountain's side with their
thick and matted foliage; now in autumn robed in
the gorgeous vestments of more than oriental mag-
nificence; and often in winter bending under their
pile-up fleeces of snow, or glistening with match-
less splendor when cased in ice and changed into a
crystal forest of glass and diamonds; in all these
cases how suited are the trees to charm the eye and
delight the mind! Why should not the eye be
charmed? Why should not the imagination be
delighted? Why should we not take pleasure in
the beauty of God's works? Why should we not
do what we can to make our homes continually
more and more beautiful; and to multiply and fill
to overflowing these innocent sources of pleasure?

The country is full of poetic sentiment and re-
ligious monuments. The civilized inhabitants of
the country should seek to rise above the mere
drudgery of life, and make themselves familiar
with nature in her ever varying and charming as-
pects. It will not hurt their industry, but it will
cheer their toil to study the benevolence of the
Creator in the perfection of all his works; and, I
trust I may add without irreverence, to second his
provision for the happiness of his creatures in
multiplying every where around them the forms of
beauty.

I hope I shall be pardoned for the enthusiasm
which I may betray on this subject. Let those
who think my remarks out of place, kindly pass
them over. Penetrated to the depths of my soul
with a sense of the beauty of nature and the
"charms of rural life," my anxious soul for the
lowest laborer may have had his toil alleviated by
his self-expected quickened, and a sentiment of the dig-
nity of his own nature breathed into his heart by
a habit of observing and studying and enjoying
the wonders and glories of the visible creation
around him. I cannot think it difficult, under a
just education, to awaken this sentiment and form
this habit, even in the humblest minds; and what
sources of gratification in such case shall we open
to him, which the wealth of cities cannot purchase,
and what motives to religious trust and joy shall
we inspire, which written teachings can never im-
part. For what a prodigality of beauty is every
where manifested in the natural world! Light-
self is the perfection of beauty, and wherever it
spreads its glittering rays, it commands every thing
which it touches into beauty. Take the great ele-
ments of nature, the earth, the water, the sky, the
sun, the moon, the stars; and what beauty is re-
splendent in every one of them. Take the vege-
table tribes, the trees, the flowers and the verdant
fields; take the animal creation, from the fairy
bird that cleaves the liquid air with his burnished
wing, to the pearl of exquisite brilliancy, that lies
buried in the depths of the sea; and what a divine
beauty shines out in the whole. Examine the mi-
nutest atom, which you can pick from the earth
with the finest needle, the smallest flower that
drinks in the refreshing dew, the least insect that
floats in the sun-beam, the tenderest leaf that
quivers in the breeze, and the vast continent with
all its mixed and varied features of land and water,
of valley and mountain, of prairie and forest;
take the vast ocean, with its ceaseless heaving,
and its deep cerulean waves, and the golden and
crimsoned heavens at the rising and setting sun;
look at nature, even in her decay, in the variegat-
ed glories of autumn, or reposing under her jew-
elled mantle in the death of winter, look at every
thing in its individual form, or in its combinations,
and even in objects which seem offensive or loath-
some, or terrific,—all, all, is flooded with beauty.
I have stood hour after hour, gazing at the mighty
Niagara; and while I beheld in its tremendous
movement, an image of the Divine Power, and in
its ceaseless flow, a symbol of the Divine Eterni-
ty, yet in its deep torrent of living green, its glitter-
ing tresses, of a whiteness which the drifted
snow does not surpass, and in the dazzling iris,
spanning its troubled and foaming abyss, and
girding as it were, the lion's neck with a creature
of brilliant, beauty, ineffable beauty, pervaded
and triumphed over the whole; and there, of all
other places on earth, seemed to have fixed his
throne and to demand universal homage

Non-Resident Lands in Michigan.

THE undersigned respectfully announces to the public, that he has opened an office in this city for the specific sale of non-resident lands, now or hereafter to become due, in any of the Counties of this State and he will visit himself, or by a trusted party, the Counties, to obtain all necessary information upon the subject.

Persons wishing taxes paid in any of the Counties in Michigan, and forwarding to the undersigned the necessary amount of tax, and the proper order, together with an acknowledgment of their lands, may rest assured that their interests shall be scrupulously attended to.

His charges will be all times reasonable, and proportionate to the services rendered.

The undersigned will endeavor to make himself thoroughly conversant with the value of lands in every part of the State, and he may be enabled to give information to all enquirers, and if desired, will undertake the sale of the same. He wishes to meet respectfully to refer as to character, and capacity, to reclaim the pledges above given, to the undersigned.

J. L. WHITING.

Detroit, March 1, 1840.

I think such an office as is proposed by Dr. J. L. Whiting, highly necessary for the convenience of the community, and that he is exceedingly well qualified by long residence in Michigan, his personal knowledge of the country, strict integrity, and domestic business habits, for the discharge of the proposed Agency.

C. C. TROWBRIDGE.

I concur fully in the sentiments and expressions expressed in the above notice of Dr. J. L. Whiting, and am, therefore, in full

W. M. WOODBROOK, Governor of Michigan.

I have been acquainted with Dr. J. L. Whiting for many years, and fully concur in the views above expressed by Mr. Trowbridge.

Dr. J. L. Whiting is in my judgment fully competent to discharge the duties of the proposed Agency, and I cheerfully recommend him to the public.

From long and intimate acquaintance with Dr. J. L. Whiting, I am happy to testify my full concurrence in the above statements.

THOMAS ROWLAND, Secretary of State.

Jan. 10th, Detroit, March 1, 1840.

Having long known Dr. J. L. Whiting, I most cheerfully concur in the above sentiments, and would further endeavor to him any facilities in the Land Office may afford in all the objects of his advertisement.

J. REARSELY, Receiver.

I have been intimately acquainted with Dr. J. L. Whiting for several years, and fully concur in the sentiments above expressed, in relation to him.

D. PITCHER, Mayor of Detroit.

Such an office as Dr. Whiting proposes, will be of great utility and convenience to non-resident lands, and I am happy to assure the public, that he is every way qualified, and can be fully relied on.

ROBERT STUART, Treasurer of Michigan.

Having known Dr. Whiting for many years, I fully concur in the above.

D. GOODMAN, Attorney.

To the above ample testimonials in reference to the capacity, integrity and integrity of Dr. Whiting, I take pleasure in adding my full and cordial concurrence, and heartily concur in the proposal of the proposed Agency.

JOHN A. WELLS, Cashier Farmers & Merchants' Bank.

MULBERRY TREES ON SHARES.

AS there is every prospect that the demand for the finest kinds of Mulberry for silks will be greater next spring than the supply, I now offer to furnish 200,000 very fine trees of the Mour, Elton, Fremont, and Marcella varieties to be cultivated on equal shares, one half the trees to be produced therefrom to be delivered in my order in the spring of 1841. The expense of packing and transportation to be paid by the person ordering them. The packing and delivery to a vessel or Transportation Line, will cost \$2 per hundred, and any person desirous to contract as above, will, on returning \$2 per hundred, receive the trees, with full information with the number he may desire.

WM. R. PRING, Livingston Butte garden and Nursery, Elm Hill, N. Y. April 15th, 1840.

ATKINSON FEMALE SEMINARY.

MRS. ATKINSON, having removed to the city, is prepared to receive a few more scholars, who are admitted as boarders—competent teachers are provided and all branches of study pursued to give a finished education. Parents may rest assured that every attention will be paid to the moral and intellectual improvement of the pupils.

Terms are forty dollars per quarter of 12 weeks, including tuition, board, washing, fuel and light, payable in advance. The following branches are taught: Latin, Greek, French, English, Geography, Greek, Latin, Music and Drawing. Seminary on Canal's east.

May 1st, 1840.

BEEBEE'S STRAW CARRIER.

THE carrier has in use and holds the right in his Patent Straw Carrier, for the counties of Genesee, Livingston, Ontario, Wayne and Orleans, in the State of New York, and in the counties of Huron, Sandusky, and Seneca, in the State of Ohio, all persons wishing the above carrier, may be supplied in Orleans Co., N. Y., by Philip Beman of Caledonia in Genesee Co., N. Y., by Lemuel Condit at Riga Centre, and in the counties of Ontario and Livingston by George C. M. Farn of Seneca, Monroe Co. Those wishing the above machines in any other part of the United States, will please apply to the undersigned. All persons wishing the above machines before the first of October next, will be supplied by rail-road. Carriage and state rights on warehouse terms.

LEAH BEEBEE, Riga, Monroe Co., N. Y.

April 1st, 1840.

RECOMMENDATION FOR THE PATENT STRAW CARRIER.

The said carrier having been used by the Fish Beebe's Patent Straw Carrier, I believe it to be much more as a labor saving machine, it performs the work of separating the straw and chaff from Wheat, Oats and Barley, with the least amount of noise and at cheap rates, and is simple and cheap. Possessing, as we conceive, all those qualities in an eminent degree, we cheerfully recommend it to the public.

Wm. Wakefield, R. H. Moore, Jr., Wheatland, Wm. Smith, Cambridge, Wm. Garstin, Samuel Cook, Wheatland, George Sheffer, Jan. 4th, 1840, William Reed.

The Imported Horse, Alfred.

NO. 6. { HENRY COLMAN, *Editor.*

MADE AT THE ROCHESTER COLLEGIATE INSTITUTE BY
L. WETHERELL, MAY, 1842.

Mean temperature of April,	1812,	45.85	degrees
"	"	1841,	39.87 "
"	"	1849,	47.80 "

Vegetation was considered very forward April 25th.

* This patriotic statesman has reduced his own rent roll 20 per cent, in order to enable his tenants to live under the reduction in the duties on imported provisions.

As to the error respecting the amount of Silk in Massachusetts, I have already written an explanation to the editor of the Silk Agriculturalist, who, believing from the context of my Report there must be a mistake, was so kind as to write me and inquire respect-

ing it. The error arose in reducing the different statements of accounts collected, some in cocoons and some in silk, the latter of which had to be increased, and the time of printing my Report did not allow me to review the computation of the assistant.

As to the wheat crop of Massachusetts, which I have estimated in 1841 at 189,571 bushels, I remark there is only 31,648 bushels more than that of 1839, on which the census of 1840 was taken. The census was taken, you are aware, by persons on oath, and is high authority—the gain, about 16 per cent. in two years, is not incredible, allowing for the increase of population. The bounty too does not apply to any fractions under 15 bushels.

As to the quantity of green stalk per acre, at which you marvel so much, you will find that 5 lbs. per square foot is not an over estimate for the richest land well prepared, in the latitude where the experiment was made, and where the stalk grows much higher than at the north. If you have seen the Baden corn grow at the north, you may well imagine, that if, as you admit, herds grass has produced, when green, 49,837 lbs. per acre, such corn sowed broad-cast, say 5 bushels per acre, and permitted to grow as thick as it will flourish, may yield a crop five times as great as that of the grass. You must not of course expect so much in the short summers at the north, but I carefully weighed the produce of two feet square or four square feet of ground of the stoutest in my field, and the aggregate was 20 pounds, equal to 5 pounds per foot.

The march of improvement is onward, and when you peruse the process of converting pork or lard into oil and stearine, and examine more fully the data on which the statistics are founded, you will be less sceptical as to the early period when you may "throw up your hat."

While the guardians of the Press should sedulously avoid imposing on credulity, it must not be forgotten that it requires strong encouragement and great faith to induce the travellers in a beaten path to take a different one. I will not say that your remarks will have the effect to stifle effort, though the tenor of the remarks is supposed by some to cast an air of ridicule on the experiments mentioned.

Wishing you success in your zealous endeavors in the cause of agriculture, I remain

Yours respectfully,

H. L. ELLSWORTH.

HENRY COLMAN, Rochester, N. Y.

Editorial remarks on the above.

We have much pleasure in presenting to our readers the foregoing letter of the Commissioner of Patents in reply to our strictures upon his late Report. Mr. Ellsworth cannot, we are persuaded, for a moment distrust the high personal respect, which we have for years entertained towards him, and the grateful sentiments with which we have regarded his zealous, disinterested and enlightened efforts for the advancement of an improved Husbandry. We shall add on this subject nothing to what we have already said. We disavow, therefore, every thing personal from the case, and look at the Commissioner's Report as we would look at any other public document of the Government. As such we hold it open, and deem it well for the public and the Department itself, that it should be subjected to fair and honorable criticism. If our remarks have been of a different character, no one will regret it more than ourselves. At present, however, so unconscious are we of any intention of that kind, that we do not see it.

We write these remarks five hundred miles from home, and therefore are unable to recur to Mr. Webb's statement of his process of extracting sugar from corn stalks given in the valuable pamphlet published by the National Agricultural Society, and which will ap-

pear in this number of the Farmer.* We do not impugn any of the statements there made; but we confess we shall wait with some impatience to see those anticipations verified.

The production of 108 tons of corn fodder to an acre is still a matter of surprise to us; not that we doubt Mr. Ellsworth's testimony, but because the amount is so very large. The editor of the New England Farmer has kindly stated to us that the crop of 37 tons, to which he referred, was produced on the place of Daniel Putnam of Danvers, one of the best farmers in Massachusetts, and that in this case three square rods were cut and weighed, in order to determine the amount of the whole crop. He states likewise, that in referring to a product of more than one hundred tons to an acre, he rested on the statement of Mr. Ellsworth. Mr. E.'s result was obtained by measuring and weighing the product of four square feet. In both cases the seed was sown broad-cast. There is always an uncertainty or liability to mistake where the whole crop is determined by the measurement of such small parcels. Here for example is a difference of 71 tons upon an acre between the results obtained by two gentlemen of equal credibility and undoubted truth. Mr. Ellsworth may account for this difference in the different kinds of corn sown, the gourd-seed at the South, the flint corn at the North, the stalks and foliage of the former being much more abundant than the latter. But we understood Mr. Putnam to say that the gourd-seed or southern corn was sown in Danvers, in the case referred to. The difference in latitude or climate would undoubtedly produce a difference in the amount in favor of the South, but to what extent it is not possible for us to determine. When we admitted that Herds Grass, cut green, had produced at the rate of 49,837 lbs. to the acre, we did it upon authority, which is deemed sufficient; but, as will be seen from the form of expression used, not as a matter which ever came within our personal cognizance or experience. But again, upon the supposition that by Mr. Ellsworth's mode of planting, 108 tons of green corn fodder can be produced, it will be seen that the growing crop must cover entirely the whole ground, whereas, on Mr. Webb's plan at least a third of the ground must be left in the open spaces necessary for the cultivation of the crop and for access in order to pluck the ears before their maturity. The product of corn sowed for fodder is undoubtedly much beyond what most persons would apprehend; but how much may be obtained is a matter of such easy ascertainment by every farmer, that we may best leave it to every farmer to determine for himself.

Our remarks on the amount of wheat given in Mr. Ellsworth's statistical tables, as produced in Massachusetts in 1841-2, were designed to show mainly how little reliance can be placed upon statistics of that sort when obtained by estimate, not to say conjecture. An error of 31,000 in a sum of 189,000, does not seem to us a small error; and if proper information had been given to the Commissioner, we believe that the return of wheat produced in Massachusetts in 1841, instead of being increased over that of 1839, would have been diminished, as the cultivation has evidently fallen off since that time. Mr. E. says that his tables give only 31,648 bushels more than was given in 1839, on which the census of 1840 was based. Now we have no disposition to be hypocritical in this case; but there appears some reason to suppose in this instance, that in making out the return for 1841 no reference was had to the returns by the census. The returns by the census for 1840, gave 158,923½ bushels. The returns made to the Massachusetts Secretary's Office in 1838-9, with a view to obtain the bounty, were 108,570½ bushels. The return given by

estimate in the Commissioner's tables are 189,571. Now to any nothing of the extraordinary accuracy of estimating or guessing in such case to a single bushel the whole crop of wheat raised in the state, yet the two numbers, 108,570½ and 189,571, look so nearly alike that we can hardly refrain from the conclusion that the latter is somehow immediately related to the former; and that therefore the clerk, who made out this return in Mr. E.'s tables, did not as Mr. E.'s letter would seem to imply, make it out from the United States Census, but from the return made to the Massachusetts Secretary's office, and wholly as matter of arbitrary conjecture.

The extraordinary error in the tables as to the amount of Silk Cocoons produced in Massachusetts in 1841-2, of 198,432 lbs. instead of 27,219 lbs., Mr. E. accounts for partly in the want of time to review the computation of his assistant. Clerical errors in all numerical calculations are very liable to occur even with the most exact; but this was so large that we can only advise Mr. E.'s assistant to take shelter under the distinguished example of the Secretary of the U. S. Treasury, who we believe in his reports to Congress only made a trifling mistake of one or two millions of dollars. Mr. E. would seem to suggest, that we should have followed the example of the Editor of the Silk Agriculturist, who kindly wrote to inquire if this statement of silk product were not an error, and to whom Mr. E. has furnished an explanation. And this report been a private or personal matter with Mr. E., we should certainly have adopted the same course; but in respect to a public document, published by order of Congress, it might be considered intrusive if not impertinent, if gentlemen requiring explanations or information in such cases, should write private letters to the different heads of departments in order to obtain them.

But our remarks had, we trust Mr. E. will do us the justice to believe, a much higher aim than the correction of a mere clerical error. We deem statistical knowledge of great importance, and Mr. E.'s desire to furnish it in the highest measure honorable to him; but in order to be valuable, statistical statements should rest upon perfectly authentic data; and we wish that Congress should see the necessity of making ample provision for obtaining and publishing them; and not suffer them to be given upon mere vague estimates, nor impose so much duty upon a public officer that he should not have time to review and correct them, nor especially that returns such as those of hemp and flax should be so jumbled together, (the fault of those who took the census) that it could not be determined how much of flax or how much of hemp was raised, nor whether the figures in which the returns are made mean tons of hemp or pounds of flax.

In Mr. E.'s extraordinary anticipations respecting the production of silk, we confess we have no sympathy. We would, as we have done, ardently, constantly, and indefinitely, through good report and evil report, encourage its production as one of the most important agricultural interests of the country; but the calculation of one person in every hundred of the inhabitants of the United States producing annually a hundred pounds of silk, and the product being 18,000,000 pounds, worth 90,000,000 dollars, seems to us pure romance. If "some persons" suppose our remarks in this case adapted to "cast an air of ridicule" on the subject, we apprehend that this "air" belongs to the thing itself and not to the spirit or tenor of our humble observations. The public would suffer far more from encouraging such expectations than from showing their delusiveness. The cause of silk culture has been already put back a quarter of a century by the extravagance of the statements and calculations of those, who called themselves its most ardent friends, and who, with the exception of a few

* See last month's Farmer.

honest and honorable men, were mere gamblers in nursery trees and speculators upon the public credulity. So it is likely to be in respect to other agricultural improvements. We must not expect to reach the goal at which centuries have aimed by a single leap. The public mind by great pain-taking has just come to that healthy state in which it begins to take an interest and find a rich pleasure in agricultural inquiry; and the ignorant are ceasing to sneer at book-farming and have become willing to read and to listen. They need now to be nourished by the calm and reasonable statement of facts and experiments; but to approach them now with mere discursive calculations, and promises so extravagant that they transcend all reasonable expectations and experience, will only create disappointment and disgust, and essentially injure the great cause, which many of the best and most intelligent minds of the community have so much at heart.

There is a great deal of valuable matter in the report besides that to which we have referred, of which we shall hereafter avail ourselves.

To Correspondents.—Post Office and Postage.

We do not agree with our respected friend from Cayuga, that the decision of the Post Master is wrong in regard to endorsing newspapers. If "A. B.'s compliments to C. D." mean nothing, then the writer cannot complain that he is not allowed to put them on the paper. But they mean a good deal; they signify the good will of the person who writes; his kind remembrance; that the paper comes from him; and would be understood generally to imply that the writer was well, and invited attention particularly to something in the paper. If it was lawful to put so much, why should it not be lawful to put compliments also, to E. F., and G. H., and so on, inserting as many tender messages as you please to the mistress of the household, and so through all the aunts and cousins down to Boots and Betty, the scrub. The mail is designed for the general accommodation and comfort; for the aid of business and commerce, the diffusion of intelligence, and the maintenance of social intercourse, the great charm of life. Every man or woman, therefore, who in any respect whatever avails himself of its advantages, should be willing to pay for those advantages, and not attempt to evade their obligation by any sort of skulking whatever.

Then we think it the imperative duty of the Government to render this form of communication as rapid, as certain, as diffusive, and as cheap as possible. We therefore protest against the late proposition of the Post Master General to increase the 18 3/4 cent postage to 20 cents. If the present extension of mail conveyances and facilities are not sufficient for the demands of the country, then let the Government make them so. If the income of the office is not sufficient to meet the expenses, supply it from other sources, if we are ever likely again to have any thing to give. Let the public accommodation in this matter be the first object. The rates of postage are already much too high. Reduce your 25 cent postage to 12 1/2 and your 18 3/4 to 10 cents, and your 12 1/2 and all others to 5 cents, and there can be very little doubt that the revenue of the Post Office would be greatly increased. Then put an entire stop to the franking privilege excepting in the Great Departments of Government, and the health of this great concern now complained of as "in a poor way and very much inclined to consumption," would be speedily restored. Such a change would greatly multiply the epistolary correspondence of the country; and the unfortunate individuals, who are just taking their departure at the great points in steamboats and cars, would not be dunned with, "Sir, I was too late for the mail, (nine times out of ten a lie) will you take a letter?" and then find themselves regularly transformed into U. S. Mail bags. Twenty and thirty letters, as we know by experience, are not an uncommon num-

ber to be offered to one individual, because the writers "unfortunately missed the mail."

We believe as much as we live, if all postages of single letters were reduced to ten or even six cents, and double letters to fifteen cents and five for every additional sheet for any distance, and the payment of this postage always required when the letter is deposited or rather stamps purchased, and the franking privilege abolished or much limited, the revenue of the Department would be essentially increased, and sufficient for the purposes of the country.

Post Office and Postage.

[In a letter from Cayuga County.]

How could we live if the mail was stopped, and the post office closed? Yet I well remember when in a populous neighborhood of another state, scarcely any person thought of visiting the post office, if such a place was even known. "How did you get letters?" By private conveyance. "And your newspapers?" From the printing office in the city, at the distance of twenty-five miles.

Within the present century, *Scipio P. O.* was kept in the village of Aurora. It was called so, because it was the only office of the kind in that old town, though the population even at that time was great. When wheat was carried to Albany in sleighs at a cost of 75 cents a bushel, money was hard to get, and postoffice bills not so easily paid as at present. Letters and papers were luxuries that but few persons could well afford, to much extent. Now there are seven post offices within the limits of that old town, on the two stage roads between Auburn and Ithaca, besides four more at least which are kept in the eastern parts of the district.

These notes are intended to show the general and increasing interest that is felt in the Post Office Department, an establishment which necessarily requires millions for its support. This revenue is derived chiefly from a tax upon letters. With a liberality adapted to republican institutions, newspapers weighing several times as much as a letter that is charged twenty-five cents, are carried throughout the whole length of the United States for one cent and a half—so we may all be politicians.

This liberality however, is not met in all cases in a proper spirit by our citizens. Under the shelter of a newspaper, many contrive to send intelligence which ought to be subject to letter postage, and which is subject to it when found out. Honorable, upright minds however, that have reflected on the matter, will refrain from such practices; and be willing to bear their proper proportion of the burdens imposed by the Government.

The law of Congress requires the postmaster when any thing is written on a newspaper, which amounts to a memorandum, to charge letter postage for it, and if the receiver will not pay it, the paper is sent back, and the writer subjected to a fine of five dollars. All laws of this nature, leave much discretionary power with the Heads of Departments, and it is very desirable that they should receive a liberal interpretation. It is very desirable that whenever a citizen is mulcted, that both he and the community should be satisfied that the intent and meaning of the law, as well as the public welfare, required it to be done.

When a person writes a letter on a newspaper, or transfers a letter already written to a newspaper, by dotting or underscoring a printed word for each written word, as they occur in succession,—it is clearly an attempt to evade the law, and to wrong the Department of its just dues. No candid person can say a word in defence of such practice, and it ought to be discountenanced by every good citizen. When the penalty of the law overtakes such offenders after due warning, it is a just punishment; and the hands of the postmaster ought to be strengthened to perform the duty.

In my judgment however, it is a different affair when

the Post Master General construes a memorandum to mean any thing that is written on a newspaper besides the direction. For instance: If a person sends a newspaper with his name on it, to indicate whence it came, ought it to be considered an offence? But I will go one step further: suppose he writes on the margin "A. B.'s compliments to C. D.," and no more, would a liberal construction of the law make it an offence? It is equivalent to the simplest act of recognition when we meet a passenger in the road. Not a word is spoken in one case, nor an additional word in the other. It wrongs the Department out of nothing, for no man would write a letter for the purpose of saying no more than that. He communicates no more intelligence than the man who silently touches his hat.

But the Post Master General has the power to say that a compliment so written and so sent shall subject the receiver to letter postage, or the writer to a fine of five dollars; and out of

'Respect for his high place!'

I would on no occasion offend him in this particular; but it is bad policy for an officer to strain his authority.

Home League—Protective Tariff.

Those who take but a superficial view of trade and its ramifications, are very apt to hail a protective tariff as the only panacea to bring back a healthy, prosperous trade to the nation.

My experience goes to prove that the pecuniary ills we now suffer, are by no means chargeable to a diminution of tariff under the compromise act, but rather to the abuse of the credit system. Now my agricultural friends, I appeal to your experience in relation to the credit system; have you not seen at a farmer's vendue, cows, horses, oxen, and all implements of husbandry, sold 50 per cent. higher on a credit of 12 months, than they would bring in cash? The same extra price for credit will apply to all our imported goods. When we can pay England with paper promises, we always buy too much, hence the outcry for a tariff to stop the overtrade; but when we have to pay specie for goods, the check to excessive importation is sufficient, without an extra tariff.

As long as England would take our State Stocks and United States Bank Stocks at par, our banks discounted freely and our imports were excessive; but now when these paper credits have exploded, and we must pay specie for the excess of our imports over our exports, the necessity of a protective tariff is done away.

If I was asked what was the leading cause of the present money pressure, I should say it was the depreciation in State Stocks, they no longer being available in England at any price. Six millions of specie had to go forward last fall to pay for goods, which at other times had been paid for in scrip; this brought our specie paying banks to their marrow bones. Had England continued to take scrip, there would have been no present panic, but our debt to her would soon have been so large, that our export of cotton and tobacco to Great Britain, would hardly have paid the interest of it. If I mistake not, this failure of our credit is a better protection against British manufactures, than 50 per cent. increase in our tariff. Hence my doctrine is, let us have a tariff for revenue only, but let it be imposed with such discrimination as will protect those branches of our manufactures that most need it, while it promotes free trade with those nations who take exclusively the products of our industry in payment for their productions.

To say the least of the evil of a protective tariff, its tendency to inflation is inevitable; ruinous competition and reaction must follow—the extravagant habits it entails upon community palsies all the humble charities of social life, and brings economy and self-denial to shame.

OLD HUMPHREY OF THE GENESSEE.

Candles from Castor Oil.

[Extract of a letter from Hillsboro', Illinois.]

"I wish it was in my power to give you some information in regard to the manufacture of Candles from Castor Oil, which I notice you ask for in a late Farmer. I have made many inquiries about them and learn on good authority, that they burn a little longer than sperm candles, give quite as good a light, and are harder; also that when the beans are worth one dollar per bushel, the candles can be furnished at 25 cents per pound. Our farmers are quite content with a dollar per bushel for the beans, which is the price they have borne for a number of years. Although the last season was so dry, beans about us produced well, giving as much as twenty bushels from an acre; and as they were the only article which brought money readily, every one was on tip-toe for raising them. One man, I heard of, who had never raised one in his life, or even seen them raised, was going to plant a hundred and fifty acres with them. The price of oil being reduced from one dollar to twenty five cents per gallon, has very much allayed this bean fever which began to rage."

This certainly promises to be a profitable article of cultivation. The beans are planted in rows, and require only a clean cultivation; but we do not feel sufficiently acquainted with the culture to give specific directions. We rejoice in every new production of articles of use, necessity, or comfort. True independence consists in the power of supplying our own wants from our own resources; and the best of all rules in domestic economy is for the farmer to obtain from his own farm, every article of necessity, which the farm can be made to yield. With the encouraging prospect of oil and candles from corn, lord, and the castor bean, there is some reasonable chance that the sovereignty of the ocean may be again surrendered to the king of fishes.

Culture of the Cucumber.

We know nothing of the advantage or utility of the method of cultivating Cucumbers recommended below, but give it on the credit of our correspondent. On a small scale, if effectual, it is an easy way of getting rid of the enemy, to send them out with perfumes. An old and eminent physician in Boston used to recommend as the best preparation of cucumbers for the table, to cut them in thin slices, salt and pepper them well, apply a sufficient quantity of the best wine vinegar, and then throw them out of the window. We know the favoritism with which many persons regard them, but we never see a plate of them on the table without at least thinking of the Cholera. We have known some persons who preferred to eat them after they became, as they termed it, dead ripe, and as yellow as a custard pudding. In this way they were not quite as likely to irritate the teeth as crackling walnuts.

Mr. Esprit—I wish you to publish the following, written by Mr. James L. Enos, if you have room in your valuable paper.

O. O. O.

Culture of the Cucumber, by James L. Enos.

"The best and most sure way to raise cucumbers, is to dig holes in the ground about one foot in depth at the distance required for the hills, then fill these holes nearly full of leached ashes; cover them over with about one inch of fine light earth, sow on your seed, (but not until your land is dry and your seed well soaked in warm water or milk,) and cover it over lightly with fine dirt.

"The ashes will prevent the worms from eating the seeds or the young vines. As soon as the leaves begin to start, and the striped bug begins to eat the leaves, go and pick a handful of Tansy and lay two or three spears around in each hill, they will soon move off for some other place and will not trouble you any more. Hoe them three or four times, as necessity requires.

Try this manner of procedure and reap your rich reward."

East China, Wyoming Co., May 3, 1842.

Western Manners.

Extract from a private letter from a friend at the West.

"We are very much pleased with our nearest neighbor, Mr. ———. They visit us often and treat us with much kindness and attention. His family consists of eight daughters, the oldest 19 years of age, good, substantial girls, who ask no odds in knitting, spinning, weaving, milking and housework. When planting comes, they take the field, armed with their hoes, and go right ahead without any parol or shoes."

There's for you! Look here, young men! we were about to say; but the truth is that there is scarcely one young man in twenty among us, a parcel of dandified, sugar-smoking, watch-chain-sporting, whiskered and mustachioed monkeys, there is hardly one in twenty that has even the shadow of a claim to such a blessing from Heaven as one of these eight girls must be to any industrious, clever fellow, whose only capital is his hands, and who wishes to get an honest living by his own labor. Such a wife would be a fortune in itself; and such a man had better have one such wife than to marry a whole boarding school of your nanby pambly, silky-milky trash, that too often passes under the name of accomplished; poor irresponsible butterlies! who pretend to faint at the sight of a cow as though it were some foreign wild beast escaped from a travelling menagerie, and, dear souls! don't know whether the milk comes out of the udder or the horns. What are such women good for, excepting to put in a glass case, like a beautiful piece of alabaster statuary, to ornament a mantel piece or a china closet; we mean so far as concerns getting a living, taking care of a family, or the honest accumulation of wealth. We acknowledge, old and new as we have grown, that some of them are as pretty as the sweet fairy humming birds, the embodiment of every thing that is beautiful and poetic in form and motion, that haunt the flower-garden at the close of the day, receding and imparting an exquisite delight; but to what substantial use can such things be put? Now we don't object to accomplishments, the most intellectual and the most polite accomplishments; but we maintain that there is no incompatibility between physical labor and intellectual labor; that the exertion and increase of the physical strengthens the intellectual powers; that a woman ought to understand as well the use of her hands and her limbs as of her mind; that no human being, unless in case of disease or deformity, is justified in living without some useful labor; that while we should feel as adverse as possible to subjecting women to any severe and degrading toil, we think that there are many kinds of out-door labor on a farm, which women might perform in company with their fathers and brethren, with signal advantage and improvement to their health and persons, provided only that they will lay aside their iron armor. In this age so preeminent for its trippery and foppiness in education and manners, it is quite a relief to find one sensible man, who knows how to bring them up, filled with eight daughters to bring up. We have heard much of late years of the want of girls at the West. But if this account is at all a fair indication of the state of things there, the demand will soon be supplied by the home growth; and if our own girls in these high tariff times will allow us to say it, we must either produce a better article among ourselves, or be permitted to import from the West duty free. But we begin to be alarmed at our own tenacity in so much as hinting these things; and as the almanac makers say, running down a whole page, we shall "look out for a storm about these days."

The passions are good servants but terrible masters.

Western Adjuncts and Contrasts.

Extracts from a letter from the West.—"I wish you could spend a month with us now. I don't think our place would seem so foreign and out of humanity's reach as it did when you was here; travelling will soon be so cheap that you can bring ——— with you. (Heaven forbid that we should ever venture again without our baggage!) Our nearest neighbor has large orchards of apple, peach and cherry trees. I put four acres in wheat last fall, which is now looking finely; this spring I have sowed five acres with oats; and just finished eight acres for corn and three for castor oil beans; if the weather continues favorable, I intend to plant ten acres more in corn."

This is certainly all bright and beautiful, and we are sorry that there should be a cloud even so big as a man's hand in this western sky but what earthly draught is unmixed; so we read farther on,

"C ——— has not had any fever and ague for a long time and seems to think he has got rid of it. Mr. H ——— has had the fever and ague pretty bad this spring—'he is better now'—&c. &c.

We shall add nothing about the currency or money ague, which has been upon them for some time; and in respect to which they are, we believe, past the shaking and have actually become stiff. When 45 cents per bushel, Pork 1½ cent per pound, Corn 10 cents per bushel, and no money; so as *en Ohio* farmer informed us it required only eighty bushels of corn to buy one pair of boots. But then all such luxuries may be dispensed with, as there are no stones upon the prairies; and they are every where carpeted with flowers.

Sale of Mr. Weddle's Stock, on the 29th and 30th of March.

We were prevented from attending this sale, but a friend has furnished us the following account of the prices and purchasers.

Cow Gazelle, 4 years old, sired by Rover, to John B. Dill, Auburn, \$500.

Cow Hebe, 2 years old, by American Comet, J. M. Sherwood, Auburn, \$500.

Lucilla, 1 year old, by American Comet, to Calvin Ward, Bristol, \$260.

Matilda, 1 year old, to Geo. Hentig, Geneva, \$100.

Bull American Comet, to Geo. Hentig, Geneva, \$325.

About thirty Cows, half and three quarter blooded, sold from 25 to 55 dollars each.

About twenty-five Heifers, two years old, sold for from 20 to 30 dollars each.

About thirty Calves and Yearlings, with other young stock of various grades, sold at an average of about 15 dollars each.

Stud Colt, 3 years old, sired by imported Turk, to J. Clark, \$500.

Stud Colt, 3 years old, sired by imported Turk, to T. Weddle, \$325.

Stud Colt, 3 years old, sired by imported Turk, to H. Paddock, \$225.

1 Mare, 10 years old, to G. Ferdon, \$120.

1 do. 6 years old, to G. S. Rappley, \$110.

1 do. 4 years old, by Alford, to G. S. Rappley, \$152.50.

1 Span of Mares, 6 and 8 years old, to G. Hentig, \$312.

About 30 Leicester Bucks and Ewes, sold for from 5 to 20 dollars each.

Some fine flocks of half and three quarters blooded Ewes and Wethers, brought from \$3 to \$3.50 each.

Shipment of Improved Stock to Canada.

The steamboat America, on the 16th ult., took on board at this place a fine three year old stud colt, bred by Thos. Weddle, and sired by his imported horse Turk. Also, a very fine Durham bull, 2 years old, and a Durham calf, all purchased of Mr. Weddle, for the Northumberland Agricultural Society, by two gentlemen sent over for that purpose.

To Correspondents.--Bee Management.

W. S. T. on the Management of Bees invites the attention of our readers to a small but important subject, and one intimately connected with household economy. We agree with him in his estimation of the value of the Vermont Patent Hive, by John M. Weeks, and we know no better book of the size, indeed none so good, as that of Mr. Weeks on the whole management of Bees, two or three editions of which have been published. We have on hand a manuscript communication from Mr. Weeks on the subject of bees, and one from another friend J. V. C. S., which we shall presently give to our readers. John Sholl, of the city of New York, a member of the Society of Friends, is likewise the inventor of a Hive, made from a flour barrel, and which may be suspended any where; of an excellent construction, furnishing facilities for obtaining the surplus honey at pleasure, preserving an equable temperature in the hive both winter and summer, and almost absolutely effectual against the entrance of the Miller. We design to have in our office at Rochester, for the gratification of those interested, a model of Weeks' and Sholl's Hives. Thatcher's and Griffith's Hives are likewise good models; and all go upon the principle of not "muzzling the ox that treadeth out the corn," and abandon the old atrocious system of Algerine Piracy, first to murder and then rob.

An excellent Hive, Beard's, has likewise been invented in Maine, which we know only from the recommendation of others, but which we mean to inspect the first opportunity. We learnt the fact of a single individual having sold the summer before the last to the value of more than one thousand dollars in Honey and Bees. This is more than many farmers, even in Western New York, obtain for their year's crop of wheat. We found in Vermont last summer, on one farm a stock of one hundred and twenty-five hives. This bee-master gave a decided preference to Weeks' Patent Hive over every other, that he had seen.

Nutt's English Hive is a beautiful erection; highly ornamental in a garden or orchard; and combining in an eminent degree all the desirable properties. The Bee Houses, as they are called, and the keeping of bees in garrets, have generally failed after two or three years, some through the ravages of the moth and some for other reasons.

Management of Bees.

MR. COLMAN--Having been a reader of the New Genesee Farmer for about two years past, I have as yet seen very little written upon the management of the honey bee. Feeling an interest in this subject, I send you a few brief hints as to the best mode of protecting the honey bee from the moths, that they may not destroy their useful works. The farmers in this vicinity, at an early day, kept bees to good success. Of late years the millers have become so troublesome that it is almost impossible to keep bees. More care and attention are required now at the present day to keep bees, than when the country was new. A few years ago, many farmers in this section tried, by way of experiment, small houses for the honey bee; but this was not an effectual protection, the moth soon got possession of the building and destroyed them. The common hive is better than such buildings if set in proper places and taken good care of. The best hive in use, is, in my opinion, the patent hive invented by John M. Weeks of Vermont. In order for us to keep bees as formerly, we must obtain this new patent hive, and give our leisure moments to the care of them. The moths and millers are more prevalent now than formerly. It is therefore highly desirable to obtain a hive that will be a preventive against the moth. With proper exertions we can, in my opinion, keep bees now as well as formerly. The patent hive

is preferred to any other for this reason, that we can obtain the sweets of life at any time without killing the bees. There seems to be great cruelty in killing such industrious creatures. The patent hive is not much used in this section, but the time is not far distant when it will be the only hive in use. As soon as farmers make a trial of them, they will abandon the common hive. The common hive will answer very well in a new country, where the moths are not so prevalent. The great difficulty in keeping bees in this country, is in the moths and millers obtaining possession of the hive, and thus destroying those ingenious fabrications which are beyond the power and wisdom of man to construct. I shall continue my views upon this subject hereafter.

South Venice, 1842.

W. S. T.

For the New Genesee Farmer.

MR. COLMAN--If there are any evils which require philosophy to support them, we think those of an editor among the number. And if question asking is to be ranked among these evils, we think as the thirst of knowledge is being more and more excited in the feverish mind of man, these evils must continue to increase until the fountains of knowledge are widely opened. There is no way to open these fountains only for every one to put forth a helping hand. We must have our Davids in the field as well as our Goliaths; and if the stature and strength of the former falls far short of those of the latter, the good will manifested, will in some measure compensate for the deed.

We have noticed with some sympathy, the dilemma in which you are placed by the catechising part of your subscribers. Why sir, if you had as many pens as you have fingers and should keep them in constant practice, you could not stop the clamors of this enquiring truth seeking age. Prompted by these reflections, I have sent you my mite, hoping in a particular or two to relieve you from embarrassment in which you are placed. In answer then, to the enquiry of your Connecticut River correspondent, respecting bees, permit me to reply.

That the best way to keep bees through the winter, is to keep them cool, dry and dark. This may be accomplished in various ways. We have buried them with good success. But the season must favor this operation, or it will not succeed so well. In open winters like the past, we should not approve of this course, for by the frequent thawings of the earth, they are liable to get wet, mould and die. The best success attends burying, when the ground freezes immediately over the hive and remains frozen until Spring. In winters like the past, keep them in a cool, dark room, where the storms will be entirely excluded from them. In such places they will be likely to remain dormant, which is much in their favor.

Summer management. Salt your bees as often as once a week; if oftener better. Water them at some pure stream every day. Now friend of Connecticut River, we are not boxing you. Bees entail. Its qualities are also anti-moth. If a little remains around your hives, it will help you to guard against these pestiferous animals. Though your bees may sometimes be rather obstinate about driving to water, yet rest assured, that if you locate your apiary near a good fresh stream or pool, as you should do, they will soon find the way to it themselves, after which, you will have no trouble of driving, for when found, they know and appreciate the excellency of its cooling and cleansing qualities as fully as the most fastidious of our own species. Let their hives, also, be in a cool and quiet place, not so near the highway as to endanger the horses of passers by on a sultry day, for such a rencontre would not only be fraught with dangerous consequences to your neighbor and his beast, but to themselves also. Allow the visitors at your place

to ask such questions as they please with regard to their prosperity, but do not allow them to run among your hives, lifting up this and drumming on that, for the little warriors will be aroused if you do, and very likely punish you for "allowing liberties to be taken with them." Keep cool when you go among them; they like system, and to have every thing done at the right time and in a right way.

At swarming time, in particular use discretion, and do not be in a hurry. If you wish to blow tin horns or drum on old pans for your own amusement when they are rising, you can do it, but they will pay but little regard to such ceremonies. The Shakers in New Lebanon, who are the best bee managers we know of, have nothing to do with this flummery. They set a shaker hat on a pole some four or five feet high, (probably the hat of their chief attendant, which they will know as quick as a dog will the back of his master,) and the swarms frequently alight upon it. These people have the confidence of their bee community so much that they handle them with as much indifference as they would flies. Bees are susceptible of right and wrong in their transactions with the bee keeper, and appreciate kindness as fully, as some at least, of our own species.

Do not over stock your premises. It is necessary that there should be labor enough for the hands to keep them all busy. In this way they will keep in health, and when a strong vigorous swarm exists, there is but little danger of invasion by enemies.

Cultivate flowers, especially the white clover, a beautiful plant, which is very ornamental to high-ways and pastures. If your bees do not derive sufficient benefit from it to compensate you for your pains, perhaps your cows will. Cat mint is also a favorable plant with them, not for its medical properties, for industry gives them health, but for the honey they extract from it. The currant, gooseberry and raspberry are also valuable for them. So is Mignonne one of the prettiest little flowers of the garden and long in bloom. Set the plants two feet asunder and it will occupy all the ground.

Mount Oscola, 1842.

Naked Barley.--A Substitute for Wheat.

MR. COLMAN--In a late number of your paper I observed a notice of a new kind of barley called "Pearl Barley of the West," which was grown last season in some part of Michigan. The same kind of grain, I presume, has been cultivated for two or three years in this vicinity; and the notice above alluded to reminded me of a beautiful crop of it which I saw growing last summer upon the farm of Mr. Walter Gillespie, a successful and enterprising farmer in this town. Subsequently I made inquiries respecting it, and I subjoin the information gathered from him.

This barley is six rowed, and resembles very much while growing the common six rowed barley; it is a naked barley, the grain threshing out clean from the husk or hull like wheat; the berry is about the colour of the red chaff wheat, but in shape somewhat longer. The quantity of ground sown was about two acres in an orchard; soil a light sandy loam; the previous crop was barley of the common kind, the stubble of which was plowed under, the seed sown upon the furrow and harrowed in. Three bushels of seed were used; the crop was mowed and gathered up in the same way as hay; and when threshed and cleaned it measured a little over fifty bushels, and weighed sixty five pounds to the bushel. Mr. G. has had some of it ground and bolted, the flour was very fine and white, more so than that from our best winter wheat; indeed the miller stated that by these two peculiar properties only, could it be distinguished from superfine wheat flour. The bread made from it was whiter than wheat bread, and would not be suspected as being

any thing else by the taste. I have heard but one objection made to this grain here, and that is the difficulty of threshing it—from its adhering so firmly to the straw. But this objection will not have much weight with a good farmer, for what is not separated adds to the value of the straw by making it more palatable to his stock, by whom it is devoured with great avidity, and thus goes to a good account not only in the improvement of their condition, but also as a substitute, and a cheap one too, for hay. But my object in calling your attention and that of your readers, and more particularly those of New England to this grain, is to suggest to them the cultivation and use of it as a good substitute for wheat, if it should prove, as I think it will, a cere crop on such soils as are not adapted to the latter. And as the seed can now be procured for about the price of common barley, and the expense of cultivation would not be great, I would respectfully recommend to my brother farmers "down east" to make a trial of it, and give the result through the columns of your paper.

Mr. Editor, I am a plain practical farmer,—one of your straight forward, every day sort—having always the scare of that most ancient and honorable occupation upon the palms of my hands. And I would here like to say, not only to you but also to your host of readers, that when you see a communication with my name attached to it, you must not expect to find it written in a smooth, flowing, finished style, with a studied degree of perspicuity and elegance, according to all the rules of silk glove husbandry. But you will rather find it plain, off-hand, farmer-like; using as much as possible the manner and the terms of an every day conversation between farmers. And I cannot but hope that you will grant me your forbearance and forgiveness, if I do occasionally

"Knock pronouns, nouns and verbs about,

Put adverbs in a hurry;

Run interjections out of breath,

Conjunctions bury quick;

To the real death of Dikwot, Dyke, Horne Tooke and Lindley Murray."

J. HORSTFIELD.

Castile, Wyoming Co., N. Y.

[We are always glad to hear from our friend Horstfield. We like his plainness, frankness and spirit. If he does not write good grammar, we have not discovered it. We know what he means; and that is all we want to know.]

The Naked Barley of which he speaks, or as some call it the Wheat Barley, is not unknown at the East. We have seen it repeatedly, and in one instance we knew a trader to take it in for a new species of wheat. But whoever eats wheat bread and barley bread near together, will not be at a loss for the difference. The difficulty of threshing is not of much consideration. The grain deserves cultivation and makes good bread when warm, if the bread-maker does her duty. By Davy's tables, barley meal contains a large proportion of nutritive matter; being 920 parts in 1000, viz.—790 of mucilage or starch, 70 of sugar, and 60 of gluten. It is highly nutritious when mixed for cattle and swine. —Editor.]

Value of Agricultural Knowledge.--Rolling Land.

MR. COLMAN.—Having been a constant reader of the *Genesee Farmer* since its first publication, I have been interested and have found it profitable to practice in accordance with its recommendations.

I have also been much assisted in the arrangement of my farm, in preparing the soil for different crops, and in determining what kinds of grain will follow each other with success, by the experience and experiments of brother farmers, as made known through your valuable paper.

This is an age of experiments, and this accounts

for the valuable improvements in agriculture made at the present day. If I understand the character of your paper, in it there is a door opened through which farmers (though living in different parts of the state or of the United States) may, as it were, meet in one general delegation and confer together, by relating the results of our experience and the improvements we have made in the culture of the soil. By taking advantage of the privilege you set before us, the improvement made by different farmers in agriculture, will not only benefit themselves individually, but the whole mass of farmers who wish to become enlightened and profited by the great improvements of the day.

I am fully sensible, that the influence of the light and truth, now being disseminated throughout our country by the means of agricultural periodicals, is what the farming interest has long needed. Through these means we have the assurance of great and lasting blessings to the farming community; and in the same ratio that they are blessed the whole of mankind is benefited. Your paper, with others of a kindred spirit, is exerting an influence through which the country fellow, as he is sometimes called in derision, is to be elevated to a man among men, to his proper standing and character in the community.

Farming has had my attention and labor from my youth, and as I have endeavored to influence farmers to speak through your paper to other farmers, I would not be behind hand, though I have nothing remarkable to communicate. I would say one word as to the practice of rolling land.

This practice is beneficial in most cases, especially on a loose soil, and especially so when we sowed down land with spring crops. By rolling land after the grass seed is sown, it compacts the earth around the seed without covering it so deeply that it cannot come up; it assists the earth to retain its moisture; the seed sooner sprouts and comes up, and the drought does not so readily destroy it.

I sowed a field of nine acres to clover with oats last spring, rolled it with a heavy roller, and the seed took well and looks finely, whilst most other pieces in this neighborhood were cut off by the drought. It was also beneficial to the oat crop. It was a field upon which I had raised five successive spring crops; five acres of the nine had never been manured, the rest not heavily.

I sowed upon the nine acres 30 bushels of seed; they stood up well when I harvested them. I threshed them the last winter and had 575 bushels, weighing 34 lbs. to the bushel, averaging about 64 bushels per acre.

Land should always, if possible, be dry when it is rolled; then it does not make the earth hard and impenetrable to moisture.

Yours with respect,

JUSTUS TOWNSEND.

Ira, March 26th, 1842.

[The above crops must be deemed large, and Mr. Townsend's experience of the value of a roller on his farm, is fully confirmed by the experience of every other farmer, who has judiciously used one. No farmer should think of being without a roller hardly more than he would think of being without a plough; that is a roller should be considered as absolutely indispensable. —Editor.]

An Apology for not Advocating High Tariff Restrictions.

I was somewhat surprised to learn that my January article on Tariff and Home League, was regarded by a subscriber and his friend as evidence of a want of patriotism in the writer; the more especially as I have ever advocated in the columns of the *Farmer*, the importance of fostering domestic industry, and building up a home trade as a certain market for the farmer, a

hold of hope, ten fold more sure and steadfast, than all the foreign demand of all the world besides. The subject most certainly demands the freest discussion and inquiry, and if I mistake not, the great bulk of the candid and inquisitive rural readers of the *New Genesee Farmer* at least, are not averse to that free discussion on the subject of national economy, which alone can keep us as a people, intelligent and free. I have supposed that every farmer wants to know why the times are so out of joint, and if I give him my simple opinion of the causes as I understand them, or by virtue of my poor experience, I hope he will not arraign my patriotism, for I love my country in these last days of her gambling excesses, as a mother loves her long lost prodigal son.

The theory of a protective tariff and retaliatory duties, recommends itself directly to the feelings of the superficial observer, and he becomes averse to listen to the detail of such facts as may overthrow his long fortified position. The restrictive policy of England is cited by high tariff advocates, at one time as an example for us to follow, and at another time as giving necessary cause on our part for the enactment of counteracting restrictions. But when we reflect that the restrictive policy of England has grown with her growth, until such is the fearful fictitious state of her civilization, that free trade would at this time only compass her utter desolation; ought we not to pause before we follow the example of England in her career of high tariff restrictions; at least to the extent which is proposed by the high tariff advocates of the present day.

A cold damp climate, a contracted territory, and a dense pent up population, present the excuse of stern necessity for Great Britain. But with our extended country, all producing soil and sparse population, we are reduced to no such hard alternative. Counteracting restrictions would only aggravate the ills we suffer. Can it for a moment be supposed that England will ever cease to stimulate her agriculture to its highest point of production, when that agriculture as it is, only can enable her to exist in time of war, to maintain her political integrity, and feed her masses independent of aid from without? Will a nation whose enormous home trade is little less than £400,000,000 sterling consent to prostrate the great supporting interest of that home trade, in order to encourage a trade of a few extra millions with us? I think not.

Why is it that New England, the great workshop of the union has never advocated a high tariff? because her sound laws have kept her currency sound; while Pennsylvania, a state with a population equally frugal and industrious, is crying out in the dark hour of her distress for a tariff, thus vainly hoping to cure the evils of a legalised depreciated currency, by a collateral inflation.

I am in favor of a tariff ample for the purposes of revenue, framed with such discrimination as will favor both revenue and protection to our home industry. Any higher tariff than this cannot fail to be disastrous to the three great interests of the nation, agriculture, commerce, and manufactures.

Waterloo, March, 1842.

S. W.

Envy.—Envy ought, in strict truth, to have no place whatever allowed it in the heart of man,—for the goods of this present world are so vile and low, that they are beneath it; and those of the future world are so vast and exalted, that they are above it. —Lacan.

Workmen should be especially careful to treat each other with urbanity, and politeness. They will always feel better for it and command the respect of others. Politeness is what every man owes to every other man, be he acknowledges worthy of respect. —Elerator.

ROCHESTER, JUNE, 1842.

Acknowledgements to Correspondents.

Cast Iron Sun Dial.—We acknowledge with pleasure an Iron Sun Dial from Sheldon Moore of Kensington, Conn. It is well cast and neatly graduated, and may be confidently recommended to farmers, who now go by a 12 o'clock mark, and some of whose wooden clocks from the land of steady habits are quite sure to be right twice in twenty-four hours, because they politely wait for the hour to come up to them. Heaven sends to man no more beneficent monitors than those which mark the flight of hours. They seem sometimes very unseasonable and often sad, but always useful counsellors.

Subsoil Ploughing.—S. A. inquires what is subsoil ploughing, and if it is any thing more than ploughing a field deeper than it was ever ploughed before? Subsoil ploughing consists first in making a furrow with a common plough, say six or seven inches deep, and then following in the same furrow with a plough constructed for the purpose without a mould board, which shall effectually loose the ground eight or ten inches deeper without bringing it upon the surface. By this process, especially connected with a thorough system of under ground draining, the whole land being loosened to a depth of sixteen or eighteen inches, all superfluous moisture is carried off, air and warmth are admitted into the soil, by which vegetation is greatly advanced, the roots of the plants more easily extend themselves, and portions of the lower soil being gradually brought to the surface, the whole becomes by degrees enriched under the action of the atmosphere, and by cultivation.

Remedy for Heated Cattle.—S. A. recommends when an ox suffers by heat, to throw salt down his throat at the rate of a pint per day, and to do this day after day, until the ox has quit complaining. This would be effectual without doubt; but would it not be quite as well to salt him regularly in the barrel? This giving a sick animal medicine until he has done complaining reminds us of the practice of some physicians, (Quack doctors beyond all doubt and none of the Medical Society,) who succeed in stopping all complaints but those of the heirs of their patients when their bill comes to be presented. It is somewhat akin to De Foe's *Short Method with the Dissenters*, recommended to the dignitaries of the established church, which advised to hang them all.

Social Evils.—The communication of Veritas upon Social Evils is under advisement. Her politeness is respectfully acknowledged. Her views are strong; in the main just; but if she gives us a third specimen of her quality after this fashion, we shall set her down as an arrant scold; the last thing that would ever come into our heads; when we look in her face and hear the natural tones of her gentle and musical voice. She charges us with deficiency of hope and want of trust in Providence. We have trusted in Providence all our lives, but still don't find things come out just as we would like to have them. The reason, we believe, is that our views do not exactly accord with those of Providence. Had we made the world we would have had no storms, no night, no sickness, no sin, no suffering, no death. But Providence permits all these things, which we call evils. Many people often ask us, can't you trust in Providence to put an end to war, and slavery, and drunkenness, and oppression? We could, if Providence would regulate its measures by our con-

coited wisdom; but what folly and presumption and madness to expect this! As these things have been suffered to prevail ever since man was created, experience certainly gives us no reason to suppose that they will not continue as long as man continues to exist. We will contend against existing evils as long as we can and with what little strength we have, and be thankful when the sun breaks through the thick cloud and cheers us with a spot of light, if no bigger than the palm of our hands; but we confess, after the experience of more than half a century, it is almost hope against hope, and is somewhat like a man's venturing into the rapids of Niagara. If by chance he gets back with his life, he is sure to come out dripping and bruised; but he is most likely to be carried down by the torrent, which seems destined to flow on, who can say how long, in all its violence, turmoil and frenzy.

Zelia has fled and is clearly guilty of a breach of promise. If we had her true name we should find a legal remedy. But like a South American belle, she wraps herself in her incognito. With our friend W. B. it is clearly a dead shot. His charmed imagination has invested her with every thing beautiful and celestial. It is cruel thus "to strike and conceal the hand."

To W. C. W.'s inquiries respecting the plan of building described in our April number, we answer,

1st, It would undoubtedly be better to have the lumber well seasoned on account of the plastering. 2d, Boards 1 1/2 inch in thickness would answer as well as inch boards,—the thinner the boards undoubtedly the firmer the work. 3d, We are not prepared to say that it would not be equally well to lay the boards in line mortar as to nail them; but have not seen it done. It strikes us favorably.

Flora in reply to Zelia, J. S. D. on Condition of the Farmers, Turnspiced, Inquiries respecting Wheat, J. R. B. on Silk Culture, S. C. L. on Threshing Machines, J. W. S. second valuable communication, B. M.'s remarks on Condition of English Farmers, inquiry respecting White Daisy, J. Mc. L.'s inquiries respecting Stearine from Lord, J. C. on the same subject, A. G.'s plan of a Cheap House, B. K. D. on Pruning, and various other favors, which we have no room even to particularise, are necessarily excluded by the press of matter previously received. We shall do what we can to clear the docket at the next session of the court, and hope our friends will give us many new cases.

Plagiarism or Poaching; or in the language of the Coves, Lifting.

The Farmer's Gazette in Conn., publishes, without the customary credit a long article, which cost us some pains to prepare, on raising Indian Corn for fodder. This is soon after copied into the American Farmer as from the Connecticut Farmer's Gazette, and now reappears in the Southern Agriculturist under the same head. This is all very gratifying to our self-esteem and our honest desire to be useful. As to its moral bearings, we mean the rules of editorial courtesy and justice, we submit to the honest judgment of those who are taken in the fact.

We have been honored in a similar way recently by our good friends the Family Visitor and the Boston Cultivator, which they will probably set down to the head of fair copying; and, as being all in the family, we will not complain. Even the old honest New England Farmer has got some few spots upon its hands. We say this in the most civil and friendly manner; and so sure as we should unfortunately discover that we have disturbed a single live hornet, we shall beat a retreat; and to those who have taken away our coat we shall surrender our cloak also.

But this is not the whole of it. If we were introduced to the public only under such honorable auspices, we should not be so much disturbed by it; but when the bellwethers jump over the fence, all the rest

of the innumerable heads follow. So our old clothes are at last hung out at every Jew's stall in the country, and represented as bronzed and of the latest fashion, without a word being said of the real suttler, nor even of the goose that precees them. Now all this is very comforting to one's vanity, but it does not butter poor Ship's bread.

Sometimes in such cases we think that our wares, poor as they may be, are like the sheep upon the island of Nantucket, where in shearing and killing time, like gentlemen among the umbrellas and hats at the close of a fashionable party, the pretors get upon the rule of taking the best until all are gone. Gentlemen! in all cases of future appropriation, we beg of you to look at the ear-marks. For ourselves, we belong to the non-resistants, and shall knowingly go upon no mareswing expedition. We shall sail under no pirate's flag, though the agricultural sea is now covered with the noblest barks, spreading their canvases to the breeze and laden with the richest cargoes. We navigate only a humble coasting sloop, with a bit of bunting at the mast head merely for a weathercock. We mean to carry an assorted Connecticut variety cargo of nicknacks, useful in a family way, but no wooden nutmegs or basswood melon seeds; and if any of our good friends desire any of our humble wares for use or disposal, they are welcome to any or all of them, if they will not tear off the shop bill. We hope we shall not offend; but for fear, we can only add, "Ripe mended gratis."

Analysis of Soils.

G. W. of Northbridge, inquires as to the analysis of soils. We are entirely satisfied that no common farmer can undertake successfully this difficult chemical investigation. Davy has given some directions for doing it in his Lectures and Chapul in his valuable treatise on Agricultural Chemistry, but neither of them is deemed satisfactory or accurate by modern Chemists. Dr. C. T. Jackson has treated to the subject in his Geological Survey of Rhode Island. It requires apparatus, preparation, and practical skill quite beyond the reach of persons who have not made chemistry matter of long, careful study and practical application. We want, therefore, a State Chemist, whose business it shall be to examine, chemically, soils which may be sent to him. But in order to understand how much valuable knowledge even the most common farmer can acquire of the nature of different soils, we would refer our correspondent to a treatise on the physical properties of soils in the second number, vol. 1. p. 177, of the Transactions of the British Royal Agricultural Society. This is a paper of very great value, and there are several others relating to the same or kindred topics in the same excellent work, which has now reached to its third volume. The paper to which we refer is practical as well as scientific, and has likewise the great merit of being intelligible. We shall presently give it to our readers.

For various reasons, which we shall some time give more at large, we have not the same confident anticipations of extraordinary benefits to be derived from the chemical analysis of soils, which many persons look for, unless by a process not yet adopted, we first ascertain what the soil contains before the plant is grown in it, and what it contains afterwards, that we may if possible, determine what the plant has taken from it. But the great difficulty is, that in the process of analysing the soil, filtering, drying, burning, and so forth, many subtle matters entirely escape; and such new arrangements and combinations take place, that from the condition to which it is then reduced, it is difficult to determine what it was or how it operated in its original condition. We epitomate most valuable results from the analysis of crops and manures, and much from the analysis of soils, but what has

been accustomed in the way of explanation, to serve little else than to convince us of our ignorance and to show us how profound, to human perception are the subtle mysteries of vegetable and animal life.

Convention of Ploughmakers and Farmers.

A convention of Ploughmakers from all parts of the country and others interested, is appointed to be held in Canandaigua on Monday, the 20th day of June inst. This day precedes the meeting of the Circuit Court, when it is expected the cases of the heirs of Jethro Wood against several ploughmakers for an alleged infringement of his patent right, will be tried.

The ploughmakers in different parts of the country have been threatened and visited with vexatious suits on these grounds; and their confident expectation is by eliciting such facts as may in this way be brought to light, to show that Wood had no just claims to an exclusive right in the case; and that the extension of his patent was surreptitiously and fraudulently obtained; and thus put an end to these prosecutions.

It is a subject which concerns all the manufacturers of cast iron ploughs throughout the country, and the farmers generally, who, so long as this claim remains must be taxed for the patent right of every plough they purchase. As much valuable information connected with ploughs and ploughing may be thus incidentally brought out, it is earnestly hoped that the attendance of farmers and others interested will be general.

Canada Thistles.

A correspondent G. K. inquires if "in respect to that vilest of all weeds, the Canada Thistle, something cannot be done for its extirpation. It is really high time that the farmers look to this; and that immediately. If something is not done soon, the whole country will be nothing but thistles. In vain may the industrious farmer cut and plough and plough and cut, and endeavor to extirpate this vile weed, if his neighbor is allowed to supply him from his land; and it would seem as though the seed thus supplied from a neighbor is better than our own."

We agree to all this; and consider such a neighbor as he describes who willingly, by positive act or by avoidable neglect, inflicts any injury upon his neighbor, is even a viler weed than the Canada Thistle, and deserves to have his nose powerfully rubbed with a good bunch of them three times a day until he reforms. But there is no legal remedy in this case, though we think there should be, since there are few ways in which a man can more injure his neighbor than by filling his field with noxious and untractable weeds.

With respect to the destruction of these weeds, a farmer in Le Roy states that four ploughings in a season will effectually destroy them, and that after this he has taken a fine crop of wheat on the same land, considering the ploughing in of these thistles and their decay as a fine preparation or dressing of the land for the wheat. This in some degree conforms to the experiment of Mr. Kelly in Haverhill, Mass., who ploughed in an abundant crop of charlock or wild mustard three times in a season, and obtained a crop of rye of thirty seven bushels to the acre, where before not more than from eight to thirteen had been the usual product. Of this remarkable and most instructive experiment we shall give a full account hereafter. G. K. promises that we shall have his method of destroying Canada Thistles. Try your note by all means. We understand it as now due.

Wind Mill.

J. Horsefield says in a P. S., "Allow me to say to Mr. O. Woyte, that he will confer a favor on me and probably on others, if he will give in your paper a plan and description of the Wind Mill which he noticed in a late number."

Mr. Woyte, please to comply. We know your kindness in days gone by. There are few men of whom we would soon ask a favor.

Your old friend,

THE EDITOR.

IMPROVED SHORT HORN BULL "ARCHER."

OWNED BY J. M. SHERWOOD, ESQ., ALBURN, N. Y.,

Which obtained the first Premium at the Fair of the New York State Agricultural Society, at Syracuse September 29th, 1841.

"ARCHER" is an cow mostly white, with a roan head and neck—his body has some roan spots—was bred by F. ROTCH, Esq., Butternut, Otsego Co., N. Y. Calved 15th of June, 1837. Sired by ROTLO.

Salt and the Grub Worm.

MR. EDITOR.—Through the columns of your valuable paper, I hope to make the public acquainted with the value of the common black grub, as an agent in the cultivation of corn, when their labors are directed by the genius of man. This, sir, is a new position, a position which has for its foundation, that there has nothing been made in vain, but that all things were made for the benefit and service of man and subject to his direction, and that it is only in the ignorance of man that worms and insects become a scourge upon the face of the earth. The grub has been literally cursed for following the instinct of his nature, which teaches him to eat the corn and reject the grass and sorrel, with which our fields are generally filled. Now, sir, if those who have caused the grub and have advised the agriculturist to follow him with a sharp piece of tin or a knife, with which to decapitate him, or to tie him up in a rag and let him float down stream, had but applied common salt to the hills of corn in the place of gypsum, then, throughout the land, the merits of the grub would have been duly appreciated, then he would have destroyed the grass and sorrel in place of the corn,—thus materially aiding the agriculturist.

In my humble opinion, the introduction of salt as a manure, and to prevent the ravages of the grub, will be of incalculable benefit to the country. Upon our farm we have used salt as a manure and as a protection to the corn from the grub, for a period of seven or eight years. We ought to be capable of judging of the benefits which we have received from using it. During this period we have missed the application but one season—the result was the loss of our crop: from a field of about twenty acres, we harvested but one cart load of corn, where, had not the grub injured it, we should in all probability have harvested fifty bushels to the acre. Last season, 1841, we planted about twenty acres; the grubs were so plenty that we despaired of protecting it from them: indeed, upon an average, I should think there were twenty to every

hill of corn. We applied one bushel of salt to the acre; the protection was ample; scarcely a single blade was touched, but every spear of grass and sorrel was destroyed by them, and in this way they assisted in the cultivation. The application should be made to the corn is just peeping out of the ground. The salt should be put exactly upon the hills, and at the rate of one bushel to the acre—more than one bushel to the acre would do no harm, provided it is put on with common judgment. One bushel is sufficient if properly applied.

If you think this communication will be of any benefit to agriculture, you will please publish it and oblige a constant reader of your valuable paper.

THOMAS N. ALLEN.

Salt Point, Dutchess Co., 1842.

There is some wit in the foregoing, and we believe as much truth as wit. We know a farmer in whose statements we place entire reliance, who has been accustomed for years to put a quantity of salt and mix it well with his manure, which he intended to put in the hill at planting. It has happened repeatedly in these cases that his own corn has been uninjured by the grub, while his neighbor's just over the fence has suffered severely. He is confident of its efficacy. The application of salt to the hill, as described by our correspondent, is a new mode.—Ed.

Agricultural Publications.

Wiley & Putnam, New York, are importing and republishing with great spirit, several English Agricultural Publications of much value. *Libby's Agricultural Chemistry* has gone to a third edition at the Cambridge Press. *Dana's Muck Manual* for farmers, is on its way to a second edition. Little & Brown, Boston, are importing constantly many valuable works on Agriculture and Gardening. We shall get up and keep up with our notices of them presently. A valuable notice from J. E. T., of Johnson's Lecture on Agricultural Chemistry, republished by Wiley & Putnam, is necessarily postponed.

[The following article was written for our May number, but was unavoidably deferred.—*Ed.*]

Many thanks to Zelia for her invitation to the "ladies' saloon." We shall "walk in" and have a chat with her, Capt. Colman's label over the door, "no admission to gentlemen," "to the contrary notwithstanding." And if, or supposing, (as the case may be,) the old gentleman looks a little awry at us, why, we'll make the best we can of it, and if he is really vociferous against us, we'll take passage in another boat next time, and ten to one if we do not take some dozen or so of his passengers along with us. But for Zelia, how shall we approach her pure spirit, with a basket of vegetables or a bouquet of flowers? *She is certainly deserving of her choice, one so eloquent in calling her country women to the path of duty in a time of such calamity as the present. Surely she must be one of a thousand. Yet why do we dwell upon the excellencies of one who fully develops her own merits, and who is emphatically "above all praise."*

Floral Department.—Annals.

It is a very common if not almost universal error in the culture of annual flowers, that they are sown too thick. Of course, the consequence is, that they grow up in a dwarfish and imperfect manner. Their thickness should be in proportion to the size which they will naturally attain. China asters and plants of that size, require to be at least one foot apart, in order to give themselves a full development. Zinnias, immortelles, &c., eighteen inches; gillflowers and balsams are very imperfect, comparatively, unless they have ample space; to Mignonette two feet at least, should be allowed. In preparing the ground for the reception of annals, too much pains cannot be taken for its pulverization, nor can it, in most cases, be made too rich. Let not the farmer deem the manure lost which is put upon the little patch which the females of his household ask for their flowers. Though it may be taken from some other portion of his premises, where its good effects would surely have been visible, it will produce consequences of a most cheering character in its present investment, by encouraging his daughters in pleasant habits of home industry, while those of his neighbors, it may be, for want of this health-promoting, good taste-exciting employment on their own premises, may become wanderers forth among the daughters of the land, to their own injury, and may be, to the annoyance and injury of those who ought not to be contaminated by their influence. But if economy, which surely ought to be a universal watchword, should too hard at the idea of a little compost for the parterre, by putting on her spade and pushing her investigation of domestic concerns a little further, after the demands of the farm and the vegetable garden have been supplied, or "every thing has been raked and serped" to satisfy their demands, and they, like the sorrowing creditor, who trusted too far, when the arrogant debtor comes to require an acceptance of a dividend or nothing, have yielded to the necessity of the case, will find in certain by-ways and about hedges enough to satisfy the demands of Flora, which, unless it were gathered up and offered at her shrine, would have been lost, or worse, would have tended to promote luxuriant growths of weeds, the vile pests of the farmer's interests, and foul spots on the beautiful surface of his cultivated territories. If this plan is thought foolish or wasteful or out of place, we have another remedy to apply, by which these objectors may pursue the even tenor of their way, and yet flowers be made to spring up and bloom in loveliness and beauty and perfume the air with healthful fragrance. This is to throw the haulm of the flowers into the farm yard when the season of flowering is past, instead of allowing them to remain upon the ground over winter, to be burnt in the spring.

In this way, flowers will work their own passage and pay toll. The form of flower gardens, is lost when left to the taste of the occupant. Thus a great variety of flowers, in passing through a country will present themselves, to invite the attention and excite the admiration of the beholder.

The Strawberry.

If any thing can be more disagreeable to the mind (i.e. as regards man's local habitation) than a large and elegant dwelling, freshly painted and adorned with its bright green shutters, with yards around it filled with dock, thistles, or any of the &c. family, with here and there a slough, broken cart, or brass heap, all which go to make up a variety; with the hot sun scalding with his piercing rays the newly varnished castle, or the relentless storms bringing out their fury in mockery of the improvements which enterprise has begun on the premises, without a single shade to give freshness to the scenery, or a single cluster of shrubbery to impart loveliness to the spot, it must be the idea of the deluded spirit of a man who conceives the objects of taste all gratified, and matters of utility all arranged, and motives of interest all fulfilled, when he brings his improvements to the state of things which we have described. Think of it Zelia, there is something wrong, morally and physically wrong, where such a state of premises is found as we have described, and were we a lady, we should reverse the saying of Solomon and conclude that we should live—any where else, "than in a wide house" with such a being as we should naturally conclude occupied the one above noted. Yet we would not influence nor hinder anyone from forming a laqus which should give them internal possession of such premises, but on the contrary encourage it, on a principle of general benevolence, for they might do much good by such a sacrifice.

The front yard (and as much more as they wish) should always be placed at the disposal of the females of the household for flowers and flowering shrubs. In the culture of these, grass and weeds should be as thoroughly extirpated as for a crop of corn. Then they will grow luxuriantly with little care beyond that of pruning, which every one will attend to in order to bring them into the beautiful shape which their fancy may direct. Shrubs, to succeed well, should be removed with care, and may be done either in fall or spring. Trees should be placed on the outer margin of shrubberies for their beauty and protection.

W. B.

Native Shrubs and Plants.

It brings no very cheering reflection upon the taste of the American people, that every thing must be transatlantic in its origin, in order to secure their attachment. But it is too true with regard to many things. Our hats must be of the latest London or Paris fashion. Our boots must not only, in too many instances be of European fabric, but must be of Messrs. Jacques & Co's. last style. Our boots—shoes at least, must be Victoria; and even our American plants, like the aborigines of the country—like the republican simplicity of our forefathers, must be crowded out of the way to make room for those of foreign origin. And this is directly in the face of the wisdom and good taste of our eastern brethren. In all Europe, travellers proclaim the beauty of American forests. Their naturalists have traversed them in their length and breadth; and have carried home at great expense, their rich and varied productions. The Garden of Plants, one of the richest collections in the world, obtained some of its most valued specimens from our wilds, and the parks of the lords of ancient Britain are decorated with trees and shrubs of our republican origin. Though the forests of our country contain far greater varieties than can be found in theirs, they

do not trace to this the cause of their attachment to our plants, some of which bear the names of their most distinguished men. But it is their peculiar and unrivalled beauty which attracts their notice and secures to them a right of soil in the domains of kings and emperors. And it argues well for the veterans of taste and science in those countries that it is so, for there is certainly no portion of the earth that can exhibit a greater variety or more beautiful vegetable productions than ours. What is a fitter emblem of meekness and simplicity than our Arbutus, trailing a humble quietude on the ground, and opening its choicest petals while yet the earth is held in the durance of frosts, and the snows are still unpassed? What fitter emblem of purity than is to be found in the short lived Sanguinaria Canadensis, which comes and goes while yet the frogs are piping the early notes of nature liberated from the bondage of winter? Go into the woods and along the glens at any time while the early season is yet fresh in youth, and what more picturesque beauties can present themselves than those there exhibited? Take summer, the noon of the seasons, and look at the Azaleas, the Kalmias, the Rhododendrons and a thousand other families, which though not of royal blood, have been introduced to royal favor, and where can nature's storehouse furnish objects to charm the eye superior to these? Yet we pass them almost unheeded, or perhaps what is worse we mutilate them in this season of their beauty on glory, to furnish fading memorials of their loveliness for a brief day for our parlors, while the weeping ster from which we robbed our trophies, must in solitude sustain its fair remaining blossoms.

To bluish unseen.

And waste their sweetness on the desert air."

When if the root and branch were removed to our dwellings and given a kind location there, they would charm in some varied form at all seasons, and in the bright time of flowers, regale our eyes and perfume the atmosphere through the period of their floral existence, without the necessity of a daily renewal as the vase or recourse to artificial means. Let it be inferred that we would exclude foreign plants from our grounds, far from it. We admire and would cultivate them by all means, but let us not stumble over those all around us, to catch greedily at the "feet and dead bought." But we must leave the Saloon, Zelia, and go on deck and try to make acquaintance with Capt. C.

W. B.

NOTICES.

Address before the New York State Agricultural Society in Albany, 19th Jan., 1842. By J. B. Not

Esq., President of the Society. This sensible address has at last made its appearance. Immediately on its delivery we gave from our notes a sketch of it. In comparing our sketch with the address, we are happy in finding that we had given in the main a just account of its views and sentiments, and in but one instance, and that of trifling moment, had we misrepresented it. The manuscript was of course far inferior to that flowing and classic style in which the author presents himself. We should have been happy to republish the whole address, but as it will be circulated throughout the state, as we have given an extended sketch of it, as our columns are crowded we must forego any other pleasure than that of presenting the subjoined extracts.

"Young men, after having finished their academic course, are embarrassed in the choice of their future professions, for they find the professions crowded to excess; so crowded that men of fair talents and respectable industry are rewarded only by a mediocre success. Hence it is that we unfortunately find many too many otherwise respectable men of all political creeds, who are ready at any fortunate crisis to abandon their professions and seek instead, the rewards of office. I do not speak of those whose ambition prompts them, regardless of the cost, to climb the

dd eminence which has always been found, it is said, "narrow for friendship, and too slippery for safety" for this is a legitimate, though alas, a dazzling object of pursuit. But I speak of those who make political pursuit a mere question of profit and loss, so such men we can point out a field of exertion, here at least "for a portion of their life, their power would be employed in a manner less revolting to conscience; and with results quite as useful to their country and to the world."

It is important therefore to do away the erroneous impression that there is no other pursuit worthy the attention of an educated man, than the so called liberal professions, and that a liberal education is thrown away if bestowed upon a farmer. If the farmer must by necessity be a mere rustic, and any one who engages in the pursuit, will allow himself to sink to this ignominious level, then will a very humble education fit him for his untoward destiny. But if a farmer is desirous of taking rank with the Gaylords and the Phineys, of our land, and with men of kindred spirit in their lands, then will his calling give abundant occasion to his talents, however guided, and his attainments, however profound. This is not all; a farmer may be even a man of refined taste and exquisite genius. A good farm should not be characterized alone by its trim fence and its straight furrows, but it should also be an object of beauty. "Man made the town, God made the farm;" and it ought to bear the impress of his beautiful workmanship. There are farms too, where, by the skillful disposition of wood and of shrubbery, there is, as it were, grouped into a scene of surpassing loveliness, the beeding cliff, the smiling meadow, and the meandering river. And still the claims to taste and genius be denied to a farmer, because it is such a secular and lowly avocation, worthy to him who can transfer it to the living canvas? It may be said that these higher accomplishments, constitute no part of practical farming, because it contributes nothing directly to a farmer's prosperity. "To such men," as Cbeever says, "God himself, as the creator of the universe, cannot appear as an architect of practical wisdom, for he has covered the earth with objects, the sky and the clouds with tints, whose surpassing beauty is their only utility. This beauty is eminently useful, because man who beholds it is a moral," as well as a thrifty being—"because it awakens the soul to moral contemplations, excites the imagination, softens the sensibilities of the heart, because it tells him of his mortality and his immortality, giving him symbols of both, and holding with him a perpetual conversation of the glory and wisdom and goodness of God."

"To some, the meanest flower that blows can give Thoughts that do often lie too deep for tears."

If I am asked whether the pursuits of literature are incompatible with the practice of husbandry, I answer that they are at all events incompatible with the practice of a profession. Whoever would woo the muses must bid farewell to professional eminence. But there are farmers, thrifty laborious farmers, men exposed to the summer's heat and the winter's cold, who are well known in the walks of literature. Why should it be otherwise? There is not an operation of practical husbandry, however humble, that is not immortalized in Thomson's, or Gray's, or Cowper's song. To such men, how melodious was the reaper's song, how graceful the mower's movements, how picturesque the loaded train, groning beneath the burden of the gathered harvests? Much more then should rural pursuits awaken the high souled eloquence of those who are habitually engaged in them. There was a time, it was olden time "dear, but there was a time when pastoral life was deemed especially favorable to sublime conceptions; and one shepherd at any rate has raised through many an age the loftiest emotions, who exclaimed as he stood and his flocks raised his contemplative eye to yonder firmament.

"When I consider thy heavens, the work of thy fingers, the moon and the stars which thou has ordained, what is man that thou art mindful of him, and the son of man that thou visitest him?" Agriculture then, is not inimical to the pursuits of science and literature; but still it is too often deemed a degrading employment. He talks of bees, said Dr. Johnson sneeringly, of one of his most intimate friends, and yet the ill tempered and ungenerous satire is utterly at variance with even his utilitarian notions. In settling the relative ranks of the various callings of life, it should be remembered that we are governed in our views by old and intricate prejudices. The noble by which they are graduated, was formed in the ages of ignorance, when men of the learned professions were monks; men of ambition, soldiers; and husbandmen, serfs. But the times are altered; and the pathway to fame no longer leads exclusively to fields

covered with courage and slaughter, and may yet lead to fields smiling with the gifts of Ceres and Pomona.

We, therefore, who are ardently attached to our favorite pursuit, who are aware of its privileges and acquainted with its delights, should do all in our power to disabuse the public mind of its mistaken prejudices, and to raise it in the public estimation to the level of the liberal professions, so that he may have no fear of losing caste, who exchanges the merchant's counting-room and lawyer's desk, for the pursuits of agriculture.

"Nor ye who live
Think these last things unworthy of your ears.
Such scenes as these the rural Harp sung
To wide imperial Rome, in the old height
Of eloquence and taste, by Greece refined.
In ancient times the sacred plow employed
The kings and awful fates of mankind;
And some, with whom compared your insect tribes
Are but the beings of a summer's day,
Have held the scale of empire, ruled the storm
Of mighty wars, and with unwaried hand
Disdaining little delicacies, reared
The plow and greatly independent lived."

"Generate the plow,
And o'er your hills and long withdrawing veils
Let Autumn spread his treasures to the sun,
Luxuriant and unbounded. As the sea
Far through his azure turbulent domain,
Yet deeper ocean, and from a thousand shores
Waits all the prod of life into your ports;
So with superior boon may your rich soil
Exultant Nature's better blessings pour
Over every hand, the golden autumnal clothe,
And be the exhaustless granary of a world."

Address delivered before the Essex Agricultural Society in Massachusetts, Sept. 30th, 1811. By Alonzo Gray.

This address is very creditable to the author. Its main object is to show the advantages and importance of science to agriculture; its connection with the improvement of the art, with its productiveness and with the dignity and respectability of the agricultural profession. In the main we agree in all the sentiments expressed. If the farmers would elevate their art, they must elevate themselves.

Mr. Gray speaks of an establishment in connexion with the theological and literary institutions at Andover, designed to furnish instruction in gardening and agriculture. These institutions have been endowed with a most extraordinary liberality for the specific purposes of their establishment, and such an addition to their other means of improvement will doubtless prove of eminent utility.

There are particular branches of study directly concerned in agricultural improvement. These should of course be objects of pursuit; and to practise farming with success, a man should become familiar with all its operations; and if not himself capable of performing them, yet capable of determining when they are done and exactly how they should be done. But very much more than this is desirable. The most humane and liberal education will not be lost upon a farmer, unless it should, as it is alas! too often its effect, inflame his mind with foolish pride and self-conceit, and lead him to disdain labor and its humble accompaniments. In all great improvements in any thing connected with human life, society, or the arts, mind is the propelling power. The cultivation and strengthening of the mind, the creating within it a thirst for universal knowledge and continually stimulating this appetite, is the great instrument of success in any and every valuable art or profession. Education for the farmers, as for every other class in the community, should be regarded in its most comprehensive sense, not so much as the imparting of knowledge, this is but a small part of education, but as teaching man the proper use and application of all his intellectual powers, and exciting him to their constant and highest exertions. While, therefore, we rejoice in the establishment of schools designed to teach the practical operations of husbandry, and all the arts and sciences more directly and specifically connected with it, we should insist, wherever we had the power, as

is suggested in Mr. Gray's Address, that there should be associated with such institutions the fullest course of instruction in all liberal arts and in general knowledge.

We should be glad to quote liberally from this address, but at the present we must restrict ourselves to a small portion.

"It is one of the most glaring defects in our system of popular instruction, that no provision is made for the study of those liberal sciences which are intimately connected with agriculture, and a knowledge of which is necessary in order that the science itself may be understood; we are therefore met with an obstacle which it is not easy to surmount, whenever we attempt to instruct the community into the principles of the art. There is wanting not light on agriculture, but a recipient power in the general mind to collect the light which actually exists. There is knowledge enough in the world to save it, if it could be brought to bear upon the popular mind; hence what we need is such an elementary knowledge of mineralogy, botany, chemistry and natural philosophy, with their application to the arts, that the science of agriculture may be understood, and such a discipline of the popular intellect that this knowledge may be practically applied.

For want of this recipient power, the press, that great engine of popular instruction, is deprived of the greater part of its efficiency. Popular lectures, the efforts, the discoveries of scientific men exert but a feeble influence. The fostering care of the Legislature, and the indefatigable labors of agricultural societies scarcely reach the general masses of farmers. The consequence is that no preparation is considered desirable to become a farmer, as if men were endowed for this employment with an instinct like the bee or beaver, which is perfect in itself and could not be improved by education.

While some degree of preparation is deemed necessary to practice the *rudist trade*, that of a *collier* or *common pedlar*, the most difficult and important of all trades may be carried on, it is supposed, without any preparatory or professional knowledge. What should we think of the wisdom or sense of that community which should encourage all its physicians, lawyers, ministers, merchants and politicians to engage in their respective professions without any professional knowledge whatever? And yet there is as much propriety for a young man to engage in the profession of law, medicine, or theology, without professional knowledge, as in that of farming without a knowledge of its fundamental principles. True, he might do more injury to society in the former case, but he would have an equal title to the character of a quack in both; and quackery in farming has many striking analogies to quackery in medicine, and were it not so common, would meet with similar ridicule and rebuke by all intelligent men.

But how can this recipient power be supplied, and how can this professional knowledge be acquired, unless agriculture be made a subject of study? As our common school system excludes those kindred branches of natural science which are necessary to a professional knowledge of agriculture, the commencement of improvement must be made in our academies; and higher seminaries. Our colleges have a different object, their course of study has become too rigidly fixed to be altered, and it is doubtful whether any success could crown the effort if tried. But this is not the case with our academies, and scientific agriculture may be introduced into some of them and taught successfully to those who are to be the future cultivators of the soil. With an institution liberally endowed, with proper able, text books, lectures, apparatus, and experiments conducted in the field, the young farmer, after having received a thorough discipline in a preparatory course, may obtain his education by obtaining a scientific knowledge of agriculture previous to entering upon the great business of life.

We would not establish institutions for the mere study of agriculture, but would connect it with an extended course of English education. We are no advocates of a superficial course of training. We would

* After the subject has been introduced into a few of our higher seminaries, for the purpose of preparing the teachers of our common schools to instruct in the various departments of Natural History, the subject may then be introduced into common schools, and until we have teachers qualified for such instructions, we must confine our efforts to higher seminaries, where those facilities may be furnished which are required for teaching the first principles of chemistry and Natural History. The great difficulty now is that we have neither qualified teachers, nor books, nor cabinets, nor apparatus, which are requisite to prepare men in our common schools for the theoretical and practical parts of agriculture and the various other arts and trades.

new inventions which are continually being made for us. We can by means of our *Fans* see each other, and seeing, he enabled to judge of the effect of what may be offered.

Statistics of Cuyahoga County.—And if the freemen say do not march in the van of the agriculturists, the facts must be theirs. Nature has been no kinder to them; with a soil of great fertility, well adapted to the production of all the principal natural products of this latitude, we have in addition inexhaustible beds of gypsum, quarries of lime, and swamps of marl, with also a fair promise of abundance of soil—all that then is required, is the to do, the energy to perform.

As appears from the census taken in 1810, there are about eleven thousand men in this county engaged in agriculture, while the whole number engaged in all other business was only about four thousand. The greater portion of this eleven thousand men who own the land they occupy, the bone and marrow of the County, the men who pay our taxes; port our schools, who if need be, will fight our battles, have a home and a hearth stone to produce and defend, are a class the most honest, the most moral, the most industrious, the most independent and most virtuous, and certainly such men need only be convinced that their best interests may and will be promoted by this Society, to render them at once willing and anxious to join our ranks. Look for a moment upon the products of this County for the year 1810. As appears from the census of that year, were raised in this county that year more than six hundred thousand bushels of wheat, more than eighty thousand bushels of barley, more than four hundred thousand bushels of oats, more than forty thousand bushels of buckwheat, near six hundred thousand sheaves of corn, near seven hundred thousand bushels of potatoes, more than three hundred thousand pounds of wool, more than seventy thousand tons of hay, more than two hundred thousand pounds of maple sugar were made the same year, and the products of a dairy amounted to near one hundred and ninety thousand dollars. The aggregate value of all the above, the produce of a single year, at present prices, could exceed two millions of dollars, the agricultural products of about eleven thousand men, many of whom doubtless were men who were older upon the soil. Again, as appears from the same Census, there were owned by citizens of the County, on the first day of January of that year, more than thirteen thousand acres, near fifty thousand neat cattle, near two hundred thousand sheep, and more than sixty thousand pigs.

Address delivered before the Medina County (Ohio) Agricultural Society, October 7th, 1841. By Col. Abraham Norton.

This is a glowing and impassioned address in favor of agriculture; inculcating the value and dignity of labor, and urging with great earnestness the cause of agricultural improvement. We give the title as it appears, and though it is not exactly turning a spear into a pruning hook, it exhibits a transformation not very unlike, in changing a military officer into a good farmer.

With all the gallantry of a military man, he speaks thus of the influence of woman in every good cause.

"While the unlettered natives of the earth have either deified woman as a goddess or debased her as a slave, we are delighted to accept her as the equal and honored companion of our homes, and the pride and ornament of our assemblies. At her feet do we learn lessons of mental refinement and moral sensibility. This is no ideal compliment of mine, or vain picture drawn to foster her pride and feed her vanity, but the sincere conviction of every mind susceptible of truth. When the tide of woman's influence is turned to upbuilding of our societies, of whatever name, we ask no surer token of success. With it our highest anticipations are realized; without it our stoutest efforts are paralyzed. Whatever be her enterprise, if successful she is not so elated as to miss her object; if disappointed, she does not give up the pursuit; and if the last prospect of success vanish away, she will not despair, but sit 'smiling at grief.' I care not how great, how difficult and discouraging the enterprise, she has courage and perseverance adequate to its accomplishment."

This is not mere rhetoric, but sober truth; and no one can possibly suppose after this that the Colonel can be a bachelor.

Address delivered before the Agricultural Society of Orange County, November 17th, 1841. By John Caldwell, Esq., President.

This is a valuable address; and we are glad that the farmers of Orange county have among them so enlightened and zealous a friend of the good cause of Agricultural Improvement. We shall give two extracts from the address.

The value of an industrious profession.—Agricultural pursuits are peculiarly congenial to the people of this country, and to our republican institutions, they are the foundation of our prosperity and the main link in that chain of connection which binds us together as a nation, and contributes to our wealth, our strength, and our independence. It is, therefore, gratifying to observe the lively interest every where taking in the cultivation of the earth. It was grossly neglected in the former ages, when speculation in building lots on the mountain tops, or even in the moon, seemed to overturn the world with madness; the dire results of such infatuation have cured the error, and rationality is again restored, though at heavy sacrifices to the bewildered victim of cupidity. Manufacturers, Commerce, and the mechanic arts, owe, as to an indulgent, fostering mother, their protection in infancy, and their success in the after days of their progress, to the never failing aid of successful agriculture. Is it not, therefore lamentable to see so many of our vigorous youth, to withdraw themselves from its ennobling pursuits, to desert their sweetens, not as the Poet says—"to the waste air," but behind the counters of petty and inefficient traffic? Thus, too, by filling saloons peculiarly suited to the softer sex, depriving thousands of unprotected females of appropriate employment, and compelling them to earn a scanty subsistence in such other ways as remain open to them, by incessant, but ill-regulated labor; often at the expense of health and constitution, worn down spirits and broken hearts. This is no exaggerated representation; let any of you visit the modes of honest poverty in our cities, and you will find it more than realized. One of the ablest periodical writers of Great Britain, speaking of the ambition in that country for professional life, the rush into what are called the learned professions of law, physic, and divinity, points to some of the consequences in language which is no less applicable here.

"But thousands," says he, "have died of broken hearts in these pursuits,—thousands who would have been happy behind the plough, or prosperous in manufacturing or mechanical pursuits;—thousands in the desperate struggle of the thankless professions, look upon the simplicity of a life of manual labor with perpetual envy, and thousands, by a worse fate still, are driven to necessities which degrade the principles of honor within them, accustom them to humiliating modes of obtaining subsistence, and make out by administering to the vices of others, the livelihood which is refused to their legitimate exertions." There is, however, in this our beloved country, a general feeling, which pervades the entire mass. An idle man, however wealthy, is looked on with contempt, and can never enjoy the confidence or respect of his fellow-citizens.

Habits of exact observation encouraged.—While I congratulate you on the vast amount of useful matter scattered over the land in these periodicals, I object to the unnecessary parade of scientific terms, frequently unintelligible to plain men like myself, which there is reason to fear deters many from looking at them at all. A woman may bake a good batch of bread in total ignorance of the theory of fermentation, and a farmer may raise a good crop, and know little of the alluvial fertilities of soil and manures. It is well—it is praiseworthy for those who have leisure, talent and inclination, to pursue such investigations, whilst the practical man applies them to his every day pursuits. Indeed, the whole process of cultivation may be considered as a well arranged series of experiments, and every intelligent farmer an experimental philosopher, the soil his subject matter, the elements his agent, and his laboratory bounded only by the wide canopy of heaven—there he follows up causes to their effects; there he traces back effects to their causes, and there too, in the midst of his labors; he looks from nature up to nature's God. But allow me, gentlemen to suggest that, as in all other arts and sciences, so also in agriculture, the various operations as they occur in the successive stages of the process, ought to be carefully and minutely noted, and for this purpose; it is the

practice of some intelligent farmers, to keep a farm book, in which every lot is designated by number, or otherwise, and the treatment to which each is subjected in each year regularly recorded, thereby laying the basis for just conclusions, from well established premises.

Leaves for Manure.

An enquiry comes up in the second number of the current volume of the Farmer concerning the leaves in "hard wood land" being used as a manure, and the success attending. In answer to which we say, that if the land produces only hardwood, they furnish the principal manure for the timber when growing, and for other purposes when the wood is taken off. The growth of such timber is usually of a profitable and sometimes of a rapid character. The land where such timber is found, is of various but generally productive character, and retains its fertility well.

Taken from the forest and placed in the sty or barn-yard, where they can be subject to the operations of swine and other stock, and it forms one of the most valuable manures, both for present use and future durability, that can be employed. It answers well for all kinds of crops. In the crude or unmanufactured state, in which it is taken from the woods, the manure is perhaps as good as any for potatoes in the hill, for fruit and forest trees, currant bushes, &c.

For the New England Farmer.

Harrowing Potatoes.

FRIEND COLMAN.—It is not my object to argue the profitability of a crop of potatoes, or how the greatest quantity can be raised from an acre, but to suggest an improvement in the cultivation of them. My practice has been, for two or three years, with a light drag to drag them over thoroughly, just before they come up. My objects in this are to pulverise the ground well, which it will do without injuring the potatoes, if they are planted at a proper depth, and destroy the weeds that get up generally very much before hoeing time. By these means the crop is kept much cleaner with less work than any other way that I am aware of.

ESEK WILBUR.

Maclean, 4th mo. 23d, 1842.

We have seen this method practised with much advantage, and know that it greatly facilitates the cultivation of the crop.—Ed.

TO THE POINT.—When the Mayor and Common Council of Albany, at the opening of the Western Rail Road, visited Boston and were received by the municipal authorities in due form, the Mayor said for himself and associates that they would be glad to see the city; he was a business man, and not used to making speeches.

A captain of a merchantman whose cargo was consigned to Sam'l Williams, the eminent American merchant in London, not finding such a market as he desired wrote a letter of three quarto pages for advice as to what he should do, proposing this and proposing that course. Mr. Williams' reply, very much to the chagrin of this long winded gentleman, was, "Sir, take salt and go home."

Farmers! no long talks in the morning. "Take time by the forelock."

Cure for Wounds, Galls, and Bruises.

Take one quarter pound of Saltpetre, half a pint of Vinegar, half a pint of Spirits Turpentine; put them together into a bottle, and shake up before using. Apply it to the wound with a feather, three times a day.

The above was handed us by a highly intelligent friend, who assures us that it will be found a most efficient cure for sores on horses.

The Season now, 30th May, has seldom promised better. The wheat looks finely, and grass abundant. The prices of produce are such as to satisfy reasonable men; wheat in Rochester, \$1.25 per bushel, and hay 10 to 12 dollars per ton.

For the New Genesee Farmer.

Sowing Corn for Fodder.

MR. COLMAN—In the Farmer for March, your correspondent Ledyard asks information on the subject of sowing corn, bread east, for winter fodder. I was, at first, surprised at the enquiry, but on reflection, concluded he must have been a stranger to your paper, probably just then commencing an acquaintance with it. I ask leave, therefore, to refer him to your number for July, 1841, page 109. He will there find an article on the subject, that will, I think, in a measure satisfy his enquiries. I have been for twenty years accustomed to this culture, and have there given the result of my experience. I do not feel as if I could say too much in its favor. The product per acre, on a rich soil, and in a favorable season, will be very great. I have never had occasion to ascertain with accuracy the amount. But have considered, or estimated the amount on different fields and in different seasons, to vary from five to seven tons, or more per acre. I have carried well a very large stock, rising 1000 sheep, and many cattle, far into January, with very little hay.

I would by no means suffer the corn to stand to let the ears ripen before harvesting. It should be cut when most juicy, when the juice is richest and sweetest. This will be, I suppose, at the time when the kernel has become nearly or quite full of milk. When sown 2 1/2 bushels of seed per acre, the quantity which I recommend, and from which I would not vary, it will stand so thick and the stalks be so slender, that but few ears will set. Cut up at the time I propose, it will be so extremely succulent, that it will need to stand in small stooks to cure, during the dry and hot weather; and should be put into stacks, as recommended in the article referred to above, just before the fall rains commence.

The idea suggested in the Farmer for March, page 21, "that weeds will check its growth, if the land is rich, and fill the ground with seeds," I cannot think correct. It is entirely at variance with my experience. The ground is so deeply and perfectly shaded, that I have found nothing could live or grow among it, save the Canada thistle; and this would shoot up a slender, pale, weak, and sickly stalk, unable to produce or sustain a blossom.

I have been pleased, after taking off the corn, with the condition of the ground for cross-ploughing and sowing with wheat. I recommend to sow corn early, that it may be harvested early, and thus have the full benefit of the dry and hot weather, for the process of curing the stalk. If cut late, it will be more difficult so to cure it as to secure its safety. I once lost a large quantity, supposed well cured, by stowing it away in a large and solid mow. Of course, I prefer staking it, as recommended in the article referred to above, around a pole, the length of a sheaf only from the pole, so that the butts shall all be exposed to the air.

April, 1842.

A FARMER.

Mildew on Gooseberries.

For the New Genesee Farmer.

MR. COLMAN—One of your subscribers inquires how he shall prevent gooseberries from moulding. Some few years since, while passing through the Shaker settlement in Hancock, Mass., we stopped (its a gift of ours) to chat awhile with one of the brethren. Among other topics our conversation fell upon gooseberries. He said they had a very fine variety, but in consequence of their mildewing, he was going to pull them up and throw them into the street; they were useless to them. We made a truce with him for the said rejected bushes, brought them home, and put them out as we had been wroth to put out gooseberry bushes in former time. It was too late in the season to expect any good from them that year, for their blighted fruit had just fallen prematurely to the earth. The next season, however, brought

us a harvest of fruit as large and larger than robin's eggs, as clear as a quill, and as delicious as a plum or peach if you please. And the said bushes continue in good bearing ever since without any change of local habitation or name. My management with them has been to keep the earth light and rich around the roots. If moss collected on the stalk scrape it off, and cut the old stalk down once in about three years. The bushes must be kept well pruned, which is not very difficult, if you have a choice fruit, and set them where the air will circulate freely. A cold exposure is injurious to their tastes, habits and constitution.

A very dry and wet taste unfavorable to their growth, as we have, in several instances, known of their being attacked by mildew in sandy soils, also in those where rocks lay but little distance from the surface. The best we ever saw, grow in a moist loam, which was kept enriched by decayed chips.

W. B.

Mount Osceola, 1842.

For the New Genesee Farmer.
Summer Cooking Apparatus.

I furnish a description of such an apparatus; which I have found cheap in construction, saving of fuel, and very comfortable indeed for the woman who used it. Though perhaps not adapted, in utmost strictness, to an agricultural journal, cobblers and carpenters being sometimes compelled to do their own cooking, still I flatter myself it will not be excluded, while the columns of the Farmer are open to long *funnyisms* about Connecticut River letters, old bachelors' griefs, and young ladies names.

The apparatus in question, consists of an iron vessel A (represented in section,) having a large hole at the bottom covered with a grate B, firmly set in solid brick-work. This is for containing the fire. Directly beneath it is the hearth C, enclosed on all sides, except a small hole in front, 2 or 4 inches, for extracting the ashes, and for the admission of air to the fire above. To this hole is accurately fitted by grinding a piece of brick, so that the draught may be entirely cut off, when the fire is not to burn rapidly. D is the boiler, made, as is perceived, in the shape of a frustum of a cone inverted; and when set in, leaves an average space of one or two inches for the upward passage of the smoke. On opposite sides of the iron vessel A containing the fire, and the thickness of one brick from the top, are two square holes for the horizontal passage of the smoke to the chimney. The position of one of these holes, is represented by the square dotted figure. A chimney about 5 inches square and four feet high, will afford draught enough, and may then pass into a common brick chimney; or a feet of stove pipe will answer the same end. Several boilers of this kind may be connected in one mass of brick work, and then form what are termed in some of our cities *kitchen ranges*, where they are not very uncommon.

The fuel used may be small blocks of wood, chips, or charcoal. If charcoal is used, less space should be allowed between the grate and the boiler, than when chips are burned. From three to six inches is sufficient. The quantity consumed is exceedingly small. The stratum of hot air round the bottom and sides of the boiler, is so thin, that little heat comparatively escapes, acting, as it does, on a principle similar to that of Mott's Agricultural Furnace. A bushel and-half basket, filled with blocks of wood, were enough to

cook all the food of a family of four adult persons for two days. By shutting the draught, combustion continues for a long time. Three blocks of wood, of size of common half bricks boiled the dinner pot with 7 quarts of water, at 11 o'clock, after which the draught was closed, and they continued to burn, keeping the water at boiling heat until 5 o'clock for boiling. A pint of charcoal was sufficient to boil 1 quart of cold water.

The fire communicates scarcely any perceptible heat to the room, hence it is particularly adapted for summer use. Every woman (I don't mean ever lady, whose fingers never bent for household duties, every woman knows that ironing clothes, and baking griddle-cakes, is desperately hot work in summer but not so with this apparatus. With it, she may iron as comfortably as she takes her flower bed; and bake cakes, sitting in her easy chair, as easily and coolly as she writes a letter. I have seen it done.

The vessel A would be best if made of cast-iron. Mine was made of thick sheet-iron, and though the lower part burned through in a few months, yet the bricks, having been made to fit its outside, still kept the proper shape. The upper rim of this vessel, on the shoulder of the boiler, should fit accurately. Cooking-stove boilers may be used, but being shallow below the shoulder, are not so economical of fuel.

The cost of a single boiler apparatus was as follows:—

Sheet iron vessel A A.....	\$0,83
Tin boiler D.....	1,09
Grate.....	25
Brick and mortar.....	1,75
Mason work.....	87
Iron strap round the top layer of brick to keep them firmly together.....	25
	\$5,00

When the boiler is of moderate size, fuel is put in at the top, by removing it; but when very large, small door is fitted in front to shut very closely. A valve shutting the flue above the fire would be a very good thing; and the air passing thus excluded from above as well as from below the fire would keep as well as when covered with ashes.

Western New York, 1-42.

Value of an Agricultural Paper.

Extract from a private letter from one, whose intelligence and experience gives him a right to speak with authority, in Ontario county, and dated 4th March, 1842.

"I want the farmers to cast away their prejudice against reading an agricultural paper. I think they are afraid of being caught in reading something, which perchance may have been written by some one, who does not belong to their calling, in whose views the night coincide. They are not compelled to practice any information communicated, which does not commend itself to their common sense and judgment.

cannot be that the charge of fifty cents prevents the taking an agricultural paper which usually contains a single number information respecting some subject worth more than the entire cost of the paper for whole year's publication. But light is gleaming through the mist of ignorance and prejudice. The farmers are waking up, and that over-weening confidence in one own experience, possessed by many, is giving way. Many are willing to read an agricultural paper, are not ashamed to confess that they find it useful and instructive to them."

We cannot help considering this advice as sensible and sound; and therefore we recommend to those who need it, to take it. As Quakers often say of the medicine, "it won't hurt you if it does you no good. Ignorance and prejudice are extremely intractable diseases to contend with. Advancing education and the

gradual spread of knowledge, will, by slow and imperceptible degrees accomplish that which cannot be achieved by any sudden movement. That which is gained by the gradual diffusion of light and knowledge, now since the art of printing has been discovered, is sure to be retained; and "these revolutions do not backward." Men after they once become accustomed to read a well conducted agricultural paper are quite sure to keep on; and from being an indulgence becomes a necessity, like a dog whose teeth has once been fleshed in the blood of a sheep, can never be deterred of the appetite, but will be sure afterwards to be found among the flock. We wish we might thus sharpen the appetite of our readers. If an ardent devotee and much pains-taking will make our paper sensible and attractive to them, we shall confidently anticipate upon success.—Ed.

PLAN OF A BARN.

MR. EDITOR.—Not the least among the many advantages to be derived from an agricultural paper to the farming community, is that it may be a medium of information adapted to save time and money, and promote economy and convenience in giving plans of buildings. Such have been given from time to time in your valuable paper; and without further preface, I submit the following plan of a building, which I have found from experience, to be cheap and convenient, and adapted to save much labor every year. The whole is a building 36 ft. by 75, with a basement.

Fig. 1.

Fig. 2.

FIG. 1.—PLAN OF BASEMENT.

- A. Carriage Room, with spouts s s from granary above.
- B. Stable for horses.
- C. Meal and Grain room, with manger between that and stable.
- D. Cellar, which perhaps some would have larger.
- E. Place for sheep to eat.
- F. Cow shed.
- G. Calf shed.
- m. m. Mangers for horses, cows and sheep, communicating with the upper floor.
- s. s. Spouts communicating with granary.
- b. b. Bins for grain and meal.
- Stairs from stable to upper floor, between B. & C.

FIG. 2.—UPPER FLOOR.

- A. The main floor, s. spout to bins below.
- B. Bays.
- C. Floor with scaffold overhead, c. corn crib.
- D. D. Granary with a passage through, a and spouts leading to carriage room below.

It was wisely and justly remarked by Mr. Peters, on page 25, vol. 2, of your paper, that there should be a place for your horses and carriages, harness and grain, and hay, all under one roof if possible, and those who have it differently can hardly know how much time and labor are lost.

Here we have the same as a building 72 ft. by 75,

or as the following buildings, which are necessary for every farmer:

A carriage house 24 by 30 ft., and a horse barn 22 by 36 ft., which, built in the ordinary way, would cost at least	\$300
Sheds for cows, calves and sheep,	200
The same or more than two barns of the common size, 30 and 40,	500
Total	\$1000

The cost of this as nearly as I can estimate it, is about \$500, covered with rough boards, being a saving of \$500 over the common plan, which is worthy of consideration in these times.

But where, says one, is the saving of labor? Besides the saving of labor and time in doing my "chores," which is considerable, I leave in getting out and stacking the straw when threshing, at least two hands per day, besides a great deal of very hard labor in loading grain for market, and in conveying the oats and meal to the bins back of the stable through the spout in the middle floor.

Another item; I generally thresh my grain early in the fall and stack and mow the straw, and this leaves the middle bay for the corn which I draw in when dry and it may be husked in any weather and put in the crib, thus not only saving time but much of the fodder; and the corn can be threshed (as it should be, and ground) ready for the swine.

Yours truly,

P. PARKS.

Victor, N. Y., 1842.

Remarks.—We feel obliged to Mr. Parks for the above communication. He speaks of it as his first attempt. We hope it will not be his last, and that he will let us hear from him as often as his convenience admits of his writing.

We look upon the arrangement and construction of his building as convenient, and combining much in a small space. We think that thirteen feet do not give width enough for a horse stable; it should not be less than fifteen; there will then be room enough to hang up their harness and to pass in safety behind them. We consider seven feet for a sheep house as quite too narrow, though something must depend in regard to all these matters, upon the size of the farm and the amount of stock to be kept. We are much too strongly inclined to give too little room to our animals; and one would suppose from the construction of a large proportion of the barns built fifty years ago, that men were not to be found at that time over five feet and a half in height. We think the cellar in the plan is not half large enough, because every farmer who keeps sheep or neat stock, should always have an abundance of succulent food upon which to feed them, for the storing of which he requires a good barn cellar.

It is difficult from merely looking at a plan upon paper to pronounce with confidence upon its advantages or inconveniences. But we shall be happy to give a variety of plans, such as have been tried, or such as may suggest themselves to reflecting minds, who are endowed with a good constructiveness. We have different wants and very different notions, and very different locations in which to place our buildings, and very different uses to which to apply them. But by presenting a variety of plans and giving the suggestions of different minds, any one disposed to build may follow, select, combine or alter the different arrangements as may suit his own taste and convenience. We have known very few men to build a house or a barn, who were not obliged to confess, when it was completed, that there were some points, were they to build again, in which they should do differently from what they had done.—Ed.

Maine Report on Agriculture

The Report on Agriculture presented at the Agricultural meeting held in the Capitol, in Augusta, Maine, January 24, 1842, and signed by James Bates, Chairman, is given in the Maine Cultivator of January 22d. It is drawn up with signal ability; and in clear and a direct manner points out the most important objects of agricultural inquiry, experiment, and improvement. We subjoin some extracts, and regret that our limits forbid the insertion of the whole.

Although Maine stands unrivalled in its maritime facilities and inexhaustible water power, is rich in minerals and forests, its growth and prosperity must mainly depend upon its agricultural resources; and that to develop these and increase their productiveness are objects worthy of the best effort of its citizens and government.

In bringing forth the productions of the earth, he is the most successful agriculturist who manages and cultivates best. Whether a man cultivates a few acres or few—whether his soil be rich or poor—his precept and example are most important to his community, which makes the greatest improvement of his mind and position. The man who turns a barren plain or bench to a fruitful field, or reclaims a worthless bog, which was before only a nuisance, may do more for himself, and be of more use to his neighborhood, than he who cultivates the largest interval farm in the State. We do not feel sure that there exists a correct public sentiment on this part of the subject; be that as it may, it cannot be concealed, that much diversity of opinion exists as to the best mode of cultivating almost every variety of soil, and the kinds and conditions of manures and modes of applying them; and for want of the necessary information upon this subject, much loss of labor annually results from ill-directed effort. Men must already be in possession of facts of high practical importance; which are either not known or not duly estimated by others; which if spread before the people, would advance the interests of our entire agricultural population. Such men possess the means and information necessary for instituting experiments, which would continually aid and increase such advancement.

In order to avail ourselves of what is already known and to keep pace with improvements which are daily developing themselves, measures are required to diffuse extensively that knowledge which is already possessed by some, and well conducted and judicious experiments are needed to add to what is already known.

They believe the time has arrived when inducements should be held out for well conducted and faithfully recorded experiments.

1st. To test the comparative value of different manures as applied to similar or dissimilar soils.

2. The best mode of manufacturing manures, and the time and manner of applying them.

3. The most profitable crops to be grown on different varieties of soils, having reference to locality, market, &c.

4. The best mode of preparing the soil for, and management of, different crops.

5. The advantages to be derived from admixture of manure by supplying those constituents found to be materially wanting, or in too small proportion. The materials for doing this, existing in abundance in every part of the State. It seems of great importance to ascertain not only the best mode, but the time when, and place where, increased production will compensate the outlay of labor and expense. We doubt not the time is approaching when our sandy plains, stiff clays and stubborn bogs, will, by simple admixture, with the addition of a small quantity of lime or other alkaline substance, be rendered abundantly productive.

6. To test the comparative value of the different grains and roots to be consumed on the farm in feeding and fattening animals.

7. What animals are best suited to our climate, and most profitable in the different sections in the State.

We cannot doubt that such experiments judiciously made and faithfully recorded, would greatly conduce to the public good; and since such experiments would often require a sacrifice of expense and labor on the part of those who make them; we believe sound policy requires that inducements should be offered at the public expense, sufficient to secure the attention and enlist the efforts of those most competent to make and record them.

No mode of doing this, has suggested itself to your committee, which seems so feasible and at the same time so equal, as to offer such inducements through

We regret that the articles on Stearine from Lard, Oil from Corn Meal, and Tomato Figs. &c., from our respected correspondents McLean and Crocker, though in type, are unavoidably postponed to our next number.

Scientific Agriculture. -- Letter IV. -- Manures.

The value of ammoniacal liquor produced from the distillation of coal for gas being fully ascertained it seemed to be desirable to make a composition which besides other actions, should produce the liquor or a good substitute for it, with the additional advantage, that it should, by its very gradual decomposition, supply the ammonia slowly and in small portions at a time. Let us examine how these conditions are fulfilled in this new artificial manure. It is now admitted on all hands, that coal is of vegetable origin; in other words, that it is formed from the dense forests of the primeval ages, buried and carbonized by heat under immense pressure, and also that all vegetable substances contain a small portion of azote or nitrogen. Now sawdust is the basis of this new manure, and wood is the basis of coal, according to Liebig; also vegetable substances when decayed from humus. This sawdust is mixed with carbonaceous matters; what these are I do not pretend exactly to announce. Coal tar, as tar, is certainly injurious to vegetation, yet it may, by some process, be deprived of this property, but nearly all these carbonaceous substances contemplated, except coal ashes and anthracite, contain a certain small quantity of nitrogen. To these are added lime and soda; these two, besides their value in agriculture by themselves, according to recent chemical discoveries, when in combination, are very powerful agents to cause the evolution of ammonia; lime is so by itself. Of the small proportion of sulphur added I will say nothing, except frankly to confess that I do not at present see its value, unless it produces sulphuretted hydrogen or in some way assists the decomposition of the mass. Nevertheless, I should by no means omit it in making the trial.

Here then is an admixture containing many of the most valuable requisites for luxuriant vegetation, which, if its own internal action produces gradual decomposition, must be of much service in agriculture. One thing, however, is still wanting.—proof, extensive proof under many circumstances. That it will be extensively tested with various soils and in various situations, there is no doubt; if successful, it will be another jewel added by science to the agricultural wreath.

Reason and experience teach the undoubted value of nitrogen or azote to plants; let us now see what substances contain this, and how the farmer may procure it in the most economical way, for it is no use to explain to him the value of the gas liquor, when there are no gas works within miles of his farm.

All animal excrement, as cow and horse manure, but particularly that of man, contains a large quantity of ammonia, which is azote mixed with hydrogen gas. On the proper management of the dung heap of his own farm, the farmer has chiefly to depend.

It is now the fashion to say that fresh manure is the most valuable, that is manure previous to fermentation, as it is by this fermentation that much of this important ingredient, ammonia, evaporates into the atmosphere and is lost to the owner, although his neighbor may reap the benefit of it. But the farmer can only manure his land at certain periods of the year; therefore, even if it were best in this state, it cannot always be used fresh. Formerly it was believed that old and well fermented stable dung was the finest and richest manure that could be had, and this is now not far from the truth, although some valuable ingredients are lost, and the quantity appears to be much diminished. Let us reason on the subject with the new lights. Fermentation and heat in the interior of a large dung heap, carbonize the vegetable matters, which are then in the most extreme state of minute division; the particles being much smaller than the finest powdered charcoal, each of these minute particles is thoroughly saturated with the ammo-

nia formed in the centre of the heap, and which was prevented from escaping by the manure outside; these particles are moist and cool and packed together so closely that all further escape is prevented. On the application of these minute well saturated particles to the action of the roots, great insurance results; their contents, both of carbonic acid and ammonia, are absorbed to the plants just as they are wanted, in great plenty, and in a state of the minutest division. But it is true that much ammonia is lost, and what is lost is wasted, and must be saved. Now good loam is found on many farms, and this is an excellent absorbent of ammonia, although not so good as carbon. The intelligent farmer should therefore pay much attention in making up his manure heap, and as he lengthens the ridge by additions, should carefully cover it up with loam, which would thus absorb the ammonia that would otherwise escape, and become so impregnated with it as to form a very valuable addition to the heap. Mr. Schottman in Germany, who has the manure of about 400 horses to manage for his land, in order to save the ammonia from escaping, constantly moistened his heap with green vitriol or sulphate of iron, and as fast as it ran through poured it on again; the sulphuric acid of the vitriol or sulphate of iron catches up the ammonia and forms a sulphate of ammonia, which with oxide of iron or iron rust, remains in the dung heap. I confess I am a little sceptical on the value of this plan, but believe in the superiority of covering up, but it shews at all events that there is a general faith in the value of ammonia. The labor, to say nothing of the vitriol, would be too valuable here, and it is probable that the oxide of iron in any quantity would be injurious to vegetation. All night soil and excrements of man, must be carefully collected and added to the heap, as well as all slaughter house offal, except the fat which is of no value; these contain a very large quantity of ammonia. It is in the careful preservation of these, and no doubt in the useful practical preparation of them, that the Chinese so far excel the rest of the world. The communication of the minute details of the Chinese methods of preparing and applying manures of all kinds, would unquestionably be of the greatest interest to our agriculturists, and it is to be hoped when all the political troubles are gone by, we shall be enabled to get some insight into their practices. These substances, however, require to be used with the greatest caution; all food offered to plants, except in a state of the minutest division, is injurious to them; the Homoeopathic system suits them best, but then it must be given in great plenty and all the time they require it. Thus the ammonia in rain and snow water which, according to Liebig, is absorbed by plants, is in so small a quantity as to have, until within the last few years, escaped the research of chemical analysis; and the value of the well fermented manure mentioned in the former part of this letter, depends much on its minute division. The night soil and offal should therefore be added to the manure heap in small quantities, and spread thinly about, so that its decomposition by the fermenting heap would be surely effected. Green crops also contain ammonia, and must therefore be useful manures. There are, however, several other sources, from whence azote or nitrogen may be readily obtained in abundance. These are the class of salts called nitrates, such as nitrate of potash or saltpetre, and nitrate of soda. Your readers are already informed how extensively these are used in English agriculture, and by the last accounts, the application of them was certainly increasing.

Dumas, in his Treatise on Chemistry, states that 100 pounds of saltpetre contains as much nitrogen as 3 to 400 pounds of animal matter. These nitrates consist of nitric acid and potash and soda, respectively,

and nitric acid contains one part or equivalent of nitrogen and five parts or equivalents of oxygen; and the constituents of these substances then, are necessary to vegetation, and according to the above statement of Dumas, which there is no reason to doubt, the requisites are condensed into a small space. My own experiments with saltpetre, which were not on a very extensive scale, gave a large increase of foliage; but could not observe a corresponding increase of flower or fruit,—this, however, on grass lands would be very advantageous. Yet these nitrates, however, like the former compounds of nitrogen, must be used with much caution, as too large a quantity presented to the roots at once would inevitably destroy them; of this many instances have occurred under my own observation. With respect to saltpetre, it often comes from the East Indies considerably adulterated with common salt, as much as 5 to 12 per cent, sometimes even more, and although salt in small quantities is not injurious, yet it is by no means so valuable as saltpetre it also comes sometimes in large crystals—sometimes drier than at other times. These remarks apply to the quantity per acre; of saltpetre of fair quality about 1 cwt. to the acre, sown broadcast in the spring is considered a proper supply; but if the crystals are large they ought to be broken, as a large lump falling near a plant would prove very injurious on that spot. These remarks are equally applicable to nitrate of soda which, however, seldom comes in such large crystals and is often more damp than saltpetre. Of course the more moisture, the more water, and the less nitrate of soda in the weight, so that it will often be requisite to apply $\frac{1}{2}$ or even $\frac{1}{3}$ cwt. per acre of this latter substance. Another source of nitrogen or azote to plants is rain and snow water. Liebig states that all animal and vegetable substances which decay in the open air, give out ammonia in quantity, that when the rain descends in drops through the atmosphere, it combines with this floating and aeriform ammonia which is thus conveyed to the roots; and that in this way a considerable part of this necessary substance is provided for vegetation. It will have been observed in one of my former letters, that ammonia, although found in almost every part of a vegetable in very small quantity, still does not constitute any considerable part of the plant as does carbon, but that its use is chiefly to assist in the digestion or assimilation of the food which the plant takes up; hence we see the necessity of its being supplied constantly with this food, and in small quantities; in proportion, therefore, to the supply of food, so must be that of nitrogen and ammonia.

J. E. T.

Lectures on Agricultural Chemistry, by Jas. F. W. Johnson, reader of Chemistry and Mineralogy in the University of Dublin, Eng.

This is an excellent work and contains a large quantity of valuable information; but these Lectures ought to have been called Lectures on the Chemistry of Vegetation, rather than on Agricultural Chemistry and this distinction is drawn in order to prevent those who take it up from being disappointed in their expectation, if they think to find it full of ideas and recipes respecting the mixture of composts and the various scientific modes of tillage.

Although very far from wishing in any way to depreciate the value of the great mass of scientific knowledge, of which the rays are now accumulating to concentrate in one brilliant focus of light on agriculture the truth is the numerous recent publications on this subject render it quite clear that before this knowledge can attain its desired practical force, either the farmer must become more of a chemist, or the chemist more of a practical farmer. When this union of character and pursuits shall have taken place, then, and then only, shall we be able to pass just sentence on most of the theories recently put forth by scientific men.

In the mean time it is quite delightful to see with what zeal and energy, with what care and calculation, men of science institute accurate experiments to elucidate particular points, and to extend their knowledge on the subject of agricultural chemistry; and as directing posts to the agriculturist, those experiments are of the greatest importance; but in order to understand them, to draw proper inferences and deductions from them, or to vary the application of their principles to varying circumstances, such as situations, soils, crops, manures, &c., the farmer must brush up his knowledge, must cultivate his mind as well as his field. Let him rest assured that in both cases the crops, in profit and pleasure, will be in proportion to the labor bestowed. The chemical statements and calculations or, as we ought to call them, the chemical statistics in this work, appear to be exposed with much simplicity and accuracy, considerable industry has been likewise expended in drawing information from the latest and most authentic sources of knowledge on the subjects discussed in each lecture.

The first lecture contains an account of the nature and known properties of the four chief ingredients of all the vegetation around us, Carbon, Oxygen, Hydrogen, and Nitrogen or Azote.

The second lecture discusses on the substances organized out of these ingredients, of which the vegetable is composed; and their relative proportions in various plants.

The third explains the properties and relations to vegetable life of carbonic and oxalic acids, and of ammonia.

The fourth gives the probable sources of the ingredients mentioned in the first lecture, with various conclusions drawn.

The fifth, an account of the general structure of plants, with the functions of their leaves, stems, roots, bark, &c., and of the various circumstances by which these functions are modified.

The sixth describes the substances of which plants consist—such as woody fibre, gum, starch, sugar, &c., with their mutual relation and transformations, and considerations on the acids in plants.

The seventh is on the chemical changes which take place during the germination of the seed, development of the leaves, roots, flowers, fruit and seeds, and the circumstances by which they are promoted.

The eighth and last, is on the theories recently propagated of the chief supply of carbon and ammonia to plants from the atmosphere, and on the various means by which carbonic acid and ammonia are constantly supplied to the atmosphere to make good the large quantities constantly abstracted by plants.

Here is also an appendix of 40 pages containing the results of practical experiments in agriculture, with suggestions for experiments.

From this brief analysis of the work, it will be seen that the information it contains is of a varied character, and it certainly offers to notice many facts which deserve to be deeply studied by every agriculturist. In pages 146 and 147, there is a very singular result given as of frequent occurrence in Holstein—it is, that in contiguous fields, some of which are manured with man and some left unmanured with man, the crops in the unmanured fields are worse than if the whole fields had been left unmanured, which is just like saying that the healthy crops on the manured lands appropriate to themselves a larger portion of the nourishment from the atmosphere of the unmanured (carbonic acid and ammonia), while the weak crops of the unmanured fields are obliged to put up with the smaller quantity left by the others, for their support. If this be true, and we see no reason to doubt it, as it corresponds with theory, then the farmer who manures his land well and keeps it in good heart, obtains from the atmosphere a large portion of the nourishment contained in it, which

would have gone to his neighbor's crop had it been equally well manured. It is hardly possible to imagine a fact more calculated to give rise to emulation in manuring land than this, and the most delicate conscience could hardly find it an injustice to appropriate to itself the carbonic acid and ammonia of its neighbor's atmosphere, by highly manuring the land. How vastly puzzling to the lawyers, were the farmers to bring actions at law against their neighbors for the abstraction in this way of the atmosphere on their different farms!

In this work there are many confirmations of the truth of facts strongly insisted upon by Liebig, particularly that of the existence of ammonia in almost all vegetables, and the probability that much of it must have found its way there from the ammonia of rain and snow water, although not to the extent supposed by Liebig; for Mr. Johnston states in his last lecture that much of the ammonia combined with rain and snow water, must find its way in its natural descent, as well as by means of rivers, to the sea, and there be engulfed,—there being, as he states, no process by which this ammonia can be restored to the atmosphere. In this point, however, he is in error, or probably he has not heard of the experiments of Mr. Aime, Professor of Physics in the French College at Algiers, which proved that large quantities of gas were disengaged by marine plants (sea weed) from the salt water, which gas contained from 15 to 83 per cent of Nitrogen and the remainder Oxygen—the percentage of nitrogen depending on the time of the day when the gas was disengaged, the bubbles of gas disengaged before sunrise containing the largest quantity, those after sunset the smallest; several new facts are also added to our knowledge, such as that the hydrogen of the ammonia is useful to the growth of vegetation.

The accounts in the Appendix of the experiments with various substances used as manures, such as sulphuric acid, gypsum, saltpetre, nitrate of soda, sulphate of soda, charcoal, salt, ammoniacal liquor, &c., &c., are of the greatest interest, and should be spread among farmers through the different agricultural periodicals in the greatest profusion. But they ought to be accompanied with remarks on the condition of these experiments, many of which seem altogether to have escaped the notice of the experimenters. Thus a soil of stiff loam holds moisture and ammonia with much more tenacity than a sandy dry soil: hence in the latter, any solutions of ammoniacal liquors, or nitrates, or other substances, require to be applied in a weaker state and much oftener than in the former. It must also, not be forgotten, that the solution of ammonia which nature presents to plants in the form of rain and snow water, is in so weak a state that our chemical tests will hardly discover it—and that if this ammonia is given in strong solutions it is more likely to injure than benefit the crops. Now all ammoniacal liquors from gas works are of varying and uncertain strength: therefore, unless this strength were known pretty nearly, the result of the experiment would hardly be a fair guide for others. The strength of various applications is an object of the greatest importance in experiments, as is also the nature of the soil and the kind of crop. Another remark may also be of service. The saltpetre imported from the East Indies is usually adulterated with a mixture of common salt, from 5 to 20 per cent, and also with sulphate of potash. Now in experiments the refined saltpetre should either be used which is free from these admixtures, or the saltpetre, if used as imported, should be analysed to ascertain the quantity of them. The nitrate of soda is probably less liable to these adulterations. In the appendix are also many suggestions for experiments, which are of considerable value. Altogether, it is a work well worthy the study of the practical agriculturist, and if there are many parts of it which he cannot at first understand, this study will elevate his ideas on the subject, and enable

that desire for knowledge in his mind which will urge him forward in acquiring it, until those parts which at first puzzle and confound, will appear to him quite simple and clear. It is a great advantage to the agriculturist in reading such works, that he lives surrounded by the means of testing its principles, that such operations are his daily occupations and the observation on them is daily before him; so that if he employs well his powers, but a season or two can elapse before he himself will be a better judge of what is there laid down than the writer of the book himself. J. E. T.

Care of Apple Trees.

Mr. Emory—Traveling through the United States, in 1840, '41 and '42, I observed the apple trees were become very scrubbed, and many of the apples inferior in size and flavor. The inhabitants ascribed these effects to the apple tree worm. I believe they are all mistaken. Why do they not destroy the worms; it is very easy to be done. Lime water, or strong soap suds, thrown on them will give them a quietus. I am, however, certain the defect is owing to no other cause than lopping the trees in the month of March and April. Let them alone until after they are out of blossom, and then from that time, until the leaves fall, trim and lop them. If you are doubtful of the good effect of this treatment, try one or two of the worst trees in your orchard, and you will see a great change in them in less than two years. Instead of putting out suckers, as it is generally called, the trees will grow smooth and thrifty, and the fruit become smooth and fine, with a great increase in size and flavor. I have tried the experiment, and found it to succeed beyond my expectations. The best manner I ever found for an orchard is to draw fresh earth from a distance and throw a few shovels full carelessly near the root of the trees, but not to touch the trunk.

If you think this hint worth a place in your useful paper, perhaps some one besides myself may try the experiment. Apples are deemed by many a worthless crop since the temperance societies have been established. As cider is going out of fashion, try how your horses, cows, and swine will relish a feed of those sorts you used to grind up for cider. Apple trees in general, produce the greatest profit for the labor, of any crop produced on a farm, and if well attended, will pay 50 per cent clear gain, on all outlays.

B. K. DODGE.

Premiums for Wool Shearing.

In England, Sheep Shearings are made the subject of spirited competition and premium. This is a capital plan. Premiums are awarded to those, who perform the work of shearing in the best manner, and in the shortest time; and also do up the fleece in the neatest and best style. Five sheep in general constitute a trial for one adult person. Three sheep to boys between 14 and 16 years old. Two sheep to boys under 14 years old. The highest premium noticed is £3 stg.—the lowest £1 stg.—but a gratuity is bestowed upon the unsuccessful competitors. This would be an excellent subject of competition with a farmer's club in the same town, or one made up of several towns in the vicinity of each other; and now grog money has ceased to be demanded, it would not be difficult to make up a purse. After the play the farmers dine together. This is always, in such cases, a comfortable and desirable accompaniment, where the expense is within the reach of the humblest individual.

SNAKES.

Those who are in the habit of destroying snakes, had better let them alone for a few years, as they are early risers, and generally at work in our field by the break of day, picking up those little depredators, the corn worms, which any person may see by going into the corn fields as early, and may satisfy themselves. B. K. D.

Transactions of New York Agricultural Society.

We are indebted to the politeness of our friend Luther Tucker, of the Albany Cultivator, for "The Transactions of the New York Agricultural Society, published by order of the Legislature." The volume has been got up under the superintendence of the Recording Secretary of the Society, Henry S. Randall, of Cortlandville, and does great credit to his intelligence and good judgment. It contains a large amount of highly valuable matter, and may be considered as an important step in the advancement of a Society destined, from its position, the zeal which gives it impulse, and the intelligence which it combines, to exert an efficient influence upon the agriculture of the whole country.

The volume will be extensively circulated through the State, but as many of our readers can scarcely expect to become acquainted with it excepting through our columns, we propose to go through the book, making such selections and notices as we deem interesting and bearing most strongly upon practice.

To the honor of New York, she has not been backward in giving to the country several valuable publications on the subject of Agriculture. We regret that in this case we cannot refer to dates, but they are not material in relation to the facts. She early instituted an Agricultural Society, which, under the care of Chancellor Livingston and M. L. Hommedieu, and other eminent coadjutors, gave four valuable quarto volumes to the public, containing discussions and information in relation to several important subjects of agricultural inquiry and experiment. Her Legislature afterwards, under the direction of Mr. Featherstonhaugh and Mr. Buel, published three octavo volumes of agricultural essays and communications, which we have always regarded as among the very best papers ever given to the country. In the mean time, one of her distinguished citizens gave the public an important treatise on the Management of Sheep, mainly translated from the French; and another, a Treatise on the whole subject of Agriculture, which, for the amount of useful information, compressed into a small space, is surpassed by no book within our knowledge.

The Albany County Agricultural Society about this time likewise published several useful tracts; but their publications were soon interrupted, for reasons of which we are not apprised. Then came along the Plough Boy, printed at Albany, which we have had no opportunity of examining, but which we believe was mainly intended for a Farmers' paper. To this succeeded the Genesee Farmer, edited by Luther Tucker; and after that the Albany Cultivator, under the care of Judge Buel, and since his lamented death transferred to the very able editorship of Messrs. Tucker and Gaylord. It may be said with no disparagement to any other publications in the country, that more intelligent, useful, and able periodicals than these two papers have been, and the latter continues to be, have, so far as our knowledge extends, been produced in no country. At the demise of the Genesee Farmer by the removal of its principal editor and publisher to Albany, the New Genesee Farmer made its appearance at Rochester, and for two years the strong approbation with which it was received, evinced the ability with which it was conducted. Now, in its third volume, having passed into the hands of a particular acquaintance and friend of ours, we feel some reluctance in saying what we think about it; but we may be allowed to add that we hope something from the lad's industry and good will in the cause.

In the city of New York at the same time were published the New York Farmer, edited by Samuel Fleet, and the New York Quarterly Farmers' and Mechan-

ics Magazine, which latter proceeded to four volumes octavo, but was in the main a reprint of the former; both of them full of valuable information and useful suggestions and essays.

This has been followed by the Farmers' Library, a republication of several valuable foreign works, in monthly numbers, by Mr. Fleet. The Silk Worm, likewise, devoted to the Silk Culture, and published at Albany, reached several numbers under the editorship of Mr. Blydenburgh.

The Journal of the American Institute, under the care of Mr. Wakeman of New York City, gave many of its monthly pages to agriculture.

The Central New York Farmer, under the able editorship of Mr. Johnson, and published monthly at Rome, N. Y., and the United States Farmer and Journal of the American Institute, opened with the present year, and are doing good service to the cause.

A new conditor is now added to the great cause in the American Agriculturist, of which we have been favored with the April number, published monthly in New York City, 16 pages octavo, at one dollar per year, edited by A. B. & R. L. Allen; and promising from what we have seen, efficient and intelligent aid to the improvement of our Live Stock in particular, and the general interests of an Improved Husbandry. We most heartily wish their success.

In addition to these, Messrs. Wiley & Putnam of New York, bookseller and publishers, have issued several highly valuable publications on Agriculture and Horticulture, and design to keep the press warm.

In the production, therefore, of agricultural information and knowledge, New York may justly lay claim to the credit of having contributed no inferior share. We trust she will continue to go on in this important career every year with increased spirit and intelligence. Agriculture is her great interest; here her resources are immense; and we had almost said it may require centuries fully to develop them. Every forward step in the subjugation of her uncultivated territory, in the improvement of that which is already subdued, and in the increase of her productive powers, must essentially advance her prosperity, her wealth, her independence, and, above all, the general comfort of her rapidly increasing population.

The volume commences with a general history of the New York State Agricultural Society; the Cattle Show and Fair at Syracuse, and the proceedings of the Society at its annual winter meeting in Albany, with the address of Mr. Nott, the President of the Society, on that occasion. These have been already given to the public through our own columns and those of the Cultivator.

These are followed by the Reports of several of the County Societies, of their condition, prospects, and the use they made of their funds and the bounty of the State. Societies were organized in thirty-two of the counties of the State, but only nine have made returns of their proceedings, and these returns are very partial and imperfect.

Tompkins County.—From the return of the Society of the County of Tompkins, reports are given on the subject of Live Stock and the cultivation of Corn and Beets.

The report on Live Stock highly approves the Improved Durham Short Horn. For size and symmetry, for early maturity and an aptitude to take on flesh of the best quality, as well as their production in milk, the committee pronounce decisively upon their superiority; but they have some hesitation in recommending them for oxen.

From the style of this report we are inclined to regard it not so much the result of actual observation and personal experience, as of general and popular impression. We have seen only one yoke of pure full bloods, but we have seen several pair of half bloods,

which were powerful, quick, and perfectly well trained, and we know no reason why they should not make as good oxen as any.

The committee proceed to denounce the Yorkshire breed, by some persons mistaken for the Durham, as a race by no means to be esteemed. They fat poorly; do not follow well; their meat is not good and they are bad milkers.

In some parts of the country this kind of stock remains; but they are not approved. The farmers in Tompkins are certainly not alone in this decision.

Crops.—Four crops of corn are reported to have been presented for premium. Three kinds are mentioned as having been cultivated.

The Dutch, planted in hills four feet apart each way gave 113 bushels of corn and three tons of fodder to the acre.

The Brown Corn produced 105 bushels of corn and two tons of fodder.

The China Tree Corn produced 90 bushels of corn and four tons of fodder.

The Brown Corn, but for some mismanagement, it was thought would have produced the largest crop. The China Tree Corn is pronounced too late for our climate. The mode of harvesting was by cutting up and stacking, when sufficiently glazed.

A second account is given of producing 92 bushels of corn per acre.

This was on a clover lay manured the previous season. The account of cultivating this acre is thus stated:

92½ bushels of corn at 50 cents,	39,25
Two loads of stalks at 2 dollars,	4,00
	<hr/> 50,25
Expense of cultivation,	14,05
Use of land, profit, &c. &c.	<hr/> \$36,20

Sugar Beets.

One plot of ¼ acre yielded at the rate of 790 bushels per acre.

On plot of ¼ acre yielded at the rate of 596 bushels per acre.

One plot of ¼ acre yielded at the rate of 502 bushels per acre.

Orange County.—The Report of the Orange County Agricultural Society is only remarkable for Mr. Bull's account of his method of raising calves. This is certainly high authority, as who should know better than he?

The Orleans County Agricultural Society report a premium on a crop of Corn of 112 bushels and 30 quarts per acre:

And of potatoes of 700 bushels per acre.

The potatoes were planted upon a low piece of "rich mucky ground never before planted, and had been used for a hog pasture two years previously." The potatoes were planted "close together one way and about two feet and a half the other." This account is not remarkably definite, and the mode of measuring is not given; this we should have been glad to have known.

The corn succeeded corn on the same land; and the preparation was merely splitting the hills of the preceding crop and turning a buck farrow and planting in the ridge. No manure was put on the land. "It was a lowish piece of ground inclining to muck. Two bushels of plaster were used upon it." We should here likewise have been glad to know how the amount of yield was determined, at what season it was ascertained, and in what mode the plaster was applied.

BUTTER.—To these statements is subjoined an account of a mode of making butter, which being thus presented by the Society, we infer is approved by them. They state "that milk set in wooden keels or tubs will probably yield the most cream, but not the

sweetest." Why it should yield more cream than in tin pans we shall certainly undertake to give no reason, until we know the fact, which at present we distrust. The sweetness of the cream will depend, we believe, upon the dairy milk, upon plenty of water among the pans, and somewhat upon the use she makes of her elbow-joints. He advises to take three-fourths of an ounce of good loaf sugar to a pound of butter—this we utterly protest against. The butter is injured by the application of any thing but the purest salt.

The contributions for premium in Oneida county are highly liberal, amounting to 678 dollars—from the state \$255—from subscriptions \$423.

Niagara County Society. Indian Corn.—A premium on a crop of corn of 103 bushels 44 pounds to the acre, and for a crop of oats of 92½ bushels per acre. No account is given of the mode of cultivation; but we have another account of a premium crop of corn of 71 bushels per acre and six hundred pumpkins on the same land. We think it quite too late in the day to give a premium on 71 bushels of corn, unless there is something peculiar or extraordinary in the cultivation. We should be glad to know the opinions of farmers on the expediency of cultivating either pumpkins or turnips with corn.

Washington County Agricultural Society takes the lead of all others in regard to crops; and announces the largest crop of corn ever recorded in the country within our knowledge.

Job Eldridge produced 132 baskets of corn on an acre, each basket 15-32 bushels strict measure, which if there be no error in our reckoning, would be equal to 173 bushels 6 quarts to an acre. This statement will be received, we apprehend, with some incredulity; and we can only express the wish that it had been more fully certified. We do not deny its possibility, for we have not reached the end of our line yet; but, but, but,—we should like to have done it, or to have seen it done.

To Peleg Sherman likewise was awarded a premium for 896½ bushels of potatoes on an acre. This was a magnificent crop; but the committee are careful to express in a note their chagrin at the imperfect manner in which the amount of crop was verified. The mode of measuring, that in finding that six hills would make a bushel, and then counting the number of hills on the acre, is altogether uncertain and objectionable. We should be very glad to know how they arrived in the case by such a mode, to the fractional excessness of two thirds of a bushel.

We do not, however, deem the statement absolutely incredible, as we have the assurance of one of the best farmers and best men in the country, that he assisted in the cultivation and harvesting of 4000 bushels of potatoes from five acres of land.

Eight premium crops are mentioned in this case, but with the exception of Mr. Sherman's statement in a note, no account whatever is given of the modes of cultivation. To know how a thing may be done seems in these cases to be much more important than the simple fact that it has been done.

We shall pursue the examination of these papers on a future occasion.

Wool Growing.

The subjoined article is from the Boston Cultivator of June 4th, whose editor, H. G. Meriam, whether his views be right or wrong, is entitled to the highest credit for the ability and zeal with which he advocates what he deems the best interests of the Farmer. We are not prepared to enter upon this subject at this time, but the facts which are stated here certainly deserve the most serious consideration. It is obvious how difficult it must be under any protective system, to adjust harmoniously and satisfactorily all the diver-

sified and conflicting interests, where, in respect to many of them, one can live only by eating up an other.

Facts which have recently come to our knowledge, make it our duty to call the attention of the public and our legislators to the condition and prospects of our wool growers. Wool growing has already become a great business in the United States, millions of capital are already invested, the resources of this vast country, especially the far west, have not as yet begun to be developed in Sheep-busbandry—though our annual wool product now exceeds fifty million pounds, and has been worth about \$20,000,000. The number of Sheep in Vermont exceeds thirteen hundred thousand—in New York, five millions three hundred thousand—in Pennsylvania, three millions three hundred thousand, and in Virginia, twelve hundred thousand, and in Ohio, nineteen hundred thousand.

Now what are the prospects of this vast and growing business of the country? It is evident to every man of sense, that the whole depends upon an adequate market. We have before said, that the wool growing business was already nearly ruined by the importation of foreign wool admitted duty free, such as come in competition in our own market, with our wool of a medium quality. In this we were grossly deceived—we should have said such as come in direct competition with our wool of every quality.

We have before us now on our table, six kinds of wool, imported duty free, from South America, finished in samples by one of the largest importers in the United States, which actually cost in South America from 3½ to less than 8 cents per pound, and therefore all admitted duty free.

The 1st kind is a long coarse wool about 7 inches in length, and about as fine as the wool of our coarse long wool sheep, and such as is manufactured into carpets, worsted, coarse blankets and negro clothes—and comes in direct competition in our market with the wool of our Bakewell and other coarse long wool sheep. This sample is very white and clean and may be afforded for 12½ to 16 cents per pound.

The 2d kind is a coarse wool of a finer grade, full as good as the wool of the best of our old fashioned common sheep, and is admirably adapted for a middle grade of broadcloths, cassimeres, woollens, and common blankets. 1200 bales of this wool were imported into the port of Boston, last week, duty free. If this wool be sold at 16½ cents per pound, it will afford the importer over one hundred per cent. profit. This wool by comparison is full as fine as the wool we took from a half Dibley and half Irish corset ewe but quite so long, and may be made as white as the driven snow, by washing alone, as we know by actual experiment.

The 3d is full as fine as our best half blooded merino wool, and may be cleaned, as the importer told us, from 1½ to two cents per pound, either by hand or machinery. This wool is good enough for the second grade of broadcloths, cassimeres, flannels, and the first class of suitings, and may be imported so that it will not cost the manufacturer, when perfectly cleaned, twenty cents per pound.

The 4th, same grade, full of burrs and dirt, may be cleaned for two cents per pound, and may be purchased abroad at the lowest rate above stated.

The 5th, is a sample of wool of about the same grade as the above, short and fine, cleaned in South America, very white and clean. We were surprised when the importer assured us, that this very wool was imported duty free, and cost in South America, positively less than 8 cents per pound.

The 6th is very similar to pure merino wool, and the sample which we have washed in hot soap suds, has become beautifully white and clean. This wool compares well with some samples we have from the Hon. Isaac C. Bates' flock, and others of the western part of this State. So fine was this wool, that when compared with Mr. Bates' wool, we were unable to decide which was the finest, and so we called in a third person, who declared Mr. Bates' a little the finest, but the difference was trifling. This wool was imported duty free, while the very cloths manufactured from this wool, by the compromise act, have been protected by a duty ranging from 50 to 21½ per cent, down to June 1842. Is this the justice our public men render unto the farmer? If so, tell us what you will call injustice.

Our annual product of wool is just about equal to our annual consumption, and under a just tariff giving the farmer an equal protection with the manufacturer, sheep husbandry would expend equally with our manufactures, and the farmer grow rich equally fast.

Much of South America is very favorable to sheep husbandry. One hundred sheep may be raised there

as cheap and easy as ten in New England. They may graze the year round in cheap pastures, and are consequently less subject to disease, and seldom die except from severe storms and old age. Aware of these facts, enterprising men from New England and other parts of the world have gone out to South America, and engaged largely in wool-growing, and who, by judicious crossings, have produced the fine wool of which we have spoken.

These facts have led us to alter our views in relation to the amount of duty proposed to be put on this wool *imported duty free*. The Hon. Isaac C. Bates' wool, being the clip of 1841, is now stored and unsold in the city of Boston, and if we are correctly informed, cannot now command an offer of one half so much as it sold for four or five years ago, so great has been the improvement and increase of South American wool, and the facilities for cleaning it. The twenty per cent duty proposed by the Secretary of the Treasury, on these wools, purchased at less than eight cents per pound abroad, will not save our wool growing farmers from absolute destruction and ruin, and cannot fail to prostrate this department of agriculture throughout the United States. For what does 20 per cent on wool, which costs in South America 5 cents per pound, amount to, as a protection of our wool growers, against this immense and now ruinous competition. One dollar on 100 pounds—just nothing.

The Secretary of the Treasury is certainly mistaken, when he estimates the annual amount of this wool imported, at 9,303,992 pounds, for there was imported into the port of Boston alone, in 1841, by an actual account, which we obtained from the vigilant collector, 6,558,957 pounds, and are assured by an extensive importer, who is thoroughly acquainted with this whole subject, and the amount of importations in New York, Boston, Philadelphia and Baltimore; and he says there is as much imported into New York as Boston, and that the annual and increasing importation, is from 15 to 17,000,000 pounds per annum. This accounts for the great glut and falling of prices in the wool market.

That this subject may be understood at Washington, we shall send on a card containing each kind of wool of which we have spoken, also the sample, which we were told was from one of the fleeces of the Hon. Isaac C. Bates' flock—one sample from Mr. Strong's flock, to some Hon. Senator, with a particular request that he shall exhibit it to his colleagues, and thus we shall soon know who there are the worthy of the votes of farmers, or true to the great and leading interests of the whole people.

Baltimore Wool.

Transactions in wool to a considerable extent have taken place during the week, among which we note a sale of 10,000 pounds Saxony and Merino fleeces, cleaned, at 26 cents, 6 months. Sales also of three quarters to full blooded Merino at 33 cents on time, and of unwashed at 16 to 18 cents. We note sales also of washed Native to quarter blood Merino, at 20 to 28 cents, as in quality.

Productive Sheep.

A black full ewe, sixteen years of age, the property of Mr. Tyson, of the Old King's Head Inn, Broughton in Furness, has within the last fourteen years reared and reared no fewer than twenty-nine lambs! namely, one when two years old, and each succeeding year since.—*Eng. paper.*

Large Fleeces.

Two fleeces of wool shorn this year from Merino Bucks owned by Jesse Harron, Ogden, Monroe Co., of two year's growth, weighed together 23½ lbs 13 oz.

One fleece from a Merino Buck owned by Mills Landon of the same place, of one year's growth, weighed ten pounds.

The above wool was of fine quality, washed and neatly done up.

NEW YORK MARKET, Saturday, June 25.

FLOUR—A sale of 500 bbls good brand Genesee, was made at \$5.57½. Shipers are willing to take large lots at that rate, but cannot find them. The East demand is limited. W. quote Genesee \$5.57½ a 54; Ohio flint, 5.57½; round Michigan 5.57½; Troy 5.57½ a 6. A sale of six flat-bump from store was made at 5½. Southern is very inactive.

GRAIN—The market is very sensibly supplied, and is consequently dull. Small sales Northern wheat at 2-2½ cents, measure, and New Orleans at 55, weight. Oats 39 a 40c. Rye scarce; none sold.

CINCINNATI, June 20—Business in the produce market remains dull—produce of all kinds very low. Pork sells for \$8-10 a \$7 per barrel—Flour \$3.75 a \$3.75 1-2—Wheat 13c per gallon. No sales of note for the past week.

Threshing Machines.

We give below the opinions and experience of two respectable farmers on the subject of Threshing Machines; and we add to this an account of a Threshing Machine invented and used in New Hampshire, from a correspondent who has no pecuniary interest in the machine, and whose statements may be relied on. We regret that it is not in our power to refer to the Family Visitor as he suggests, and we much wish that we were able to give a drawing of the machine.

We have an entire sympathy in the views of Y. in regard to the trouble and inconvenience of having a travelling machine brought to the farm; and we cannot discover much error in the calculation of F. We are not, however, disposed to go back to the old method of threshing by flail; at least where any considerable quantity of wheat is grown.

With Y. we recommend to farmers to purchase among themselves a machine for their own use, and to help each other; or as the current term is, "change works." We are not prepared to say what is the best machine or horse power. With Lane's patent horse power, where the horse moves in a box on iron rounds upon an endless chain, we were not well satisfied. It was not always easy to find a horse that would go in it; and we had frequent accidents both to the horse and the machine. Of Pitts' machine we thought well, though we should prefer to have the two operations of threshing and cleaning the grain, performed separately. Page's (of Keene, N. H.) horse-power is an improvement upon Lane's, as the horse goes upon wooden "treddles." Of the two machines recommended by our correspondent Y., we know nothing beyond his account. A machine, including horse power and threshing machine, is made in Hilledale, in the eastern part of this state, which is afforded for 75 dollars, and which, with four men and a boy, and a yoke of oxen and a horse, or two horses, will thresh one hundred bushels of wheat per day. This is an excellent machine, easily set up and transported from one place to another; but the particular name by which it is designated we could not learn. It is much used and approved in that neighborhood, and by the farmers in the parts of Massachusetts adjoining. The machine referred to by Mr. Lyford, is certainly remarkable for its small cost. We have seen a machine for threshing capable of being transported in a one horse wagon, and the cost of which was comparatively small, by which two men, it was confidently stated, could thresh fifty bushels per day. We saw it in operation, and we know no reason to doubt its efficiency. This was afforded at a low price.

The evil of getting out our wheat all at once, or immediately upon harvesting, does not appear to us so objectionable as to our correspondent F. Because it is threshed and cleaned, it is not necessary that it should be marketed immediately, where a farmer has proper arrangements for storing it. But it is very desirable always to close up such accounts as early as may be, and at least to have the article in a condition to take advantage of a demand as soon as it exists. The objection that the use of threshing machines deprives the poor of employment, is of that kind, which would at once put a stop to the use of any and every labor saving machine whatever.

For the New Genesee Farmer

Threshing Machines.

MR. COLMAN—Having for many years been interested in the Foundry business, my attention was necessarily brought to the various inventions for threshing grain; and since I have commenced farming, I have become convinced that the system now obtaining generally throughout the country, is radically wrong. The system I speak of is the employment of traveling machines, whose owners travel the country and thresh

at a certain price per bushel. It is attended with so many difficulties, troubles and vexations, that it should be exploded in all the wheat growing regions.

Permit me to enumerate some of which, that in my brief experience, appear like a fearful catalogue.

When you are ready to have your grain threshed you are dependent on the pleasure, engagements and location of some machine, which travels in your district of country, and which, like bad weather, comes when it gets ready; or when your turn comes, or when it has finished all of its large and profitable jobs. When the machine arrives, as their interest is to perform the work in the least possible time, you must be prepared with from 12 to 14 hands, the machine must be driven with at least six horses, and such a hurricane of hurry and confusion commences, that it is impossible to do justice to your work. To expedite business, the machine is left to run so open between the cylinder and concave, that the grain is passed through in cart loads, and is not half threshed; and it is impossible to clear and dispose of the straw in a clean and proper manner.

If some part of the machine fails, as is not an uncommon occurrence, your whole army of hired men and teams are idle on your hands until it is repaired, overrunning your garden, orchard and meadow patch, as they are generally a wild set, and what is worse, will rarely work without a plentiful supply of the fire water, unless they know you are conscientiously pledged against this pernicious practice.

If you have a lot of oats, spring wheat, or barley, that cannot be threshed on the same floor, at the same time, it is evident that the flying dragon cannot wait for the cleaning up of the floor, and they cannot afford to come back again without the lot to be threshed is sufficient to pay for the trouble and labor of moving and setting up the machine; consequently, you must hammer it out with the flail, which, in these labor saving times, is not to be thought of.

I have given you the *bare* of this practice, now for the *antidote*. Every farmer should own his own machine, or let two or three join in the ownership. In my humble opinion, the great desideratum would be a *two horse power*. Why—because every farmer has two horses, but every one has not four, and every farmer has men and boys enough about him to work it. Then, sir, he can with his own machine, his own team, his own hands, and at his own convenient time, do his work to his own satisfaction.

The machinery is consequently light and portable, so that if he has a small lot of spring wheat, late oats, peas or barley, for which he has no convenient place to house them in, why he can bring his machine to the barn and dispose of them at once; or if he wants some seed wheat, and has not time to get out his whole crop, or if oats are high priced as they often are just before the new crop comes to market, why he can rattle out his whole crop in one day. Can he realize any of these conveniences from the travelling machines?

The machine being a light affair, it can easily be brought into the wood yard, a buzz saw rigged to it for cutting the winter's wood, or be attached to a straw cutter, grindstone, root cutter, or grain crusher.

Such a machine, with six men and boys and two horses, will conveniently thresh from 75 to 100 bushels of wheat in a day, and should cost about 100 dollars. It should be simple and compact in its construction; the threshing should not occupy more space than an ordinary grindstone with its frame, and the length of the cylinder from 20 to 24 inches and 16 inches in diameter. The length of the cylinder regulates the amount of power or the number of horses required to drive it.

Almost any of the horse powers now in use may be

used successfully with two horses, if the length of cylinder is reduced.

The only machines that I am acquainted with that comes within these requirements, are one made by Ackley of Rochester, and one by Douglass of Skaneateles, who is the original inventor of the *spike machine*; both machines have the strength to stand the power of four horses; but from their lightness and compactness of form, are peculiarly adapted to the two horse threshing. The Ackley machine costs little more than the other, and is of the best workmanship. They are both on the *sun and planet wheel* principle, and work with great ease and safety. Y.

FRIEND COLMAN—I wish to say a few words to the farmers, through the medium of the 'Farmer,' upon the use of threshing machines. Much has been said and many have supposed that threshing machine have been a great benefit to farmers; that they have not, it is my intention to show. First, threshing machines have been a great disadvantage to laboring people. In many places poor people now have no employment in the winter months, and to farmers themselves it is of no advantage. The majority of farmers do not calculate to raise over 300 bushels of wheat annually. This may be set down as an average quantity. To thresh this amount, including the setting up and taking down the machine, takes at least two days, with from four to six horses and ten hands. Two of the horses and two hands, are usually found with the machine. The hire of the other horses, together with the owners of them, two days, may be set down at \$3, pay of the other seven hands two days at 75 cents per day, \$5.25, add to this the use of the machine, at five cents per bushel, (the usual price) on 300 bushels, \$15, making \$23.25. I will now estimate the cost of threshing 300 bushels by hand. A common thrasher will, during the winter months, thresh eight bushels per day. This, at fifty cents per day, the probable price of labor during the winter months, will be \$18.75. Leaving a balance of \$4.50 in favor of threshing by hand. A still greater objection to them is, that it crushes farmers' thresh their wheat all at once and send it to market, thus filling the market beyond the demand and depressing the prices. Such has been the case for the last few years, consequently the price of wheat has been low and little return for it.

Yours, &c.

Greece, N. Y., 1841.

MR. H. COLMAN—At your request I now give you a description of Hubbard's Horse Power and Threshing Machine.

The horse power consists of a light wheel, usually 4 feet in diameter, connected with a shaft 7½ feet long or long enough to permit a horse to pass under it, having an iron gudgeon in each end. The shaft is set up, varying from perpendicular to 20 degrees, to accommodate the band running from the wheel to the thrasher, which may be set higher or lower than the wheel, as the case may require. The wheel is near the top end of the shaft. The gudgeon at the top end of the shaft, runs in a box at the junction of two braces made of light poles, and having their opposite ends, when the power is in operation, fastened with screws to the posts of the barn doors, or any other posts or timbers set up for the occasion. The lower gudgeon runs in a box in a small sill made fast to the ground. On the same shaft and 2½ feet from the lower end, is placed a pulley deeply grooved, 16 inches diameter in the bottom of the groove. Thirty five yards from the foot of the shaft there is placed a pulley horizontally on an iron spindle placed in the ground, (a common iron bar usually answers the purpose,) braced at the top. The power is then put in operation by placing a band round these two pulleys drawn suff-

ciently tight to operate. For this purpose a rope 1½ inches in diameter is ordinarily used. Any number of horses may be attached to this band, to draw in a straight line the length of the band and turning short round the pulleys.

Attached to the threshers is a speed wheel 18 or 20 inches in diameter, from which a belt is run on the cylinder pulley. A small grooved pulley connects with the speed wheel and receives the band from the main wheel at the top of the shaft.

The cylinder is turned from 1500 to 2000 times in a minute, and with force sufficient to thresh a bushel of wheat in less than three minutes with one horse.

Two cylinders of the threshers used is about 24 inches in diameter, and about two feet long.

This machine costs from \$35 to \$40, and in operation and construction is very simple. There is no doubt but, with good attention, it will with one horse power weighing 1200 pounds, thresh 100 bushels of wheat in 10 hours.

I have attempted to give such a description of the horse power as that you may understand it. I have no doubt it is just the thing for the wheat growers of the west.

There is an account of the use of this machine in Hill's Monthly Visitor for June, 1841, and from my acquaintance with quite a number of the men who there certify, I have the fullest confidence in their statements. Yours respectfully,

S. C. LYFORD.

Meredith, N. H., April, 1842.

Manure for Potatoes.

Woolen rags are an excellent manure for potatoes. The rags are cut up in small pieces and put under the sets at planting; and the effect produced is wonderful. It is a long time since I planted any in this way, nor did I ever at the time make any particular observation as to the quantity produced; but this I can say, that they far exceeded those that were manured in the usual way. It might heighten the effect if the rags were dipped in, or saturated with ammoniacal gas liquor; at least it might be interesting to make the trial.—*Gardener's Chronicle for April 16th.*

CULTURE OF POTATOES.—The cultivation of potatoes being considered of great importance, whether relating to increase of quantity or improvement of quality, I would submit a method of culture, which may be new, and which I have for some years found to succeed with a second early kind. Of the potatoes to be planted I destroy all the eyes except one or two with a hot iron. I set them whole, and at the distance between the rows 2½ feet, and 12 or 14 inches apart. The produce has generally been 60 to 70 well formed potatoes, instead of 30 from those planted in the usual manner. Mine had the same management and quantity of manure generally need. E.

[Gardener's Chronicle for April 16th.]

We have read the above with some little surprise. We cannot say that it may not be true, nor have we any objection to our friends boiling their seed, if they think it would do better.

From the New Genesee Farmer,

On Rearing Calves.

MR. COLMAN—Having seen occasionally a hint in regard to the rearing of calves, and also recently a call for some remarks on the subject, I offer the following suggestions as the most economical and convenient, and consequently the best mode that I have adopted.

As soon as the cow has calved, she is milked clean and suckled to remain with her calf for the space of about 12 hours or to the next milking time, when she is again stripped out clean and shut away from her calf until the next milking time. She is then partially milked, leaving enough for the calf, but not so

much as to satisfy him without his sucking the cow entirely of an, so as to bring down the bag and prevent its eaking. The cow is then let in to her calf, which will greedily take the balance left for him. The cow is again removed as soon as she has supplied the wants of her calf, and so I continue morning and evening, partially to milk the cow before she is permitted to go to her calf, leaving him to do the stripping until he is 3 days old. He is then weaned from the cow entirely and fed with the new milk of the cow by hand, from one of the 'calf's pails,' and so I continue to feed him until he has learned to drink freely, probably at about a week old. I then take away a share of the cream from his milk, and give him a mixture of new and skimmed milk, say two quarts new and one quart skimmed milk, with a spoonful of oil meal or oil-cake ground, sprinkled into his milk, instead of boiled flaxseed. The oil is worth more for painting than for feeding cattle. I therefore let the painter or druggist have the oil and the calf takes the cake. The quantity of new milk is now daily decreased and the quantity of skimmed milk and oil meal is daily increased, until at the expiration of another week, when his allowance becomes 3 to 4 quarts of skimmed milk and a half pint of oil meal, which will make him look as slick as a mole. The milk is warmed a little and the oil meal sprinkled in, and the whole poured into a 'calf's trough' made for the purpose, which is a stick 3 feet long, 12 or 15 inches in diameter, split open, dug out and legs set in of the right length to bring the trough up to his chin, so that he may take his allowance standing in an erect and natural posture. I usually feed two in one trough and see that they are well matched as to performance at least."

My calf's pails are old tin pails whose bottoms have failed, which I supply with a piece of thin soft board cut round, crowded in, and fastened with 5 or 6 small tacks.

If the above suggestions are worthy a place in your valuable paper, you are at liberty to insert them. E.

The subjoined is a very sensible article and worthy of all consideration.—*Ed.*

From the New Genesee Farmer.

On Noxious Weeds.

When rank and a vicious weed usurp the soil,
They cheat the husbandman of half his toil.

During an excursion of some sixty or seventy miles last summer through a part of this county and as far as the eastern extremity of the county of Wayne, I was very much struck with the surprising inroads which foul weeds, of almost every species, are making in this new country of ours. It ought to be a startling fact to the farming community in general, that here in Western New York, where the track of the savage is scarcely obliterated, the Canada thistle, red root, white daisy, John's wort, yellow dock, mullein, and other kinds of noxious plants are, on some farms, almost entirely usurping the place which ought to be occupied by useful productions. Although my own immediate neighborhood is not so much infested, yet I plead guilty to some degree of negligence in this particular; and as my own mind, during this excursion, became thoroughly impressed with the magnitude of the evil, I wish to arouse the attention of others to the ruinous consequences of further neglect.

It is a subject which intimately concerns all land owners. Land infested with these weeds will most rapidly depreciate in value. It is evident that when a meadow or grain field is overrun with any of these plants, it not only requires a great sacrifice of labor to eradicate them, but in most cases, if you go into any thorough and effectual process, you must entirely de-

* The above mode, by continuing the new milk and adding the oil meal, will make a fine piece of veal. I have once adopted it, and it succeeded admirably.

range your farming plans, and probably for a season or so lose the use of the soil.

I have heard it estimated that the clearing of the original forest and preparation of the land for wheat cost only from \$10 to \$12 per acre. At how much less expense can a field be cleared of Canada thistles, red root, or white daisy, when thoroughly besprinkled with them? Carefully estimated, the whole loss and expense, I am bold to say, will not fall far short of that when you see the last feeble stalk expire.

Let these considerations stir us up—and I would especially remind those who, from the newness of their farms or the care of former owners, have escaped this evil, that "an ounce of prevention is worth a pound of cure." If you chance to perceive, in passing to and fro through your field, a single specimen of the above named weeds, don't stop to view it as a curiosity, but attack it as you would a bear; tear it up root and branch—go back to the spot again and see that you have caused complete extermination, so that not a living vestige remains. Let me urge those who, by their own or the negligence of former owners, have pretty thrifty patches of some of these plants, not to delay even if it takes a little time and present labor. Your labor will be exceedingly well spent in seasonally arresting the progress of the evil. As our farms grow older we must expect some drawbacks, and one of these must consist in keeping them clean of foul weeds. The produce of our lands will never come to us in abundance, without pains—we cannot always expect to get along as when

"The earth is young, and yields kindly
—her fruits with little labor."

But I have spun out these remarks beyond what I intended. I will close by observing that it will be of but transient use for a few isolated farmers to attend to this subject. Unless the general attention of land proprietors is awakened, little can be permanently done, where land so frequently changes owners.

There is now an act on our State Book making it lawful for the freeholders of any town in the state, to raise money to defray the expense of destroying the Canada thistle. I wish this enactment might extend to other noxious weeds, and be put into practical operation in the respective towns.

In the counties of Albany, Clinton, and some others, special petition was made to the Legislature, in answer to which a law was passed providing for the destruction of all noxious weeds at the exclusive expense of the owner on whose land they are found. How far this is put in force I will not pretend to say, but if we were all subject to such an enactment, it would undoubtedly be for our ultimate interest.

I. B. SMITH.

Ogden, May 25th, 1842

Fatal Effects of Garget upon a Horse.

MR. EDITOR—I do not think it sufficiently known that Garget is death to a horse. A neighbor of mine was in the habit of giving his horse small ears of corn as he passed his stall. Passing evening before last with some pieces of Garget in his hand, and not having any corn, he offered the horse a piece of the Garget, which it took, and died within twenty-four hours.

Cornish, May 20, 1842.

W. W.

PUNCTUALITY.—If you desire to enjoy life, avoid unpunctual people. They inspire business and poison pleasure. Make it your own rule not only to be punctual, but a little before hand. Such a habit secures a composure which is essential to happiness. For want of it many people live in a constant fever and put all about them in a fever too."

SOVEREIGN REMEDIES.—For the gout, toast and water; hoopoping cough, ipecacuanha; bile, exercise; corns, ear shoes; blue devils, employment; rheumatism, new dannel and patience; toothache, extraction; debt, retrenchment; love, matrimony."

ROCHESTER, JULY, 1842.

Important Notice.

There is a large amount due us from Post Masters and Agents in the Western States and elsewhere, mostly in small sums; it is true, but our whole resources depend on such small sums, and therefore we hope no one will delay sending on that account.

¶ *One word to our friends.*—We have a large supply of back numbers of the current volume on hand, which ought to be in the hands of subscribers. Will you not help us—would you not be doing your neighbors as well as ourselves a real kindness, by soliciting them to subscribe? The currency is now considerably improved, and bills of most of the states will answer for remittances.

PUBLISHERS.

To Correspondents.

The article on E. Foot's valuable and highly improved Tight Air Stove, came too late for notice this month. The article on Onondaga Salt is necessarily postponed until our next number. The communication of M. R. P. on the bee-moth, shall receive due attention. The inquiry of R. respecting the destination of Farmers' Sons, is one of the most important that can be made, and shall have the attention which it deserves. We have to acknowledge a valuable communication from G. S. on the subject of Canada Thistles, which we very unwillingly defer, because received too late. Our respected friend S. W. will we trust, have patience with us for this month. We forwarded at once by his request the papers to New-York.

The NORTHERN LIGHT we receive very rarely; but we know the admirable talent with which it is conducted, and cordially recommend it to our friends as one of the most useful and best monthly journals in this country.

J. V. K. of Little Britain, is advised to cut off the black excrescences or diseased limbs of his plum trees as fast as they appear and immediately burn them. If the condition of the tree is such that he cannot hope for a cure, he cannot remove and burn the diseased parts too soon. His communication on Mildew on Gooseberries we shall avail ourselves of hereafter.

An article on the culture of asparagus in reply to a correspondent, is necessarily postponed.

We thank our friend T. T. from Le Roy, for his valuable communication.

We appreciate the good will of an "Old Dutchman," but should prefer to receive him in his native costume. As it is, he is "out-herods Herod."

Our friend the Vicar of B. V., remembers us kindly. God bless him! We shall not overlook his reasonable inquiries. Heaven send him a Cardinal's robe and cap, if he desires them, or any thing else good which he can ask for short of a heavenly crown. May that coronation be long postponed. Is he the only friend we have left there?

To other friends and correspondents we send all kindly salutations. Though not named they are not forgotten; and though some of their favors seem long deferred, they are none of them overlooked or neglected. If our omnibus continues full, we must presently set up an extra.

We have to acknowledge this 25th June, a small basket of the Methven Strawberry from Mr. N. Dreper of this city. They are extraordinary. We have heard often of two bites to a cherry—here are three to a strawberry.

We thank some friend for copies of a Letter to Lord Ashburton on the Corn and Flour Trade with England. Its views are highly important and must command attention.

We had been promised for this number by competent hands, a notice of Dr. Dana's valuable book, the Muck Manual, and of Alonzo Gray's book on Scientific and Practical Agriculture, but are very sorry to be disappointed. We hope for them for our next number, but alas! for promises for the enforcement of which there is no legal remedy.

We commend to persons interested, the advertisement of John L. Whiting, Land Agent of Michigan. We have no doubt that business committed to his charge will be conducted with the strictest fidelity.

Patronage and Postage.

A subscriber, who informs us that he joined with a neighbor in taking our "valuable paper," price 50 cents per year, informs us likewise, that he is so well satisfied with the publication that he has concluded to take it separately; and, instead of sending by the post-master, takes us 12½ cents for the information. We are certainly obliged by his good will; but it is obvious how soon we should be enriched by such patronage.

Postmasters are authorized to transmit the payment of subscriptions to periodicals, free of charge to the publishers, and are generally kind enough to do it. Here we trust, we shall be excused for expressing our regret for the discouragement thrown by the Post Master General in the way of post masters acting as agents. We deem it extremely impolitic and hardly just. Take our own case. Publishing at as low a price as we do, we cannot afford to employ or send out special agents. Post masters have heretofore always been allowed to act as agents for us, and we cannot conceive in what way it can interfere with their duties. Now our humble sheet, with the postages incidental to it, contributes annually to the Post Office revenue a sum hardly less than three thousand dollars per year. Is it not, therefore, right and just, for the interest of the Department itself, that we should be indulged in this matter. We hope that the other publishers of periodicals in the country, will see how much it concerns them to make suitable representations to the government on this subject.

Notice of Convention of Ploughmakers.

We regret to learn that the notice in our last of a Convention of Ploughmakers to be held at Canandaigua, was regarded as designed or adapted to prejudice a case to be brought to trial before the Circuit Court of the United States, at its June term in Ontario county. No such design was entertained; nor, do we think, that the terms of the article warrant the inference. The notice was inserted at the request of the ploughmakers, who called the meeting and handed by them to the printer. We understand it as expressing their view of the case, and their statement of what they confidently expected to prove. What could be proved, or what were the actual facts in the case, might be an entirely different matter; and of the evidence in the case we know nothing. Had a communication of the facts expected to be established on the other side been presented, we should as cheerfully have published it. In this case we had not even an opinion; and did actually reject a communication in reference to this matter where the facts expected to be proved were absolutely and without qualification asserted. One of the last things we should be willing to do, would be to interfere in any way whatever, to disturb the impartial administration of justice between man and man. Allow us, as it seems to be necessary, to add to what we have before said, that we hold ourselves in no respect responsible for the opinions and notions either of our correspondents or advertisers,

unless we directly and explicitly endorse them. As his subject is a matter in which the farmers are much interested, we shall report the decision of the Court soon as received. Our only desire is that the right may prevail; and this is always ultimately for the good of all.

Since the above was in type, we are informed that the decision of the Court has been given against the claims of the heirs of Jehro Wood. Of the particulars of the decision we are not apprised.

June 27th.

New Agricultural Store.—Farming Implementments.

We are much gratified to learn that B. F. Smith & Co. have opened a store in Syracuse, N. Y., for the supply of the best agricultural implements of every variety, which the New England or New York manufacturers can furnish. If this establishment is well conducted, there can be no doubt that it will afford eminent advantages to the farmers of Western New York, of which we hope they will fully avail themselves.

We cannot advise farmers to be in a hurry to get every new tool or implement, which presents itself and promises to effect a great saving of labor; for in many cases the promise is delusive; and the saving proves only an increase of labor, and no little expense. We advise them not to purchase too many tools, for the use of them will be troublesome, and the more they are multiplied the less care is likely to be taken of them. We advise farmers not to purchase any implements or machines, which promise to do half a dozen things by the same operation, for in this case they are generally complicated and liable to get out of order, and if out of order, not easily mended or repaired. Besides they seldom do many things well. We advise farmers likewise to remember that the best of all machines is the human hand, when guided by a sound judgment and a clear eye. But then we advise them to obtain all such implements as are necessary for the proper management of their business, and never to live by borrowing, which is generally the means of all ways of getting along, and makes a man a perfect nuisance to his neighborhood. We advise them to get the best tools and to keep them in the best order. We remind them that there may be a great saving in the kind of ploughs which they use, some doing the work far better than others, being handled with much more ease; and requiring perhaps not half the power of draft which some others require. We remind them that a good sowing machine may enable them to sow their grain much more evenly than they could otherwise do it, and with a great saving of seed. We remind them that a cutting machine of the best kind will enable them to save certainly a third of their hay; and their cattle, if well fed in this way, will be in better health and condition than when fed wholly upon long feed. We advise them by all means to have a good roller, a very rare and yet one of the most useful implements on a farm, for sinking the seed, for forcing the stones into the ground where there are stones, so that they may be out of the way of the scythe, for crushing the clods so that the tillage may be made finer and for leaving the land in a clean and handsome condition. We advise, likewise, to a farmer's having a revolving horse-rake wherever his land admits of its use, as saving, when well managed, at least two thirds of the labor. So we might go on with further counsel, but this will do for a beginning. Whatever a farmer gets, let it be of the best quality. We do not mean that his plough should have either gilt or mahogany handles; but we would have it made of the best materials, in the nearest, strongest, and most substantial manner; and if it should be painted and kept well painted, and slightly

OATS.

Will the Editor please state in the next number of the Farmer, the usual quantity of oats sown on an acre by the common farmers in England and Ireland, and also the most suitable quantity for New England on ordinary or highly cultivated land. Any remarks upon the subject which the Editor may have time to make, would be read with interest by a subscriber.

R.

The usual quantity of oats sown on an acre in this country is three bushels. The quantity sown in England is from four to six bushels per acre. The English farmers are in the habit of sowing more seed to an acre than is done with us. Of the potatoe oat, one of their heaviest oats, less seed is used than of others, because it has no awns, and a half bushel measure contains more oats in number than of other kinds. The cultivation of land in England is very much more careful and thorough than with us; this may be a reason for sowing more seed. The quantity of seed to be sown upon an acre of any grain deserves consideration, and especially experiment. One of the best farmers in Massachusetts is accustomed to sow three bushels of rye, and says he finds an advantage in doing it, whereas few farmers sow more than one bushel to the acre. Of spring wheat our farmers sow usually two bushels; of winter wheat one and a half. In sowing wheat in autumn, a difference in the quantity of seed is made by judicious farmers, as that which is sown early has more opportunity to spread, or as it is termed, to tiller well, and consequently less seed is required. Where the land is rich and the cultivation good, we are strongly of an opinion that too little seed is generally sown. Where the grain is thin, the crop is more apt to suffer from drought. Oats require a moist and rather cold climate. We have known more than one hundred bushels upon an acre; and an average crop of 93 bushels to the acre, from a field of eight acres. The general average through the country is not over forty bushels. No attention is paid to the selection of seed with us; but abroad the largest oats are sometimes picked out for sowing. We have no doubt that more care in this respect would be amply compensated. A careful selection of the earliest, fullest, heaviest and brightest plants in the field would presently give a farmer a crop much above ordinary. Of the two kinds cultivated among us, the common branching oat and the Tartarian or horse-mane oat, where the panicles hang all on one side, the latter is thought to yield the heaviest crop. An eminent farmer in New Hampshire, in whose judgment we have great reliance, prefers this kind, and his crops for years have averaged about sixty bushels per acre. Some persons allow the kinds to become mixed, but they do not ripen at the same time; and the common oat gets into a condition to waste or shell out before the Tartarian becomes ready for harvest. Oats should be cut early; they are less liable to waste, and the straw is deemed better for the stock.

On Making Butter.

MR. COLMAN—I am no farmer, but have, on looking over your paper, noticed a communication from Mr. Bennett in the April number, upon the subject of making butter in winter, together with your remarks, and was much pleased with the importance which he and you attached to it. Butter is truly an important article, and there is nothing that comes upon the table about which people are more squeamish; hence the best methods of making it at all seasons of the year are worthy of consideration. It is generally conceded that there is very little difficulty in making butter during the season of grass—the quality depending upon the skill and neatness of the maker; but how to make good sweet butter in winter, that is the question. Much de-

pen is upon the cow, the manner of keeping and feeding, but much more upon the management of the milk. The experiments of Mr. Bennett are valuable, but I am quite certain from my own experience, or rather from the experience of my wife, which is the same thing, that equally good results may be attained at a much cheaper rate; by dispensing with the expense and inconvenience of double pans, and the trouble of scaling the milk, and substituting a more simple process. After trying various experiments, she has settled down upon the following simple plan.

In the first place, the greatest care is taken to have the milk things clean and sweet; the milk is strained into common tin pans immediately after coming from the cow, and set in a room warmed by a stove. It stands usually 30 hours, when it is skimmed, and the cream, with considerable of the milk, put into a stone crock in the same room. In 3 or 4 days enough is gathered for a churning; if it is not sour, the crock is set into a tub of warm water until it is sour. It is then put into the churn and converted into butter, usually in from 15 to 25 minutes. Following this method, our table has been supplied during all the past winter with butter so fine that it has been much admired, and pronounced equal to June butter, excepting only the color, which is not so deep a yellow; we have never used carrots either for coloring or feeding. There is no danger of a failure in churning; never, since this course has been pursued, has there been a single churning put by because it would not come. There has been no witch in the churn, and consequently no need of putting in the heated horse shoe to drive her away, as I have known done at. I have never ascertained the exact quantity of butter made from a given quantity of milk, but having but one cow, have been very particular in weighing from week to week for three months. From the middle of November, (a few days before which time the cow calved,) we found an average of ten pounds per week. The cow is a half Durham, 10 years old, from a bull which was brought into this village some 12 years ago from the vicinity of Boston, said to belong to the family of the stock presented to Massachusetts by Admiral Coffin. She has been fed during the winter with a mess of wet shorts night and morning, with occasionally some potatoes; frequent salting; good hay, and a warm stable.

We find a decided advantage in skimming, to take up considerable of the milk with the cream, and let it go into the crock, and by frequently stirring it together I think, Mr. Editor, that I can furnish a satisfactory answer to the question put to you by your fair friend, in relation to the trouble which so often happens in churning. We have always had difficulty when the cream was sweet; but since adopting the above plan, no such thing has occurred.

Respectfully yours,

SAML. H. ANDREWS,

Canandaigua, 1842.

Summer Beer.

To make the best flavored, cheapest, and most innocent beverage used, (save water,) have a strong cask painted, to make it impervious to air—commence by putting in (say for 10 gallons water,) 1 quart yeast, 5 pints molasses, a few drops oil of spruce—a quart for the aforementioned, should be of the capacity of fifteen gallons, to be without a bung, and to stand on one head; in the other a hole to put in the ingredients—to be tapped about two inches from the lower head; when all is in, stop it tight, by the cask down and violently agitate the mixture for a minute, then open the cock and a quantity of air will rush in, when it stops, shut the cock, and rock another short spell, open and air will again go in, but not so much; so operate as long as air will enter, then stand it up, and in the course of a few hours it will be fit for use. To accelerate action, a will be well the first time to put in a pail of hot wa-

ter. It will keep good but a short time, and will soon be tart; then draw it off, if any is remaining, down to the cock, and put it into a vessel, and in time it will become vinegar. To make again, you have only to put in the water necessary, half a pint of molasses per gallon, and a few drops oil of spruce, and shake as before. Air must not be allowed to escape, for if it should the beer will be good for nothing.

Cornish, May, 1842.

W. W.

We give the above recipe, which has been kindly sent to us, with our plain advice to let it alone. There are few things worse for laboring men than small beer; for we have never known a case, where it was furnished liberally, that men did not, as Cobbett says in his emphatic way, "make swill tuls of their bellies." It is very much so with molasses and water, modified as it often is by a profusion of ginger. Men, when they get their mouths to the mug, never know when to take them away, and it goes down their throats like water in a shower down the spout. Coffee, chocolate, milk and water, or nature's pure moonshine from the crystal spring, is never swallowed with the same insatiate greediness. We believe, likewise, that few things sooner disorder the stomach and impair its tone than this habit of excessive drinking of small beer, molasses and water, &c., especially in hot weather. We know that success in attempting to persuade men to govern their appetites, is well nigh hopeless; but long observation and experience under hard labor has satisfied us, that if possible, it is best never to drink anything excepting at the regular meal times; but that especially it is best never to drink any thing in the forenoon; that water, pure water, is the most safe, nutritious, and invigorating of all liquids which can be taken into the stomach, and when drank in moderation may be used with perfect confidence; and that more than three meals a day is hurtful instead of beneficial. If one is dry, a little piece of cracker chewed will produce a secretion of the saliva and the thirst will be quenched; or if any thing more is needed, let it be a draft of clear water. We advise for laboring people, and we do not speak without some experience on the subject, breakfast from six to seven, dinner at twelve, and tea between five and six. If something more is needed, let it be a bowl of milk in the evening when all work is done. But all ten o'clock's and four o'clock's are pernicious.

We have known an excellent drink prepared on a farm where a hundred acres were annually under the scythe, and other things in proportion. It was thus; from a pint to a quart of fine oat-meal was put in a two gallon jug, filled with water, and well shaken and kept in a cool place. It would very soon be fit for use, and very soon become agreeable, and always prove a good quencher of thirst as well as assafe and nutritious. It is quite unnecessary to say before trying it, that we should not like it. All of us are the creatures of habit and we have few tastes, even among the strongest, which are not acquired, and oftentimes in spite of original aversions and disgusts.

On Retting Hemp.

MY DEAR SIR—In addition to my communication to you on the cultivation of hemp, I feel that I may render a service to the inexperienced cultivator in being more particular as to the proper season for retting. The importance of this has been mentioned to me by a gentleman in the business, on seeing my letter published in the April number of the New Genesee Farmer. This suggestion, with a wish certainly not to mislead the agricultural public, and to answer some inquiries made of me from abroad, has induced me to speak more particularly on the process of retting.

It is important that the retting should be finished in cold weather; if the hemp freezes as soon as drawn from the pond, so much the better. I have seen hemp ponds frozen several inches thick; this is broken up by drawing off the water.

The first of December, in our climate, may be considered a proper time for taking hemp from the water, and the average time required for rotting is about six weeks. A sled drawn with a chain by one yoke of oxen is a convenient way of removing hemp from the pond to the upland to dry. It should be carefully laid on the ground in bundles to drain, and become stiff enough to set up in open bunches against the fence to dry, where it may stand without injury all winter. You will understand that the pond must be an artificial one, that it may be drawn off at pleasure.

Perhaps you may be able to condense something from this that may be useful to some of your subscribers. Yours as ever, J. WILSON.
Dorfield, Mass., 1812.

Comparison of English and American Farmers.

We publish the subjoined letter with much pleasure, and have only to regret that, owing to our absence, it did not appear in its proper place. Its references, however, are perfectly plain and intelligible. We can hardly persuade ourselves that Wm. Howitt's account of an English farm dinner can be intended to give a picture of every day's life. If so, anchorite as we are, we must go for American sobriety, or what perhaps our friend would call abstinence, not to use any harder term. In one particular, however, there must be a great difference. The farmers whom Howitt describes, are what we should call the middling classes, the tenants of the farms or the managers. We have no such class. Our farmers, properly so called, are all laboring men; and we apprehend upon a comparison of the tables of the laboring men in England and Scotland with the tables of our farmers, the comparison would be strongly in favor of the latter. The farmers, whom Howitt describes, would here belong to what we should call gentlemen farmers, men who would as soon think of jumping overboard as jumping into a farmer's flock, and whose whole business is to command and direct the labors of others. In England this class of men, who are after all mere tenants or overseers, keep their hounds, their race horses and hunting horses, and indulge in the luxuries, if so they may be called, incident to such establishments, as much, though not as expensively, as the highest gentry in the kingdom. We have no such class among ourselves; and whether the general morals and general comfort would be increased by their introduction, it will be time enough to say, when it is likely to take place. At present we think there is little probability of it.

DEAR SIR—I consider the letter of S. W. in your March number, so replete with errors, that I cannot let it pass unnoticed. I should have answered it in your last number, but I expected that Mr. Garbutt, to whose letter it was a reply, would have noticed it; for surely he cannot find any difficulty in sustaining the position which he advanced, on the superiority of the English climate for the general purposes of agriculture. Now in the first place, I cannot agree with S. W. that if Indian corn could be raised in England, it would better the condition of her "starving population." For I have observed in this country that when the season has been favorable for corn, most other kinds of grain and root crops, and also pastures and meadows, have suffered. Granting corn to be a valuable crop, still it is not so valuable a crop that the farmer would wish to sacrifice all others for the sake of raising it. It is a well known fact, that the average of all kinds of grain grown in England is higher than here, and the quality of some, as oats and barley, is very superior: this I think may be fairly attributed to the climate, unless S. W. chooses to ascribe it to the superior industry of the English farmer over the "ease-loving farmers" of this country. Then there is the horse bean, which cannot be grown here, which I consider equal to corn for all feeding purposes; it is grown to a great extent in Eng-

land is cultivated and harvested at less expense than corn, and is an excellent preparatory crop for wheat. Then look at the great extent of the root crops, and the immense advantage of the English climate in not making it necessary to protect the turnips through winter. How is it possible, with our winters, to grow root crops extensively, when all have to be put safely away in cellars or pits?

One word to our friend M. B. B., who has given us an account of Mr. Sheffer's root crops to show that roots can be grown extensively in this country. Now I understood Mr. Garbutt in using the word "extensively," as applying it to the growth of roots in England. Mr. Sheffer has certainly done well, and deserves great credit, but should an English farmer, or any friend for him, boast of raising 6500 bushels of roots, he would assuredly get laughed at. But above all, look at the verdure of an English pasture, which gives a richness to the face of the country, the absence of which here gives to an Englishman, on first travelling through this country, an idea of barrenness and sterility. Wm. Howitt, in his work entitled "Rural Life of England" says "one of the great charms of the country, dependent on its climate, is that rich and almost perpetual greenness, of which strangers always speak with admiration."

S. W. asks what would become of our "ease-loving farmers if they had to encounter the cold, sour, wet climate, &c., of England? would they not be reduced from bacon and corn bread, to turnips and pea soup—from the delicious wheaten loaf and hot rolls, to oat cakes and potato broth?" I cannot possibly tell what would become of our farmers, but I can tell how the English farmers fare under what S. W. considers such adverse circumstances. And I cannot do better than quote again from Wm. Howitt. After describing a substantial luncheon, he comes to the dinner. "The hour arrives; well here they all are; and here are the ladies all in full dress. Hands that have been handling prime stock, or rooting in the earth, or thrust into hayricks and corn heaps, are washed, and down they sit to such a dinner as might satisfy a crew of shipwrecked men. There are seldom any of your *richesy wretched soups*, except it be very cold weather, and seldom more than two courses; but then they are courses! all of the meat kind seemingly on the table at once. Off go the covers, and what a perplexing, but unconsumable variety. Such pieces of roast beef, veal and lamb; such hams, and turkeys and geese; such game, and pies of pigeons or other things equally good, with vegetables of all kinds in season, peas, potatoes, cauliflowers, kidney beans, lettuce and whatever the season can produce. The most potent of ale and porter, the most crystalline and cool water, are freely supplied, and wine for those that will; when those things have had ample respect paid to them, they vanish, and the table is covered with plum puddings and fruit tarts, cheese-cakes, syllabubs, and all the knickknackery of whipt creams and jellies that female invention can produce, and then a dessert of equal profusion."

But really, Mr. Editor, I will not tantalize you and myself by enumerating all the good things, but if you have not read the work from which I have quoted so largely, do read it. The author then goes through tea, and finishes up with a substantial supper of hot game, fowls, &c. He then concludes the chapter by remarking, "such is a specimen of the festivities of what may be called the middle and substantial class of farmers; and the same thing holds, in degree, to the very lowest grade of them."

If this be a true picture, which I know it to be, you must agree with me that S. W. has paid a very poor compliment to the industry and intelligence of our American farmers, to suppose that with a climate similar to England, they would be reduced to live on turnips and pea soup, oat cakes and potato broth. B. M.

Book-Farming.

MR. EDITOR—I have been an attentive reader of several agricultural papers for four or five years past, and trust I have been well paid in the knowledge gained; at any rate I have received from them much gratification. I think one great benefit to be derived from their perusal, is the exciting a spirit of enquiry.

I have been termed among my neighbors an experimental "Book Farmer." I have failed in many things, and succeeded in others, but in the most important of all, that is in making money, I have met with a total failure. I propose, therefore, to give to my brother farmers my practice and experience in full, and my opinions rather generally, on a variety of subjects, although somewhat disconnected, and yet such as I believe have an important bearing on the true interest of the farmer. If you deem them worthy of insertion in your valuable paper, I shall feel much gratified in having furnished them. My motto is, that every disease has a remedy; but we must first point out the disease, before we shall be likely to discover the remedy.

Would not agricultural papers benefit the farmers still more, if they would examine more fully the Statistics of the Country; and instead of urging us on to over-production in some things, tell us how we may raise enough (and no more than enough) to supply the market, and at the same time get the greatest returns for our labor. In my opinion, much more money would have been made by the farmers, if they had been timely informed of the amount of Pork in market kept over from last year, and how much would be required this year to supply the demand, being myself convinced that if there had not been more than one half of the surplus produced this year, that the farmers would now have had more corn in the crib, and the one half would have put more money in their pockets, than the whole amount of the proceeds of their pork has done. Such are my views of the effect that supply and demand has in establishing prices. On this branch of the subject and some others which I wish to discuss hereafter, there is a broad field left wholly uncultivated, that needs deep ploughing with a "strong team." I shall attempt only to clear off some of the underbrush, and leave the use of the subseil plough to some one who drives a "stronger team," as I am admonished that my stumbling ponies will not be able to do the work effectually.

The manufacturing, commercial and mercantile interests, have for a long time supported papers devoted exclusively to their interests. They have read and collected the statistics of the country and they better understand the law of supply and demand, and ability to pay, than the farmers. What would the manufacturers think, if the papers devoted to their interests were to stimulate them to produce or manufacture twice as much as was required for consumption, when the same article could not be exported except at a loss of 50 or 100 per cent, on the first cost?

I wish to cast no censure—my only object is to awaken a spirit of inquiry. The farmers in this country never have been awake to their interests. They have been content to let others do their thinking for them, and as long as they continue on in that course, they may expect the certain consequence—that,

"In every hand, and on every soil,
Those who think, will govern those who toil."

And if we surrender those inestimable privileges to others, on the account of our stupidity, how can we expect that our interests will be properly attended to?

We ought to pursue, in my judgment, a more definite system in all our operations. We ought to know the precise and relative cost of all our productions—in every state, on every degree of latitude and longitude, and according to the several specified modes of cultivation as practised by a majority of the American farmers. With such data before us, we should be able to under-

etand adapt our production to the soil and climate, and turn our attention to the cultivation of that which was most profitable, and consequently keep up a more steady equilibrium of prices. As it is, I am satisfied that some few of our products yield us a fair compensation for our labor; and that there are others which might do so, which we do not now cultivate; but there are many more that do not yield us one half of the expense of cultivation at present prices, counting labor worth but fifty cents per diem. It is a mistake to suppose that one mode of cultivation or kind of production, will answer equally well for every section of our diversified soil and climate. What is profitable in one section is unprofitable in another.

I fully agree in every particular with your valuable correspondent, W. Garbutt, in what he has said, in his comparison of English and American agriculture; and I would apply the same reasoning to the different sections of our own country. It may be profitable or good economy to cultivate roots on a large scale for feeding stock in the vicinity of our cities and large towns, where laborers are more plenty, land dear, and hay worth from ten to twenty dollars per ton; but from my own practice and experience, I am convinced that it has cost me on my farm from fifty to one hundred per cent more to winter a creature on roots, than it has on hay.

Permit me here to remark, (with a desire, not to appear censorious, as it certainly is contrary to my feelings,) that the agricultural papers, in recommending a system of cultivation, have not duly considered the natural differences of soil, climate, prices of labor, products, lands, &c.; but have too generally recommended the same system for every section of country. Or perhaps, they have supposed that the farmers themselves would take those things into consideration; but the farmers omitted to use their natural faculties, and consequently have failed in their first experiments, which is the cause of some of our best farmers entertaining strong prejudices against what they sneeringly term "Book Farmers."

I was much pleased with the manner which you treated the subject of a threatened withdrawal of patronage, because you admitted an article in your paper that did not correspond with the views of some of your subscribers, on the subject of Protective Duties. You say, and say truly, that it is a matter of great national importance, and a question that concerns the farmers as much or more than any other class; and further, that you are willing to hear, and let your readers hear what may be said on both sides of that great question. I have read several times, and with great satisfaction, the article in your January number complained of. I consider it a spirited, well written article, and an honor to the head and heart of the writer—a containing the sentiment of a true American, and I perfectly free from the "advocacy of British interests." I ask your respected friends, if they have not seen much stronger articles in the Farmer in favor of protective duties than on the opposite side of the question, or the one signed S. W., the article objected to. Suppose that S. W. or myself should threaten to withdraw our patronage on that account, what would you think of us? would you not say that our cause was a bad one, if it would not bear discussion and investigation, or

"He that will not reason is a bigot,
He that dare not is a slave."

But, Mr. Editor, you need not fear that S. W. will withdraw his patronage of 50 cents or 50 dollars, because a portion of your correspondents differ with him on that subject. I will vouch for him, although an entire stranger to me; yet I am certain he does not fear free discussion.

Should you consider my desultory remarks worthy of a place in the Farmer, I propose giving at some future time, an estimate in detail of the first cost of pro-

ducing the several agricultural products of Michigan, found on an assumed basis, of improved land at \$20 per acre, labor at 50 cents per day (by the year), and 6 percent interest on the capital invested, which is not very far from the real standard. And trust that some one, if not all, of your correspondents, in the different sections of this glorious country, will concur with my views on this subject, and make it manifest by sending in their estimates in detail, with all the circumstances, whys and wherefores, for publication.

J. S. DUTTON.

Monroe, Michigan, 1842.

Reply to Zelia.—Defence of Farmer's Wives and Daughters.

MR. EDITOR—I would not intrude upon your patience so soon again, if I did not feel a little excited about some of Zelia's remarks, which, though good and full of interest, I consider as not applicable to farmers, their wives and their daughters generally. I commend the discretion and wisdom she is anxious to enforce, but would guard against views which I conceive to be erroneous.

In the first place, she calls upon women to consider whether their influence goes to promote temperance, industry and their natural results, or the opposite. These considerations deserve the attention of every mother and daughter, every father and son. The mind and the body are so connected, that the occupation and condition of the one sensibly affects the other. When we labor with our hands, our minds almost unconsciously imbibe sentiments and feeling which the employment is adapted to inspire. When we open our hearts to the influence of piety and compassion, our hands are prompted to acts which may alleviate the sorrow and distress our eyes behold. For this reason, it is judicious and highly desirable for all persons to employ their minds and thoughts in a manner that may actuate their hands to perform their duty; and study to use physical strength in a manner that may impart to the mind the satisfaction resulting from a useful and virtuous life.

She further adds, "that she believes it is generally admitted, that the extravagance that characterizes our age, the enormous expenditure of time and money on mere trinkets, is the predominant cause of the embarrassments of our times. I suppose that politicians would differ on this point. Be that as it may, I really do not believe that the trinkets of the farmers, their wives or daughters, would amount to a vast sum. They generally understand too well that their money is hardy earned, and therefore prize it too highly to trifle it away. I should have supposed that Zelia intended her remarks for a certain class, to which it would be very applicable, if she had not said "no particular class is exempt from the charge." Now I contend that farmers, as a general thing, are exempt from extravagance in any thing, except the idea that they are too poor to lay out a great many dollars in enlarging, cultivating and ornamenting the minds or persons of their children, or of affording themselves the means of useful instruction. Not that I would advise or wish any one to live beyond their means; not so, but every one should study to make themselves useful, and use the means which God has given them to elevate and improve, to refine and polish, the mental powers and personal qualities, for which the means of improvement have been so amply provided. I should be sorry to indulge any unjust prejudice, but the farmers are more exempt from this reproach of extravagance than the working classes of the cities and villages, as they live more secluded from the fashionable and vain, and consequently have less to tempt their love of show and splendor.

Again she says, "all have lived beyond their means, beyond the limits of common sense and pru-

dence," &c. I must think if Zelia were as well acquainted with the habits and management of farmers as I am, she would not have said all. That they have been to a degree involved in the general ruin and distress that pervades the country, I do not deny. But that it has been brought upon them through the mismanagement and extravagance of their wives and daughters, or even their own, I cannot admit. That the merchants and mechanics, the professional men, and the drones, have long indulged in a vain and deceitful ostentation and extravagance, is evident. But the farmers, although their produce has been much of the time almost unmarketable, and when sold, sold at reduced prices, and on credit, still by the persevering industry of themselves, their wives and their daughters, and the economical management of their business affairs, they have braved the storm of broken banks and broken credit, broken fortunes and broken spirits; and by a uniform course of good policy and praiseworthy self-denial of the dainties and luxuries of life, they have saved their own and many other fortunes. How seldom do we hear of a farmers breaking or losing his farm, except through the generous endeavor to save an unfortunate friend or falling neighbor, or by some rash trade or speculation, wholly foreign from his proper pursuit as a farmer.

Again she says, "no person or people who consume more than they produce, can long escape being enslaved some way or other." As Zelia has made no exceptions before, I conclude she did not intend any here. There may be some it is true, among the farmers, that are possessed of a false and vain ambition; but I fancy they are few, compared with those who deem time and money expended in the cultivation of the mind and person, as almost wasted and improperly applied. It must be evident, that this paragraph cannot touch the farmers, who support the whole combined mass of all classes; the high and the low, the great and the small. If instead of confounding the industrious and frugal wives and daughters of the land with the city automaton and village dolls, who view labor as degrading, and those who labor as slaves, if Zelia had made a wise distinction, and directed her remarks to those whose views are bound up in purposes of ambition, or their lives consumed in a round of idle indulgences of fashionable dissipation, and who subsist only on the plunder of the fruits of the industry of other men, instead of implenting the industrious and independent yeomanry, then I would heartily have concurred in her views. But Zelia, this will never answer—we have come within an inch of politics—and shall be very likely to get a lecture, or an excommunication, either of which would be—dreadful.

But to atone, Zelia, for the liberties I have taken, let me say, had you and I lived in ancient times, and I had happened to have been a priestess at the temple of Delphos, I would have consecrated in golden letters (with the precepts there) your remarks. "I am not desirous of curtailing the pleasures of life, or hoarding up riches for their own sake; but would recommend such economy as will promote permanent and rational happiness; and enable us to do good where the opportunity presents itself. For any other purpose the acquisition of wealth is scarcely worth a thought."

Let this ever be our motto; to combine in a consistent and reasonable manner, the useful with the refined and the ornamental. FLORA.

Ploughing in Vegetable Crops to Enrich the Land.

We publish to day a communication of "Turnipseed" (pray take some other name) on the subject of "Growing Wheat on Inverted Greenwards;" to this we are glad to add a communication of Mr. Tufts of Le Roy, on the subject of destroying Canada Thie-

ties, and his brother's experiment of raising wheat on the same ground. To this we shall hereafter add the experiment of Mr. Kelly in Haverhill, Mass., on raising a crop of rye after ploughing in a crop of charcoal. This account was given to the public in the Transactions of the Essex Agricultural Society, and afterwards in Colman's First Report of the Agriculture of Massachusetts. It will be found of the highest importance. The whole of these communications bear upon the same point, the great value of vegetable matter turned under for the nurture of the ensuing crop.

We shall take occasion here to relate a case of our own, from which we ourselves, had no other person, derived some instruction. We had in our employ at the time two Englishmen, bred framers from their childhood, and skilled and competent in every branch of husbandry. We gave them an acre of land, a clover ley, and desired them to prepare for and cultivate it in turnips after their own fashion, engaging on our part to offer in no way either advice, interruption, or interference. A crop of clover had been taken off early, and they then proceeded to plough and harrow the land thoroughly, and then to pick out every root and every particle of grass left, putting it into small piles, and burning it on the ground, giving the land as they termed it a thorough *cleaning*. The land was highly manured afterwards, and the crop of turnips was good and cultivated in drills in a very fine style; but we had no doubt at the time and have so little now, that it was a great error to rob the ground of all this vegetable refuse; that the crop was less than it would have been but for this abstraction; and the fertility of the land reduced for a length of time. The land was afterwards laid down to grass, and we were satisfied suffered much from this *thorough cleaning*.

On Growing Wheat on Inverted Sward.

MR. COLMAN—Allow me to call your attention to an article in the January number of your paper for this year, on page six, entitled "Three Experiments in Wheat Growing," and signed by "Agricola," dated Greece, Monroe county, N. Y.

I am myself, like Agricola's, a young farmer, and have likewise been a merchant, and have also a friend to advise me respecting my farming operations, to whom I showed the above article in your paper this morning, at the same time asking his advice about practicing upon the above experiments of Agricola.

He objected entirely to the manner and method of the second experiment, but finally said that it might possibly do to treat a clover lot after that manner, that is, (i. e. the clover) would be killed, and what wheat there was would be clean, but did not believe it would produce a good crop—that the seed could not be well covered and would be liable to freeze out—that the ground would be hard beneath the surface, and the grain would not be well rooted. He did not believe the third method would answer at all, as the natural grasses would never be killed, and would grow up in the spring and destroy what wheat did grow, which he believed would be but little.

He said that there were a great many things written for agricultural papers which would not bear examination, and be believed that this was one of them. That many theories were advanced rashly without being sufficiently experimented upon, and that he did not believe that either the second or third method was as good as the first, viz: old fashioned summer fallowing.

On page eight of same paper, in an editorial to readers and correspondents, "Agricola" is welcomed to your columns and a desire expressed to hear often from him.

I presume that desire would not have been expressed, if the editor did not think well of his communi-

cation and believed what "Agricola" said was substantially true, and that the experiments had been actually made.

The object of this communication is to ask if Mr. Colman has any personal knowledge of his correspondent, or whether if in Mr. Colman's knowledge the practice of summer fallowing has given way to "Agricola's" system, in any of the numerous farming districts which he has visited, and with what success. Perhaps this communication, if published, may draw out "Agricola" once more, but I hope not angrily at the doubt thrown out about the results of his practice and experiments.

Respectfully your ob'tserv'r,

TURNIPISEED.
New Windsor, Orange Co., N. Y.

Editorial remarks on the above.

In reply to the inquiries of "Turnipseed" we have only to say that the authority of Agricola for the three experiments in wheat growing, deserves his entire confidence. We have known the system practiced upon by two of the best farmers in the whole country, Earl Stimpson of Galway, Saratoga county, N. Y., and Eliza Phinney of Lexington, Mass. We have known, likewise, other cases, where the same husbandry has been pursued. Success, however, must essentially depend upon the manner in which the ploughing is executed; the sward should be so neatly and completely inverted that all the growing vegetable matter may be covered. The decay of this vegetable matter will furnish nutriment for the growing plant.

Another point, which is not generally understood, but is so well settled by the experience of judicious farmers, given without concert with each other, and without knowledge of the opinions of each other, that it may be considered as ascertained, is that it is much better to plough in this vegetable matter after it has become perfectly ripe, decayed or dead, than in a green or succulent state. For spring grain there would of course be no difficulty in doing this: to wait for this in autumn might carry the sowing on too late in the season. We shall not enter into the philosophy of this, though good reasons may be given; the fact is all about which in the present case we are concerned; and that we deem established.

As to the objections of the sceptical friend of Turnipseed they do not surprise us. We admit that a great many things are written for and suggested in agricultural papers, which are not well established and which must rest upon the responsibility of those who offer them. Where they are clearly erroneous and would be likely to lead our friends into mistakes, we certainly should accompany them with a caution. Where we know them to be well founded and important, we should, if we deemed it necessary, endorse them. Where they are doubtful or altogether speculative, they must pass with our readers for just what they deem them worth: but they are surely not to be considered as our views because we insert them, nor in any case, unless we openly and directly approve them. An agricultural journal must be open to free discussion on all subjects connected with husbandry; and though we have a tolerable measure of confidence in our own judgment, we claim no infallibility, and will not reject statements or opinions of respectable correspondents because they may not quadrate with our own.

As to the other objections of his sceptical friend, which spring out of his superabundant self-confidence, we hardly think they deserve a grave answer. There are a good many men in the world, who have never yet found out that the earth turns round and it is quite probable they never will. Let such men calculate their own almanacs, and let us be thankful that the

cause of an improved or an improving agriculture, or any other cause of public or private improvement, is not left in their hands. Put such men into a canal boat under full way, and you could not make them acknowledge that the boat moved; no, it is only the land running away from them, they *know* it because they see it.

Army Worm and Cut Worm.

(Extract of a letter dated *Manassas City, June 21.*)

The army worm is making dreadful ravages in this county and in some other parts of the state, taking whole pieces of wheat and mowing grass nearly clean as they go—or at least so much as to ruin the crop. This cut worm has also done very much damage this spring, cutting off almost entire fields of corn. I saved mine by one of the three following operations, or by them all combined. First, by ploughing my bottom lands very early in the spring, say first of March; secondly, ploughing lightly and dragging thoroughly just before planting; and thirdly, I soaked my seed in sulphur water 24 hours before planting. What think you?

I was less fortunate in my garden: the cut worm took almost every thing, and finally I set out a large patch of cabbages and they took them clean. After a good rain I set out more, using as many of the common preventives as I could bear, but all to no purpose; and the second day they had ruined about 200 plants. About 5 o'clock of that day I received your excellent paper at the office, and by the time I reached home I found a remedy recommended; I immediately set about it, and put about a table spoonful (of salt) around the stalk of every remaining plant, and in the morning, to my astonishment, not another plant had been touched, neither has one been injured since. So much for being a subscriber to the New Genesee Farmer. When will all my brother farmers learn wisdom at so cheap a rate.

J. W. SMITH.

We give the above from a valued correspondent, not presuming to endorse it with much confidence, after the trial of a single night. A table spoonful of salt, applied directly to a plant in this way, is quite as likely to kill the plant as the worm. About as much as is recommended to be applied to a pigeon's tail in attempting to catch them, would certainly be much safer. Salt intermixed with the manure or laid near, but not in contact with the plants, may have the desired effect, but on this subject let us have experiments.—*Ed.*

*They only eat herds grass—they do not touch clover

Non-Resident Lands in Michigan.

THE undersigned respectfully announces to the public, that he has opened an Office in this city for the specific object of acting as a general Agent for the payment of Taxes on non-resident Lands, now, or hereafter, to become due, in any of the Counties of this State and he will visit himself, or by a proxy person, each of the Counties, to obtain all necessary information upon the subject, and to see that the persons wishing taxes paid in any of the Counties in Michigan, and forwarding to the undersigned the necessary amount of funds a fee of postage, together with an accurate description of their lands, may rest assured that their interests shall be scrupulously attended to.

His charges with all taxes be reasonable, and proportioned to the services rendered. The undersigned will endeavor to make himself thoroughly acquainted with the value of Lands in every part of the State that he may be enabled to give information to all enquirers in this respect, will undertake the sale of the same. He begs leave most respectfully to refer as to character, and capacity, to redeem the pledges above given, to the annexed certificates.

J. L. WHITING.

Detroit, March 4, 1840.

I think such an office as is proposed by Dr. J. L. Whiting is highly necessary for the convenience of the community, and that he is exceedingly well qualified by long residence in Michigan, his knowledge of the country, strict integrity, a correct business habits, &c. the duties of the proposed Agency.

Pres't of Michigan.
I concur fully in the sentiments and opinions expressed in the above note of Mr. J. L. Whiting. Detroit March 5, 1840.
WM. A. O'BRIEN, Governor of Michigan.
I have been acquainted with Dr. J. L. Whiting for many years, and fully concur in the views above expressed by Mr. Townbridge.
E. FARNSWORTH, Chancellor.

Sayings and Doings, No. 1.—Wintering Sheep.

MR. EDITOR—It was a saying, it is said, of the notorious Sam Patch, "that some things could be done as well as others." This last fatal leap from the falls of your beautiful city, tells us that the maxim is true in part only. He had already, by his famous leaps, sufficiently immortalized himself. They were considered hazardous experiments—being repeated, they ended in a sacrifice of life.

Thus are we reminded, that, though many things may be accomplished, they should never be attempted—and that we should always avoid all rash and hazardous experiments. I do not wish to be understood as being hostile to all "experimenting and improvement," nor do I wish to be forever plodding and digging after something new. Well would it be for us all, if we would exercise a little caution and a study, and were less daring and adventurous. So much for an introduction.

At the commencement of the winter of '41, fearing that I had not sufficient feed provided to keep all my stock in good condition through the winter, I was forced upon an untried experiment,—of keeping my flocks of sheep on oats and straw. I am aware that sheep had been kept on grain and straw through a part of the winter, with success; still I was apprehensive of evil in feeding on grain and straw exclusively, through the entire winter—as they were ewes, of mature age, and with lamb.

I gave to a flock of 105, one bushel of clean or threshed oats per day, and what wheat straw they needed—fed in boxes. (For description and diagram see My No. of the Calculator.)

And now need I say, Mr. Editor, that when a boy I was shepherd, a young man, still a shepherd, for I fed my flocks! With an experience of 12 or 15 years in sheep husbandry, I am prepared to speak knowingly, (excluding all boasting) that I never knew a flock that were wintered on hay, that were finer in appearance and condition. The sheep, of course, were protected, their appetite at all times was good, devoting their food with great lucidity—consuming all, and using boxes, wasting none—and in candor, there was no appearance of sickness or disease among them, and their progeny were strong and thrifty.

And now let the credulous and unbelieving follow me a little farther, while I prove, I throw to their satisfaction, that sheep may be wintered more cheaply on grain and straw, than they can be on hay.

In my estimate of the expense of wintering a flock of 100 sheep, of mature age, I deem 12 tons of good hay barely sufficient, if fed as they should be; however, taking it for granted that it is enough, in few words, the account stands thus:

12 tons of hay, at \$5 per ton, \$72 00

I fed to the flock in question, (perhaps I should not omit to say they were high grade Saxons) 105, one bushel of clean or threshed oats per day—150 days—the oats were worth two shillings per bushel and no more.

150 bushels of oats at 25 cents, \$37 50

15 loads of straw, 15 00

\$52 50

We find, therefore, the expense of feeding oats to be \$52 50, and a saving of \$19 50,—a small item it is true, but worth looking after in these times.

I followed up my experiment of '41, and kept the past winter a flock of 750 of the same description of sheep, and succeeded equal to my expectations. Instead of giving them oats exclusively, I gave an equal quantity of bran, and again had a difference quite as great as before.

75 bushels of oats at 34 cents, \$25 50

75 do bran at 6 cents, 4 50

15 loads of straw,	15 00
Feeding hay in the same quantity and proportion as above, we should have used	\$45 00
9 tons, at \$7 per ton,	\$63 00
Making a difference of	\$18 00

The average price of oats this winter in Tompkins county, is 34 cents, and hay has sold abundantly for \$7 per ton. Another small item, you perceive, Mr. Editor, and if economy be the watch word of every farmer, then let us look to these things, and disregard them not.

Yours, &c.

C. M.

Ludlowville, May, 1842.

The above communication we consider well deserving the attention of farmers. Feeding upon hay exclusively must be considered, in respect to almost all animals, as the most expensive of all feed. A large portion of the stock in Great Britain we suppose is kept upon straw and turnips, and much of it fattened upon the same feed. It were very much to be desired that our farmers should raise some succulent feed for their stock, to mix, during our long winters, with their dry feed. On the ground of economy, as well as regard to the health of their animals, this may be strongly urged upon them. We have made repeated experiments in feeding horses and oxen upon cut straw and meal, and have found it a great saving, certainly a third of the expense, over the mode of feeding them with hay. We shall subjoin to Mr. Morell's account, a statement of Mr. Bard on the same subject, published in the Memoirs of the New York State Agricultural Society, vol. II, which is confirmatory of the results of the experiment detailed above.

Letter from W. Bard, Esq., on Wintering Sheep on Cut Straw and Meal.

MY DEAR SIR—Though late to do so, I will now answer the inquiry you make relative to the manner in which I fed my sheep last winter. I was fearful of wanting hay before spring, and determined to try the experiment of feeding a flock of one hundred wethers on cut straw and Indian meal. I began when they were first put up for the winter, and continued one pen of feeding till they were turned out in the spring on pasture. I allowed six quarts of straw and half a pint of Indian meal, mixed with water, to each sheep per day; it was fed at three times. Now and then, they had an animal of hay thrown to them, perhaps 2 1/2 wt. in the course of the winter. I lost none of them. When turned to pasture they were in good health, and apparently as active and strong as any other sheep. They sheared about three pounds of wool per head. Their bodies were not swelled like the bellies of my other sheep which had hay and water; they had no gummings I did not notice. Whether this was owing to the quality of the food, to their not being allowed enough of it, or to their not getting through the winter any water, excepting the little that mixed the straw and meal, I can not tell.

I have somewhat altered my plan of feeding this winter. I feed all my sheep—round once a day, in the morning, with hay, and give them meal and straw in the middle of the day and at night, allowing them two thirds the quantity of meal and straw per day which I allowed them last winter. I consider this higher feeding, and the mixing long and short feed may be an advantage. I shall be better able to say in the spring which I like best; at present my sheep look very well; they are fond of the meal and straw. One man tends 120, and cuts the straw for them.

I remain, with great respect,

Your obedient servant,

WM. BARD.

To G. W. Featherstonhaugh.

Winter Farm Management.

FRIEND BATHAM—Agreeably to your request and my promise, I herewith send you a few facts in relation to that subject of subjects, Agriculture. And I must here premise that in all my life I have written but three articles for publication, and that last year was the commencement of my farming operations. I was necessarily absent much of the season, consequently, as you will perceive, I am rather green in

both departments of the above named business. I make no pretensions to agricultural knowledge, except what I have learned from my numerous agricultural works and a few months observation, and as the result of which allow me to state a few facts, and first in relation to the manner in which I have wintered my stock.

This consists of twenty-six head of cattle, principally full blooded and grade Durhams, and twelve horses, nearly all thorough bred. Four of the horses have been worked and kept at hay and grain all the time, and two others part of the winter, the remainder of the entire stock have been securely tied up during the night under good sheds, and regularly fed twice a day; in strong plank mangers, with as much corn stalks, cut up at the roots, as they could eat; on which, after being cut up in a cutting box about one inch long and properly wet, has been put corn and cob meal, nicely incorporated with it, at the rate of four quarts to each animal daily, or about two quarts of Indian meal.

Perhaps some one will say that that amount of meal with plenty of good hay, would have answered just as well, and saved all the time and trouble of cutting and preparing the food; but hold on friend, we'll make a "pint" there. Hay is worth here fourteen dollars per ton. Now according to the usual estimate in such cases, my stock would have consumed about fifty tons of hay, amounting to, at that price, seven hundred dollars. My corn stalks were cut from fourteen acres of corn ground, when the corn was newly glazed, all sound and in good condition. The expense of carting the stalks to my barn I consider more than paid, in the advantage and pleasure of cultivating the crop the following year, when compared with the slovenly manner so often adopted in Ohio, in having a corn swamp in the field to clog the plough, confuse the team, and after the corn is ready to plough and hoe, at least two boys ought to follow the plough to act as rearmen, and to bind up the broken backs of the young corn.

But we will say corn stalks from 14 acres, at

\$5 per acre, 70 00

Five months, or 150 days feeding 32 head, 4 quarts per day each, corn and cob meal 600 bushels; corn worth here 25 cents,

120 00

corn and cob meal say 20 cents, Extra expense between cutting stalks and foddering hay 20 shillings per month for 5 months or 150 days,

12 50

Making the expense of wintering my stock on stalks and meal,

\$202 50

Which, when taken from the estimate above

of \$700, leaves the snug sum of \$498 00

Again, during the forepart of March I had a job of work which I wanted done with dispatch, and no time seemed to be left for cutting stalks, and I told my foreman to give my stock their usual quantity of meal with as much good hay as they would eat. This lasted about a week or ten days, and at the end of the time I was astonished when told by the wife of my foreman that the milch cows had decreased over one half in their milk. We immediately returned to the usual feed and with it returned the usual quantity of milk.

Again—a very important consideration, to me at least, is that my stock are all fat; many of them good beef; and I don't believe that with all the good hay they could eat, even with the above quantity of meal per day, they would have been in as good condition. Several of my ewes, which will calve in from four to six weeks, now give from six to eight quarts of milk daily. The beautiful patent cutting box which you sent me last fall, I consider one of the greatest improvements of the age; it has cut all my corn stalks

butts and all, together with much other stuff, and has never cost me a shilling for repairs. A man can, in one hour, cut 40 bushels with it; but this season I design getting a portable horse power, which, when attached to it, can cut up a small 'haymow' of corn stalks in a short time. And now friend, have I settled that "pint"—\$590 saved in hay—fat cattle, plenty of milk, lots of butter to sell every week at 15c. 6d. to 25c. per lb., while it is scarce, and any quantity of manure to return to that land which my neighbors told me I would ruin by taking off that cane brake, and fat tenants to draw it. I had designed mentioning other subjects, but as this has been extended beyond its designed limits, I must postpone their consideration until some future time.

I remain very respectfully yours,

JNO. W. SMITH.

Kaag's Farm, Maumee City, 1812.

The subjoined article from the Farmer's Gazette, published at New Haven, is entitled to particular attention as from one of the most intelligent friends of Agricultural Improvement in the state of Connecticut, upon whose carefulness and exactness in experimenting and reporting his experiments, entire reliance may be placed.—*Ed.*

USE OF PLASTER.

MR. STOKER.—In answer to the inquiry of your subscriber from Cheshire, as to the best time to sow Plaster of Paris, I will give the result of my observation and experience, and detail the mode and the time of its application, without in every instance stopping to assign the reasons, since that would render my communication of an unmeasurable length. By the way, the inquiry in its form, is as pertinent as it would be to ask, "when is the best time for a man to sneeze?" as if a man might sneeze but once a year.

A vague impression has prevailed that this article is of little value as a manure near the sea shore; yet no detailed experiments have been tried which all favor that idea. On the contrary, when they have been carefully made, results directly the reverse have been obtained.

The truth is, as suggested in the report of the Executive Committee of the Agricultural Society published in your paper last fall, and, as stated in the "Transactions of the Society for promoting Agriculture in Connecticut," referred to by you in your last number, too little attention is paid to the manner in which plaster is ground.

All the ground plaster I have been able to find in this city is brought in casks from Maine, and is little finer than sand. In that condition it is of trifling value.

Plaster will in time be dissolved in some two thousand times its weight of water; but if in that state in what time, if ever, it will receive the requisite quantity of water, in such condition and at such temperature as will dissolve it, I leave it to your readers to conjecture. One thing is certain, that it is of no value unless dissolved, since it is supposed that its utility arises in a great measure from its uniting with and absorption of ammonia from snow and rain. This it is evident it can not do while it remains in the form of sand. If however the article is perfectly floured—no ground so fine that it has a rich oily feeling and no grit can be perceived between the fingers, it is perfectly obvious to any one who will observe and reflect, that it is far better adapted for immediate and powerful effect. Not until plaster thus ground is proved by actual and careful experiment to be of no value on the sea coast, shall I at all doubt that the opinion which now prevails arises from causes here pointed out.

To me this is the more obvious from an examination of the extent of this opinion. Around our city, and so far in the interior as ground plaster is carried from here, this belief exists. Twenty miles northward, where the article is obtained from Mr. Moore's Mills in Berlin, in its most perfect condition for use, it is considered indispensable. So also in the western and north-western portions of the county, where it is procured from Derby, and is said to be well ground, it is used in very considerable quantities, and with evident benefit.

Plaster may be sown to advantage on meadows in the fall, where it is not liable to be washed away. It then combines with the ammonia in the snows and abundant rains of winter and spring. If not sown in the fall or winter, it is well to sow it upon a light snow if possible in the spring. Permit me also to remark,

that this is the best time to sow grass seed,—clover for instance, on grain lands sown in the fall previous, when from any circumstance it is not deemed expedient to sow the grass seed with the grain in the fall.

On the ground sown with grass seed, it is important that the young plants should receive the benefit of its application as early as may be in the spring.

Many persons have tried plaster on pasture grounds, and have found, as they think, no advantage from its use; and why? They sow a part of a lot on which cattle run at large, expecting of course the feed on the part thus sown to be much fresher and fuller through the season; but as they in fact find the herbage shorter and apparently less durable, they very naturally infer that the plaster does no good. More careful attention would convince them that there is more in this matter than they dream of. The cattle soon ascertain the part on which the plaster was sown, on account of the superior sweetness and succulence of the herbage, and are found feeding continually upon it. Thus I have seen beautifully illustrated on my own farm, by sowing in different years different lots out of a range in which stock was pastured. The cattle always made their head quarters in the lot which had received the plaster, and kept the feed short in that while it was abundant in the others.

On pastures it is also well to sow early, because of the more frequent rains of the spring. Some farmers, however, whose pastures are abundant in the spring, and early summer, reserve their plaster until near the close of summer in order to induce a fresh growth for fall feed. Many also, who have tried sowing early in the spring, and also in the fall, think that they derive more advantage in that way, than from sowing an equal quantity at one time.

Seed corn should be soaked in a solution of sulphate and rolled in plaster. As soon as it is fully up, the corn should have a careful hoeing, and about a teaspoonful of plaster to each hill, or about one bushel to the acre. It should be scattered round the corn as much as is convenient in putting it on. If sown broadcast, the immediate effect is less, but the final result is about the same.

Pointers should either be wet and rolled in plaster, or a small quantity should be thrown into the hill upon the seed before covering. Here I can not but beg of our farmers not to expose their seed pointers to the rays of the sun, even for a single hour, since, unless the land be moist or the season prove exceedingly wet, the crop may be entirely ruined by so doing, and will under any circumstances be greatly retarded and lessened. Pointers are benefited by larger quantities than are requisite for corn, and the application to them after hoeing should be liberal. From my own experience, and that of my neighbors, I consider plaster indispensable for this crop.

The farmers of this county are yet to learn the secret of raising potatoes, if, as I am led to believe, the average crop is less than two hundred bushels. Five hundred bushels have often been obtained from the acre in other parts of our state; and why not in this county? Some of our best land ought to produce as much as any other.

I have never perceived any beneficial effects from the direct application of plaster to rye, oats, or wheat, although those crops have been exceedingly fine on land which had previously been improved by the liberal use of plaster.

Turnep seed may with advantage be mingled with plaster at the rate of one bushel of plaster to the acre, and be sown broadcast in the field. The crop will be greatly benefited, and the seed easily and evenly sown if due care is exercised.

Plaster may also be used with great benefit on buckwheat. The seed should be prepared as seed corn, and plaster should be sown broadcast upon the young plants as they appear.

From a series of experiments in my garden last season, with plaster saturated with urine, I am satisfied that a great accession of the most powerful manure may be made to the farmer's stock, by strewn plaster in stables and elsewhere, so as to absorb all the urine. In this way, if his manure when thrown from his stable is protected from the rain, even by a sled only, he may obtain a great amount, little if any inferior to the best good podrette which sells at two dollars the barrel.

I wish it to be distinctly understood, that when I recommend Plaster of Paris, and speak of its effects, I refer only to that which is ground so fine as the finest flour. No other, as I view it, is worth the trouble of putting on to the land.

CHARLES ROBINSON.

New Haven, March 23d, 1842

White Weed, or Ox-Eyed Daisy.

MR. EDITOR.—Will you or some of your correspondents have the goodness to inform me of the best method of exterminating white weed from fields and pasture lands?

A YOUNG FARMER.

We know no better way than to cultivate the land a year or two, and then lay it down with clean seed. In a barn yard where this weed is mixed with the hay that is used, the manure will of course be filled with the seed; or where manure is purchased from city stables, as in the neighborhood of Boston for example, where this weed abounds, this manure is undoubtedly in many cases surcharged with the seed. If the land is cultivated with corn for example, and kept thoroughly clean, and the ensuing year sowed with grain, without manure, and laid down as we observed above with clean seed, it will be mainly extirpated; but if any appears among the grass, we know no other way than to root it out thoroughly as fast as it appears by hand or hoe. Some farmers do not object to it as hay. Cattle and horses will eat some portion of it when cut early; but its free growth very much diminishes the crop of hay; and putting before them the best mixture you can find of herbs-grass, red-top and clover, and an equal quantity of white weed in the best cured state, and we think they, brutes as they are, will have no difficulty in making a choice. We in such cases, if left to us, should be very apt to follow our nose.

Swiss Bulls and Cows.

The Swiss Cows have been much celebrated for their milking qualities, and a friend of ours, who has resided in Switzerland, has spoken of them in the most extravagant terms as exceeding anything known. We concluded that he had never stood by the pail and that his glasses were of the very highest magnifying power. Another friend of ours, from these representations, was induced to write to Fellenberg, at the celebrated school at Hofwyl, in order to procure some of this stock. The difficulty of procuring and sending the animals at that time, prevented the success of the application. From Fellenberg's letter, which was at one time in our possession, we inferred that the statements commonly made of their yield, were not a little exaggerated; and the product of the cows, though very large, was not unsurpassed. If we understood the measures, their average yield in the best of the season, was about sixteen quarts per day, and from seven to eight quarts through the year. Fellenberg seemed to have no disposition to exaggerate their good qualities. The breeders in England will, beyond a doubt, bring them to a fair trial, and determine the question of their superiority.

"Swiss Bulls."—We are authorised to make known, that four first rate two year old Swiss bulls, purchased for Sir Francis Mackenzie by Professor Agassiz, of Neuchâtel, and which, after a search of many months by the best judges, were selected without regard to any limitation of price, as the very best all Switzerland could produce, are now on their way down the Rhine for London, where Sir F. has desired that all amateurs may have an opportunity of seeing them. Two of them are destined for Scotland; the other two Sir F. wishes to dispose of in England, at whatever may be deemed a fair price, even should he not be remunerated for his expense and their cost, as he feels certain from what he has often seen in Switzerland of the beauty of their two breeds of cattle, combining great milking with fattening qualities—a thing so very desirable—that their blood could be crossed most advantageously to the improvement of our short-horns and other breeds. The best proof of their milking quality is, that no other cow is kept in Lombardy at so low a price as these making dairies—and their shape will be seen by all good judges to show good fattening qualities. They will leave Basle about the 15th of May by steam, and may be expected in London about the 20th. Mr. P. Hanbury, letter, 15 Albany, will give information as to where they can be seen, or at 60, Lombard-street. They can remain in London but a very short time."—*Chateau de Talhouet, May 6th, 1842.*

HATCH'S SOWING MACHINE.

Having disposed of quite a number of these machines during the past season, they are now becoming extensively known, and the demand for them is rapidly increasing; the inventor has therefore increased his facilities for manufacturing, and is now prepared to furnish machines to order, at short notice. Every farmer is aware that sowing of grain by hand is one of the most laborious and difficult operations of his profession, and one which but few men can perform correctly. This machine will sow all kinds of grain, grass seed and plaster, at any desired rate, from four quarts to four bushels per acre; and a man or smart boy, with a horse, will sow 25 acres per day. Besides the saving of time and labor, the product of the crop is increased by the perfect evenness with which it deposits the seed. The machines are made in the best manner and warranted—price \$40.

It should here be observed that two or three of the machines first sold in this region were somewhat defective, and a few individuals may in consequence have been prejudiced against the invention. Others have complained that the machines would not sow deep plaster, but the inventor assures the public that this, and all other objections, are now obviated, as he will convince those who will apply to him.

State and County Rights will be sold on very favorable terms to any enterprising mechanics. Any infringements will be strictly attended to. All letters must be post paid. Address

JULIUS HATCH, Rochester, N. Y.

Instead of publishing the numerous and highly respectable certificates and recommendations which might be obtained, the inventor respectfully solicits farmers to call on any of the following well known gentlemen who possess the machines.

Rawson Harmon, Jr., Sylvester Harmon, Elisha Harmon, Henry Rogers, Daniel Rogers, Isaac Cox, Woodland.

T. H. Newbold, Caledonia.
Isaac Lacy, Chili.
Mirvin Smith, Mendon.
H. Fellows, Samuel Miller, Penfield.
John Moxen, Asa Rowe, Greece.
Chester Scott, Elm.
Alva S. Hoyt, Brant.
Jesse Adams, Rostford.
Jacob Clapp, Rush.
Aaron Burke, Igha.
H. Morrison, Parma.
David Brooks, Avon.
Wm. W. Corban, Canandaigua.
P. L. Buncel, Victor.
J. W. Smith, Monroe City, Ohio.
John Johnston, Florence, Mich.
T. C. Leggett, Glens, Ill.
J. M. Sherwood, Auburn.
As Mr. Hatch is not very extensively known, I

cheerfully state that from an intimate acquaintance of the year past, I believe him to be a man of honor and integrity; and having repeatedly seen his machine in operation, I do not hesitate to pronounce it the best machine in use for the purpose. I have also conversed with several farmers who have purchased and used them, and they express the highest satisfaction.

M. R. BATHAM.

Rochester Seed Store, June, 1842.

HUSSEY'S REAPING MACHINE.

Having had frequent communications from Western Farmers, to know if I could not deliver my Reaping Machine in Rochester for \$120; I would inform them that I have two now in Rochester, which can be had for that price, by calling on J. B. Cox, Watts & Co. Orders for others at the same price will be duly received.

THOMAS R. HUSSEY.

Argues, N. Y. June, 1842.

ROAD OR DIRT SCRAPER.

May be had at the Rochester Eagle Furnace. Price wood-lined, \$5. No. 200 without wheeling, \$2.50.

A. J. LANGWORTHY.

Ruta Baga and Turnip Seed.

A NEW supply of genuine imported purple top Ruta Baga Seed—also a full assortment of English and Scotch Turnip Seeds, for sale at the Rochester Seed Store and its agencies.

WHITE DUTCH (LOVER SEED), a fresh supply, received at the Seed Store.

SILK WORM EGGS, of the large Sulphur and Peanut varieties, for sale at the Seed Store \$1 per ounce.

June 1. M. B. BATHAM.

Garden, Field, and Flower Seeds.

THE subscriber having established a large Seed Garden about one mile from the city, on Monroe Street, would say to his old customers and other, that he is prepared to receive orders for seeds, at wholesale or retail, on the most reasonable terms. By his long experience in the business in the Shaker Seed Garden at New Lebanon, and a determination to offer seeds as good as such as are raised under his immediate inspection or imported from the most respectable establishments in Europe, and their vitality carefully tested, he is therefore confidently expected to give complete and satisfaction to all who may favor him with their patronage.

Orders for Fruit and Ornamental Trees, Flowering Shrubs, and Green House plants, promptly executed in their season. Selection made by the proprietor when requested.

Rochester, June 1. C. F. CROSMAN.

Rochester Plough Manufactory.

A NEW and superior kind of ploughs of the most approved patterns, such as the Genesee, Cayuga County, Gibson's, Woods', Reids' Side Hill and Stager ploughs, also, Cultivators, Reversing Horse Rakes, Road Scrapers, and Hand Wheel Ploughs.

June 1. C. P. D. WRIGHT & CO.

PLOUGH.

A NEW and SUPERIOR KIND OF PLOUGHS, (two sizes) designed for breaking up summer fallow, may be purchased at the Rochester Eagle Furnace—price \$4 and \$7 each. Wood and other produce taken in exchange.

A. J. LANGWORTHY.

WHALE OIL SOAP—for destroying Bugs and Insects in Gardens, (see New Genesee Farmer, Vol. 2, p. 112) For sale at the Rochester Seed Store.

Remarks on the weather and progress of vegetation, commencing June 26th and ending July 25th.

June 26th, shower at 2 o'clock, P. M., with thunder and wind; 27th, thunder this morning at 6; 29th, thunder showers in the evening; 30th, showers with thunder at 5 o'clock, P. M.

July, the seventh month of the year, so called from Julius, the surname of Cains Cesar, who was born in this month. Before that time, this month was called Quintilis, or the fifth month from March.

July 1st, rain; 2d, rain in the forenoon, clear in the

afternoon; 3d, a shower with thunder at 6, P. M., Aurora Borealis this evening; 4th, fair; river high; 7th, farmers have commenced haying; 8th, thunder showers at 1 and 2 1/2 o'clock, P. M.; 9th, very rainy last night; clears off this afternoon; 14th, a little sprinkle; no rain from the 15th to the 24th; 24th, thunder showers in the morning.

Corn is small, but has grown very fast for the last 10 days; corn in silk the 16th; last year it was in silk much earlier. Farmers commenced harvesting about the 20th; green corn in market last year the 16th of July. Whortleberries were in market the 13th. Chestnut trees in blossom the 5th. Tomatoes were ripe the 26th. I have seen no green corn, nor whortleberries, nor tomatoes in market yet.

Chestnut trees in blossom the 20th, much later than last year.

Note.—Venus is now the evening star, and may be seen in the west a little after sunset. Jupiter and Saturn may also be seen; they come to the meridian about 11 o'clock in the evening. Jupiter shines with a white light and is very brilliant. Saturn is of a dim reddish color and comes to the meridian a little before Jupiter.

Royal Agricultural Society of England.

"At a meeting of the Royal Agricultural Society of England, on the 18th of May, in London, on motion of the Duke of Richmond, seconded by Earl Spencer, Prof. Justus Liebig of Giessen, Germany, and Mr. Henry Colman, Agricultural Commissioner of Massachusetts, were unanimously elected honorary members of this Society."

Mr. Colman gratefully appreciates this distinguished honor; an honor much higher than any to which his ambition had ever aspired; and the more highly valued on account of the eminent friends of agriculture at whose instance it has been conferred. Viewed aright, it can serve only as a new stimulus to render oneself deserving of it; and quicken efforts, however humble, to be useful in a cause deeply and inseparably connected with the physical comfort and the moral welfare of mankind.

Agricultural Papers.

In noticing the American Agriculturist in our last number, by an inadvertence we stated that each number consisted of 16 pages. We should have said 32 pages imperial octavo. We are happy to make the correction, as it gives us another opportunity of commending to our readers a publication ably conducted and promising much advantage to the agricultural community. It is published monthly by Geo. A. Peters, New York, and edited jointly by A. B. & R. L. Allen; price one dollar per year.

The cheapness of agricultural publications is a remarkable feature of the times. The American Farmer, the agricultural pioneer, was published at Baltimore for five dollars per year and liberally sustained. Now a New York Farmer, without going out of the State, to which, we hope he will not confine himself, may have the Albany Cultivator, one of the best papers ever printed, the American Agriculturist as

above, the instructive Central Farmer from Rome, and our own humble sheet, which we do our best to make useful, for three dollars per year. To these he may add the excellent and highly useful paper the Northern Light, printed at Albany monthly, and United States Farmers' Journal, printed in New York city, under the able and experienced supervision of Fleet & Blydenburgh, for a trifle more. Few New York farmers, who have a hundred acres of land, are excusable if they do not take all of them; and if they cannot read them themselves, circulate them among their neighbors, in the public schools and reading rooms. How can they do a better service for the cost? Yet strange to say there are many who will not aid us at all; and there are others who threaten to withdraw their patronage, if we happen to differ from them in opinion. There are too, some patterns of liberality and justice, who want to beat us down from 50 to 25 cents. Exquisite magnanimity! men, a million of whose souls could make together a Somerset through the eye of a fine cambric needle without bruising or jostling or crowding. Out upon such meanness! We remember one day, in Boston market, buying of a farmer, who had come two hundred miles, some lump butter as fine as could be made, when one of these folks came up to inquire the price. The current price at the time was from 17 to 20 cents. The reply of the farmer was 12 1/2 cents. Why, said the man, wishing to "beat him down," don't you think that's high? We could not restrain our indignation.—"Throw it at him! throw it at him!" said we, "such a fellow ought to have his broad spread with wheel-grease."

A Liberal and Useful Movement.

The Livingston County Agricultural Society have offered 20 vols. of the Cultivator and 20 do. of the New Genesee Farmer, to be given as gratuitous premiums to the deserving. Allow us to say this is highly creditable to their good judgment. If we recollect aright, the Rhode Island Society for the encouragement of Agriculture and Manufactures, have been accustomed for years to take fifty copies of the New England Farmer for this purpose.

Important Notice.

There is a large amount due us from Post Masters and Agents in the Western States and elsewhere, mostly in small sums it is true, but our whole resources depend on such small sums, and therefore we hope no one will delay sending on that account.

¶ One word to our friends.—We have a large supply of back numbers of the current volume on hand, which ought to be in the hands of subscribers. Will you not help us—would you not be doing your neighbors as well as ourselves a real kindness, by soliciting them to subscribe? The currency is now considerably improved, and bills of most of the states will answer for remittances.

The Stupendous Temperance Reform.—Such is the progress of this reform that the most credulous and enthusiastic laborer in the cause, has been struck dumb by its all-sweeping progress; while the more sceptical looker on, is heard to exclaim, that God is performing a miracle for the cleansing of a leperous generation.

S. W.

Scientific Agriculture.—Letter V.

MANURES.—URATES; FOUDRETTE; GUANO.

One of my chief designs in these letters is to endeavor to elevate the mind of the agriculturist, by bringing him constantly and repeatedly in contact with the higher branches of the pursuit he follows. The names Oxygen, Hydrogen, Nitrogen, &c., may appear at first puzzling to him, but by frequent collision with them, and by the persuasion that they represent substances as distinct, although not quite so tangible, as his own plough or harrow, this appearance will wear off, and he will be gradually brought to pay attention to their operations. When he becomes convinced that the ammonia in his dung heap is its most valuable part, he will exert himself to economize and save it in every possible way. When, by practice and experiment on his own farm, he becomes intimately acquainted with the powers on *his own soil* of the different artificial manures, of nitrate of soda, of Guano, or of the composts under various names now regularly offered for sale as manures in this and other countries, then will he discover the great value of the study of those principles and laws, which, always found to be simplest when best understood, nature has wisely ordained for the regulation and connection of the animal and the vegetable kingdom; a kingdom in the midst of which the farmer passes his whole existence, and in whom, therefore, an ignorance of these laws is only to be excused by want of the means of obtaining a knowledge of them. I will then, at the risk of repetition, and in order more clearly to elucidate what follows, recall a few facts and principles already set forth in these letters, and which cannot become too familiar to every one connected with agriculture. They are that vegetation is chiefly composed of carbon, oxygen, hydrogen and azote or nitrogen, and that this latter substance is principally useful in promoting the digestion of the food absorbed by the vegetable, or in other words of converting this food into its substance and juices; assimilation, as it is most properly called; hence that if a vegetable absorbs more food than it can procure nitrogen to assimilate, all such superabundance is worse than useless, it is injurious. From this it will be seen that during the whole time a plant is growing, (which is this action of assimilation) until the formation of the flower and the fruit, it is necessary that azote should be supplied just as fast as, and for economy not faster than it absorbs its food; that the more of this food is healthily digested or assimilated by means of azote, the larger will be all the parts of the plant, and the greater will be the quantities of saccharine and other juices stored up in the stems, roots, &c., for conversion into flower and fruit, and the larger and finer of course will this flower and fruit be, provided the necessary heat and sun light to ripen these juices be present, and the requisite arrestation of growth of stem and foliage take place as prescribed by nature previous to the formation of these products.

This statement renders quite clear the importance of a constant and abundant supply of azote to vegetation, and will therefore shew the value of urate as a manure. Urine is composed chiefly of Urea with a few extremely useful salts, as sulphate and nitrate of potash, common salt, phosphate and acetate of soda, a little phosphate of lime, and a little muriate and urate of ammonia.

Urea, the chief ingredient of which is uric acid, contains in 60 parts, 19 of Carbon,
25 of Nitrogen,
4 of Hydrogen,
19 of Oxygen,

60

Uric acid contains in 100 parts

36.11 of Carbon,
33.36 of Nitrogen,

231 of Hydrogen,
28.19 of Oxygen.

100

This uric acid combines with various alkaline bases, such as ammonia, soda, potash, &c., and forms salts called urates, thus urate of ammonia, urate of potash, &c. Now one great feature of these urates is their slow solubility in cold water, although some of them particularly urate of ammonia, is very readily soluble in hot water; this is as though nature had said in stamping them with this property, "You are required to supply digestive powers to vegetation, and your quality must be to dissolve only just as fast as you are wanted." We shall see hereafter the value of Silex, Lime, Potash, Soda, &c., with their different salts; on these much discussion does and always will exist; they are all good applications when the soil does not already contain a sufficient quantity of them; but no discussion ever arises respecting animal manure containing nitrogen, no farmer, whatever may be the quality of his soil, ever doubts the value of this—on this the only discussion which arises is as to its economical application. In our Chemical Laboratories by the application of fierce fires, of concentrated acids and alkalies, we can analyze various substances and exhibit to our limited senses their constituent parts, and in many cases we can gain some knowledge of their properties; but nature does not act thus, yet she analyses and separates the same ingredients, by action on infinitely minute particles, such as are entirely invisible to our most powerful microscopic efforts. We analyze for exhibition, she for use. She analyses or forms combinations, and again separates these into their original particles, just as they are wanted by the animal or the vegetable creation, but of her methods of so doing we are at present profoundly ignorant; our chief exertions must be confined to observe her operations and afford ample ingredients for carrying them on. Thus soon after animal urine is voided it begins to ferment; urea and urates are formed; these, applied to the soil, are acted upon by plants, and their constituent parts, nitrogen, oxygen, &c., with their alkaline bases, are separated by them for their growth. The immense value of this material is therefore quite evident, as is also the folly of wasting it. The great practical knowledge now required, is to find the best way of preserving its virtues until wanted for use, and the quantities in which to apply it with the utmost economy and advantage on soils variously constituted. Much experiment is still needed to advance the present infancy of this great practical study. There is a substance existing in immense beds of 60 to 100 feet in thickness on the coast of Peru, called Guano, pronounced something like Huano, with which the people of that country have time out of mind manured their almost barren, sandy soil, and by the help of which they have raised good crops of corn. The recent application of science to agriculture, has caused this substance to undergo investigation for the purpose of ascertaining its value as a manure. Amongst much other valuable information contained in a recent publication of Dr. Dana, of Lowell, may be found the latest and most correct analysis of Guano by Voelckel. It contains in round numbers, About 31 per cent of ammoniacal salts, (amongst them urate of ammonia.)

About 14 per cent of phosphate of lime, the chief ingredient of bone dust.

About 31 per cent of organic substances, such as will form humus or geine.

About 20 per cent of salts of soda, potash, magnesia and lime.

About 4 per cent of sand and clay.

So that according to our present knowledge, it would hardly be possible to concoct a compound of greater apparent power on vegetation. Its operations have

consequently been found so valuable in England, that about 60 vessels are now employed in removing it there from Peru, and it has taken its place in the price currents of that country as an article of standard value. The London price current of the 24th May, observes, "Guano is now dull of sale, though offered at the reduced price of £15 to £16 sterling, about \$60 to \$64 per ton" of 2240 lbs., it used to sell for about \$50. Notwithstanding its immense quantity, it can hardly be any thing else but the excrements of birds, urates never having been found naturally formed, except in animal excrement. It will be observed to contain many of the ingredients of urine. I am not aware that any experiments have been yet made on this substance in this country, but having, by the kindness of a friend, received about a pint of it, just arrived here direct from the coast of Peru, I have applied it to different plants in quantities varying from one sixteenth to one hundredth part of the soil. Two or three plants of delicate habits to which the smallest quantity has been applied, have in 14 days been killed by its too great power; other plants of more robust habit, are evidently getting of a deeper green color in their leaves—all have been most copiously supplied with water. Dr. Lindley, in the London Gardeners' Gazette, states that not much is yet known there on the subject, but advises trials to be made by solutions of it in water; this method, however, is evidently inapplicable to large agricultural operations, besides it is dissolving out the soluble salts and applying them alone by themselves—whereas by intimately mixing with the earth and copiously watering, the roots can act on the substance in the way most congenial to their nature, and the salts are also dissolved. The best way, probably of using it on a large scale, would be either by mixing it thinly spread throughout the manure heap, or strewing it scantily over the ground previous to ploughing. From its intense smell and appearance, it must be a very strong manure, but to what vegetation it will be most advantageous, and how best applied, will require some experience to decide upon. Other artificial manures called Foudrettes, are now commonly known here; they are or ought to be chiefly compounded of night soil with or without animal offal, prepared so as to retain the ammonia, which, although not the only, is yet the chief valuable ingredient. It is obvious that its effects will depend on the proper preparation which it undergoes and on its freedom from adulteration of other substances of little value as manure.

Nitrate of soda, with several other salts of importance in commerce, are found in large quantities in the province of Ttrapaca, Peru, where it never rains.—This district has been visited by Mr. Blake of this city, and much valuable intelligence obtained. Dr. Daubeny, well known in England for the unremitting application of his scientific attainments to the promotion of agriculture, is about quitting England for the purpose of visiting this spot; so that agriculturists may perceive that scientific persons are every where bending all their energies towards the improvement of the cultivation of the soil: it behoves them, therefore, not to be behind hand in endeavoring to second, by their practical experiment, the efforts of these worthy co-laborers. J. E. T.

Boston, July, 1842.

Additional on Daniels' Patent Manure.

In my last letter I gave you my ideas respecting Mr. Daniels' new manure; since then, I have received the specification of the patent; here it is a little abbreviated.

The substances are divided into three classes: First: Ligneous matters, (say sawdust of any wood) also peat, straw, and weeds of any kind.

Second: Bituminous matters; these are, mineral coal, (not anthracite, I am sure, although this is not so

stated,) asphaltum, pitch made from coal tar or other pitch, mineral resin, and also tar.

Third: Animal matter, such as butchers' offal, graves, flesh of any dead animals, also fish.

The ligneous matters are ground to powder—or the same effect may be produced on them by mixture with caustic (unsulphated) lime.

The bituminous matters, when brittle, are ground into powder by machinery; but if sticky like pitch, a small quantity of dry quicklime is added to prevent their sticking to the machine. When these bituminous ingredients are liquid, they are converted into vapour by dry distillation, with which vapor the ligneous matters are saturated. These ligneous matters may be, spent tanners' bark, dyers' spent wool, sawdust, &c. The soft bituminous matters may also be reduced to a state of minute division, by being rendered soluble in water by the addition of caustic alkali—and in this solution the ligneous matters are steeped.

The animal matters are mixed with pulverised ligneous or bituminous ingredients before mentioned, and are then ground into fine powder.

This manure is deposited in the ground with the seed by means of a drilling machine, or scattered over the ground broadcast.

The words within bracket are my additions.

It will be immediately perceived that the particulars in this patent are calculated more to conceal than to disclose the real method of concocting this manure. Still, as the patent right would be vitiated unless all the ingredients were mentioned, there is no doubt that every substance used is given, and that the sulphur, of which I did not see the use, is not amongst them.

There are two ways in which this preparation may be made. The bituminous matters, any or all, may be dry distilled, that is, inclosed in an iron retort and acted on by fire, the ligneous substances exposed to the vapour proceeding from this distillation, and thoroughly saturated with it. Coal gas, for illuminating cities, is produced by dry distillation of bituminous coal. This method, however, would require a regular manufacturing establishment with proper machinery.

When peat, weeds, &c., are used, then with the tar and liquid bituminous matters, they may be operated on by quicklime, and sawdust added,—either of these mixtures, with finely divided animal matters, would no doubt make a rich manure. The principles of the formation of this new manure of Daniels', seem to agree pretty well with those I have laid down—namely, that all ligneous matters containing the basis humus or guano, a source of carbonic acid gas, well saturated with azote, particularly in the form of ammonia, and mixed with alkaline bases, as lime, potash, or soda, are highly important manures, particularly on light sandy soils; and that animal and carbonaceous matters are excellent ingredients to produce this saturation of azote.

Also, as a general rule, that whenever any rich manure, as cow or horse dung, is put on a hill on which plants are to be set, it is an excellent plan to mix a little quick lime with it before covering up. The lime liberates the ammonia, with which the earth around becomes impregnated, and the roots then find their proper food with its digestive power ready for them in abundance. The only precautions necessary, are to guard against the lime coming into contact with the roots, and also to cover up carefully, so that none of the ammonia may escape into the atmosphere.

J. E. T.

Reuben Miner, of Peacham, Vt., has this year produced 612 lbs. of sugar from 80 trees. The sugar producers of Louisiana represented to the Committee on Manufactures, that they cannot produce sugar at less than 5½ cents per pound. If true, the farmers of Vermont can compete with them at a profit.

From the (London) Mark Lane Express.

LIME.

There seems to be a growing difference of opinion as to the state in which lime should be applied to the soil. We have always been of opinion that lime, generally speaking, operates upon the soil in two ways, namely, chemically and mechanically; when it is merely to operate mechanically, as to lighten heavy clay soils, it is of no moment whether it be applied in a caustic state or not; but when intended to act chemically, we hold that it must be applied in a caustic state. We can speak of our own personal experience as to the practice on a very large district, many thousand acres of reclaimed land in the West of England, where lime was the article generally used in the first instance to stimulate the land to fertility. The lime is deposited on the land in heaps a perch apart each way, the heaps of course varying in size according to the quantity per acre intended to be applied, but ordinarily one bushel in each heap. It is then covered with a portion of the soil, and suffered to remain until it begins to slake into powder, and which of course varies in point of time according to the dryness or moisture of the weather; the heaps are then turned, and suffered again to stand until the small impurities are slacked, when it is spread upon the soil whilst yet in a caustic state, and immediately well harrowed into the soil. That it is more effective in a caustic than in an effete state, has been frequently proved in cases where, from some cause, two or three rows in a field have been suffered to remain uncovered, and by being exposed to heavy rain, was run to mortar before spreading; in such cases the difference has been manifest in the crop. We know it is the practice in some districts to mix the lime with head lands, ditch scrapings, and any other mould that can be collected, in large heaps, turning it over, and in due time carting it on the land. The operation of the lime, however, in this mode, is precisely the same as in the mode first described, with this difference, that in the former method the immediate effect is on the soil of the field, in the latter on the soil collected in the heaps with which it is mixed. It has been said that, inasmuch as lime in a caustic state has been found not to be injurious to animal life, it therefore would produce no effect upon the soil; abstractly this may be true, but it is the application of moisture which causes it to operate on the soil, and where water applied in proper quantity, it would immediately become destructive to animal life. This subject is one of great importance to the farmer, and we would strongly recommend those who desire information upon it, to read a chapter on lime in a "Treatise on Manures, their nature, preparation, and application," by John Donaldson, just published by Baldwin, in which the question in all its bearings is treated in a clear, systematic, and practical manner. This chapter is forty pages in length, and forms the best essay on the subject with which we are acquainted, and such as we can with confidence recommend to our readers.

Use of Camels on the Western Prairies.

MR. EDDER—The writer of this is a native of Russia, and has spent many years of his life in that portion of the Empire which borders on the Ural and Volga Rivers, north of the Caspian Sea.

I have, during the last two years visited, many parts of the United States; lately I have been in Missouri, Iowa and Wisconsin, and during my journeyings have had the fact strongly impressed on my mind that the Camel would prove a most valuable animal for burden in those prairies, and especially for traversing the country west even of the States I mention, where water is sometimes not found for days.

Camels used only for voyaging, possess great speed, and in the unsettled country would be found good to carry mails and convey intelligence. Their speed is great, 120 miles being a common day's travel for speedy animals.

Some individuals have expressed to me doubts of their being useful in this latitude. I mention the place of my birth only to show the most doubting that, in a more rigorous clime, they are extensively used. The breeding of camels is not more expensive than horses.

You no doubt are informed with regard to this subject, and I am convinced can give to persons desirous of breeding the camel, valuable information through the medium of your journal. They (the camel) can

be obtained on the Black Sea, and if Agricultural Societies would import a few pairs, they would confer a great advantage on this country.

From 600 to 1000 pounds, with a rider, is a common load for the camel; and the commonest herbage, even weeds and twigs, will suffice for their sustenance while enduring the severest labors.

I was advised by some gentlemen, to whom I casually mentioned this subject, to write to some editor of an agricultural paper of this matter, and being about to go to the east through Canada, have thought best to write to you from this place.

Yours, with respect,

H. BOHLIN.

Buffalo, July 6th, 1842.

The statements in the foregoing letter certainly deserve attention. The facts given in respect to the speed of the camel, their strength and capacity for burden, their endurance of fatigue, and the cheapness of their support, are well established. They are as susceptible of training as the horse. They are of a mild and peaceable disposition, and live to a great age. We had supposed that they could not endure our climate, but the statement of the writer of this letter shows that it is otherwise. That they would be useful on the prairies and in the long journeys now constantly undertaken in the vast and unsettled plains towards the Rocky Mountains, into Mexico, and other territories, now and likely to remain impenetrable by carriages, it would seem but reasonable to believe. On first reading this communication, we were disposed to regard it as mere matter of romance; but upon reflection we cannot but think it is worthy of consideration. The only great difficulty would be in first importing them. This has been done, however, in several instances; and with proper care and management, the race might, for any thing we can see, be as easily extended as the race of oxen or of horses.—Ed.

Native Silk.

The Cincinnati Gazette gives the following statement of facts showing the progress of the silk business in this country, as indicated by the bounties annually paid in the several States:

"In Ohio the bounty paid to silk growers in

1839 was.....	\$71 10
1841 was.....	2681 76

The whole amount of reeled silk produced last year is set down at 3000 pounds. In Massachusetts the bounty paid is

1836 was.....	\$85 20
1839 was.....	439 99
1841 was.....	4675 10

In New York, the increase in the quantity of cocoons produced, has been very rapid, in 1840 being 2000 pounds, while in 1841 it was 6426 pounds.

In Pennsylvania, the bounty paid is

1840 was.....	\$2101 80
1841 was.....	4418 55

The Rev. Frederick A. Ross has probably raised more silk than any other person in the country. During the last year he sold 300 pounds of reeled silk in Burlington, N. J., for \$1600. A silk filature has been recently established in Philadelphia."

Wool and Protection.

Your memorialists respectfully suggest, that the introduction of every yard of broadcloth into this country, is the introduction of two and a half pounds of wool into the country,—and the introduction of every yard of beaver and pilot cloths is the introduction of from three to four pounds of wool into the country, and each such yard of cloth foregoes the income of an acre of land of the American farmer, and of course employs the acre of land of the foreigner.

As citizens of this great Republic, we are entitled to our own market; we are entitled to the cultivation of our own lands—to the employment of our own labor; these are not unreasonable privileges, and to deny them is to destroy the arts of peace and prosperity.—Manufacturers' Memorial.

On Daniels' Artificial Manure.

The subjoined communication refers to the remarks of our correspondent J. E. T. in our July number. These remarks it will be seen are in some measure qualified in his communication of this month, made after having become more acquainted with the actual constituents of this celebrated manure. We give place to this communication from the highest authority, with great pleasure. Dr. Dana's valuable book, the *Muck Manual*, has not yet received that attention in our columns which is due, and which we design to give to it. This is owing to repeated disappointments in "promises to pay" on the part of our correspondents. In that book is illustrated more fully the "action of carbonic acid" upon silicates, which Dr. Dana refers to in this letter as of so great importance. We shall presently give his views of it more at large, leaving to others to determine how well they are founded.

Of this book, the *Muck Manual* for Farmers, by S. L. Dana, we find the subjoined notice in the July number of *Silliman's Journal of Science*, which we have no doubt is from the pen of Professor Hitchcock.

"In conclusion, we can cordially recommend this work to our agricultural friends for its practical character. It is not saying too much to assert, that Dr. Dana has done for the farmer in this treatise, what Dr. Bowditch did for the sailor when he published his *Practical Navigator*. In this respect this treatise contrasts strongly with such a work as that of Liebig on the Organic Chemistry of Agriculture, &c., which, notwithstanding its originality and the philosophical beauty of its theories, is apt to make the impression upon the farmer that he is not at present to expect much from agricultural chemistry but ingenious conjecture. We are sure that Dr. Dana's work will remove this impression, while on the other hand, the chemist will see in it evidence of the rapid advance of this science. Within two years, three able European chemists, Liebig, Daubigny and Johnson, have given to the world most mature and valuable opinions upon it; and now we have a *cis-Atlantic* effort, which will not suffer by a comparison with any other. Truly the genius of agriculture may exult in the bright prospects that are opening before her."

DEAR SIR—The remarks of your correspondent J. E. T. on the "new manure," like all things from his highly gifted pen, are of great value. He does not, however, seem to go to the root of the matter. After showing the value of ammoniacal liquor from gas works, he supposes that the "new manure" may be an attempt to form a substance or mixture, which resembles pit-coal; that this evolves ammonia, by spontaneous decay, as coal does by dry distillation. This is his explanation of the action of the new manure. It is good as far as it goes; but attributes too much to ammonia. When we consider the very small proportion which nitrogen forms of the whole mass of vegetable matter, averaging about 0.173 of the whole mass of cultivated crops, seeds, roots, stalks, &c., when green, and that whatever may be that proportion, nitrogen forms only 14-17 of any portion of ammonia, the quantity of this element, formed by the proportion of the new manure said to be used, must be quite too small to exert such effects as are said to be produced by its use. The proportion of nitrogen in coal is rated too high by J. E. T. Dr. Thomson assigns, according to Henry and Ure, quite too small a portion of oxygen in coal, while his quantity of nitrogen, though estimated according to the best mode of analysis then in use, is much too high. It was probably a mixture of oxygen and nitrogen. Later analyses, conducted on more refined principles by Richardson, give an average of nitrogen and oxygen, of 8.852 in caking, splent, cherry and cannel coal. What proportion these bear to each other, does not appear; but, since Liebig, deducing the composition of coal from woody fibre, by subtracting water, carbonic acid, and carburetted hydrogen, *excludes nitrogen from coal*, we may suppose that it does not

amount to a much greater proportion than that actually formed by Dr. Schafhaeutl, in Welsh anthracite. The average of two samples affording of nitrogen only 0.962, or, in round numbers, one per cent. This analysis confirms what observation has long shown, that this burning of our anthracites, produces abundant ammoniacal salts. The remark of J. E. T., therefore, that anthracite contains no nitrogen, requires modification. Had not analysis detected nitrogen, we might have attributed (as no doubt it is, in part,) the formation of ammonia in this case, to the passage of moist air over the ignited carbon; a well known and abundant source of the formation of this alkali. It is a question whether the spontaneous decay of coal ever evolves ammonia. It is on this point that the explanation of J. E. T. rests, so far as bituminous substances forms part of Daniel's manure. Spontaneous decay is a very different process from dry distillation in a closed vessel. It is quite probable that the bitumen acts less than the sulphur. This last acts by gradually forming sulphates, and probably your correspondent is right in attributing very little to its effects. We have then, sawdust, alkali and lime for the active agents. The effects of the new manure are due to other causes: 1st. To the evolution of carbonic acid gas. 2d. To the alkali forming soluble geine, with the woody fibre, whose decay is hastened by the presence both of that alkali and of lime. The sawdust, containing all the elements of manure, organic and inorganic. Dry sawdust exposed to air, decays—carbonic acid, water and ammonia result. While it loses, thus 3 parts in 100 of carbon, it loses 12 parts of oxygen and hydrogen, as water; or loses altogether 15 parts. If the air is excluded, as in the present case, and moisture is present, then the water is decomposed and a larger portion of carbonic acid is formed. The loss of weight is now from 18 to 25 per cent, and the resulting mass is geine or humus. This immediately combines with the alkali and abundance of soluble manure is formed. The small portion of fixed alkali here acts like ammonia in cow dung. The immediate effects of the "new manure" are due to the evolution of carbonic acid among the silicates of the soil. These are decomposed by it. Their alkali is lost, and acts on insoluble geine in the soil; the phosphates, combined with the silicates, are set free. This action of carbonic acid upon silicates, has been quite overlooked. The necessity of forming it, among the silicates, where plants are sprouting and growing, is of the first importance. The function of carbonic acid is here of the highest order in vegetable growth and culture. It is the high function of fermenting manure. It must never be lost sight of. No matter how rich a soil may be, in geine, it that has lost the power of spontaneously and readily producing carbonic acid, it is dead, barren—it must produce carbonic acid, not for the food of the plants, but to *decompose the silicates*. On this turns the theory of rotation of crops. I shall touch upon this hereafter. To the causes above referred, is to be attributed the effect of the new manure. I doubt not the same results would follow from alkali and sawdust only—the same results which follow from muck and alkali, a little quickened perhaps, by a more free production of carbonic acid. If so, we are taught an important and practical lesson. Saw dust, or fine woody fibre, is to be added to swamp muck and alkali. All this is to be learned by trial. Let it be tried.

In connection with this subject, this evolution of carbonic acid, I would suggest to J. E. T. whether his remark, that fat is useless among the offal of the slaughter house, may not lead to a waste of a very good manure.

Fat, &c., is useful in two ways: 1st. By exposure to air, it evolves much carbonic acid. 2d. During

this process, it gives up its glycerine. This last is an organic product, highly soluble in water. To this fact, "spent ley" owes no small part of its good effects. S. L. D.

Lowell, July, 1842.

Notice.

Professor Liebig has a new work in the press on Organic Chemistry and Physiology. It will be published simultaneously in this country under the care of Professor Webster, the able editor of Liebig's former work. The work has been translated by Professor Gregory, who expresses himself as follows in relation to it.

"In my opinion, this work will mark the commencement of a new era in physiology. In translating it, I have experienced the highest admiration of the profound sagacity which has enabled Liebig to erect so very beautiful a structure on the foundation of facts, which others had allowed to remain for so long utterly useless, and of the logical structure and extreme cogency of his arguments. There is hardly a point in physiology accessible to chemistry (I mean, of course, those on which experiments have been actually made) on which he has not, by the mere force of his intellect, thrown the brightest light. In short, we now feel that physiology has entered on the true path, and the results, before long, will, I prophesy, be altogether astonishing."

On the use of Salt for destroying Grubs.

We have much pleasure in submitting the subjoined communication to our readers. Its suggestions in regard to agricultural experiments are of the highest importance. Experience is the certain road to useful knowledge. Every farmer can afford to make experiments, if not on a large yet on a small scale; and experiments on a small scale may be equally conclusive and satisfactory as others. All that is wanted in these cases is exactness of observation in regard to all the circumstances under which the experiment is made its progress thought and its results. Every practical farmer is continually making experiments. His whole course of cultivation is to a degree, a course of experiments; here then let him carefully write its progress, its incidents and its results; and let him journalise them for his own benefit, and communicate them for the benefit of his neighbors.

The "Plough Boy" we have never seen. It is we believe the only agricultural publication of the State that we are not in possession of. We wish some friend would put us in the way of obtaining a copy; and we should certainly republish the communication referred to. Nor do we recollect Cartwright's communication on preventing the rust in wheat. To the concluding suggestion of our respected friend we must demur, as believing it wholly impracticable. At a convenient season we design to treat the whole subject of salt as a manure, a subject on which much has been written but little is determined. Eo.

MR. HENRY CULMAN:—In your June number is a valuable communication relative to the efficacy of salt in destroying the grub. By way of confirming this information would it not be well to republish a communication made by Major Smith of Albany, upon this subject to the *Plough Boy*, as long ago as 1821. You will find it in the 2nd vol. 98th page.—I am induced to make this suggestion in consequence of our mutual friend H. D. Grove remarking to me that he had used the quantity per acre recommended by your correspondent, without complete success, if with any success at all—which according to Mr. Smith is quite impossible unless the salt is dissolved. My experience confirms the truth of Mr. Smith's statements—I have long since called the attention of the Cultivator to it as one of the most important communications that have been made to the farmers.

Dr. Harris, in his report on the insects of Massachusetts, has made mention of the value of salt water in removing those aphides that prey upon the roots of

plants—which confirms as far as it goes, the statement of Mr. Smith. The English periodicals contain numerous communications relative to the value of salt in destroying slugs, (snails?) and worms.—Grub worms I presume is meant. They also state that to insure success the weather and the land must be damp. Mr. Field (Cultivator, vol. 4, p 183) killed grubs by using beet brine.

Any farmer who has a quantity of old brine and a watering can may easily prove the truth or falsehood of these positions when the grubs appear next year.—It is very desirable that intelligent farmers would on some scale or other, no matter how small, settle the question experimentally—and forward the result to some agricultural journal so that from the number and variety of the communications something like certainty may be derived. It is to be regretted that the attention of intelligent farmers is not sufficiently concentrated upon the various topics of agricultural inquiry that are continual recurring. From the want of concert among them many a valuable suggestion is lost. Here is a communication from a most respectable and accurate man that has slumbered for twenty years, which would have been of incalculable value to the farmers if ten of them had during that long period stated its truth and published their experiments. It is true that with the generality of farmers their experiments are rather the result of accident than design; at least this has been the case. But as there is now a spirit of liberal inquiry aroused in the farming mind, can it not be directed in a good degree to the same channel by the agency of the agricultural editor? Will it not do for you to urge your correspondents, for example to put a good deal of salt, at once, as well as common, in their communications for some time to come, and thus furnish abundant data for settling the value of salt to the farmer both as a manure and a verminuge.

Every year the wheat districts suffer to a greater or less extent from the ravages of rust, and yet it is rendered more than probable that the free use of salt as a manure prevents this terrible disaster. At all events the celebrated Dr. Cartwright ascertained that if one pint of salt be dissolved in eight pints of water and applied to rusted wheat at the rate of two hogheads to the acre, the rust entirely disappears in two or three days, leaving only a slight discoloration of the straw. Now will not the sowing of very fine salt upon rusted wheat when it is wet with dew or rain answer every purpose and save the farmer from heavy loss?

Yours most truly, J. B. NOTT.

Norman Vale, Guilderland, July 7, 1842.

Every thing connected with the great staple of Western New York is important, and therefore we subjoin the following communication published in the Maine Farmer of a late date. We do not feel authorized to decide upon its soundness, but submit it to the observing and experienced.

Advantages and Disadvantages of the Bald and Bearded varieties of Wheat.

Mr. HOLMES:—As the farmers of Maine are at some loss as to which is the most profitable to raise, the bearded or bald varieties of wheat, I have thought that it would be beneficial to state the advantages and disadvantages of both, according to my experience.

Advantages of Bald Wheat.—The flour is whiter, takes more pounds of flour to the bushel, as the hull is thinner and there is less bran, packs closer in the bundle, and takes less room in the stack or barn. The disadvantages are, the liability to lodge or to be thrown down by storms and rains, rusts or blaste easier, or more likely to be rusted and blasted, takes longer to grow, does not ripen so early in the season, and must be mixed thinner in the paste before baking. The bread rises sooner after baking.

The advantages of Bearded Wheat, especially the Payson Williams Black Sea, are, stiffer straw, not liable to be beat down by storms or to lodge on rich land, quick in its growth, ripens early, and will do to sow late, is seldom known to rust or blaste, and prob-

ably bears more heads to the acre, though that is doubtful. It need not be mixed so thin in the paste before baking. The disadvantages are, yellow flour, thicker hull and consequently more bran. Does not make as many pounds of flour to the bushel.

Let it be remembered that all bold wheat makes white flour, all bearded wheat yellow flour.

Winthrop, May, 1842.

E. W.

Seed Wheat.—Caution to Farmers.

The subjoined is a very important communication. Some years since, having taken great pains to get some celebrated wheat from a distinguished cultivator, we received a few bushels very much mixed with rye, oats, &c. We undertook to clean it by picking out with the hand all the "foul stuff." The undertaking was most tedious; and being obliged to leave home before it was finished, we left it in charge to a man in our employ. He being very impatient, and not destitute of that self-conceit of superior sagacity so common in such cases, immediately after we left, took the whole to the mill and passed it through the smut machine. The consequence was, its germinating power was destroyed, and with the exception of a very few straggling plants, we lost our seed and our labor; to say nothing about our temper.—Ed.

Mr. COLMAN.—Through the medium of your paper I wish to caution the farmers of Western New York, against sowing wheat threshed with a machine, for I believe it is one great reason, if not the only one, why we do not have wheat grow as thick now as it did before machines came in use. I came to that conclusion last fall, and threshed my seed with flail, and the result is, my wheat came up twice as thick as my neighbors, according to the quantity of seed sown per acre, threshed with machine, which was about one bushel and three fourths per acre, and it stands so yet. I further believe wheat should be sown as soon as the last week in August, for as far as my knowledge extends, wheat sown at that time has not failed to be of a good quality, when that sowed ten or twelve days later has been very much injured by the rust.

JO. WICKOFF.

Romulus, July, 1842.

For the New Geneva Farmer, Turnips without Cost.

In well manured ground, now occupied with corn and potatoes, where it is not intended to plough the ground before late in autumn, a crop of White Norfolk or other fast growing turnips, may be raised without detriment to the present crop, and without any cost excepting the seed and sowing, by scattering a small quantity between the rows the last time the cultivator or plough is passed between them. This latter operation every good farmer knows, should be done much later than many practise, stirring the soil and destroying the weeds often being a matter of great importance, so far at least as the corn crop is concerned, even when the plants have attained the height of two or three feet. The corn being cut up early in autumn, leaves the full occupancy of the ground to the turnips and they advance rapidly in growth. When sown among potatoes, they will in general have at least one month for growth after the potatoes are dug from the ground.

It is true that by this method heavy crops cannot be obtained; but that a considerable quantity is generally afforded and much more cheaply than they are otherwise obtained, has been sufficiently proved by the experience of the writer.

J.

Lime and Mode of Application, from Proceedings of Royal Agricultural Society in June last.

Mr. Raymond Barker communicated some observations on the use and abuse of lime as a dressing for land, by Mr. Wm. Henry Fisher, at 15 Conduit street, London. The author's great object is to impress upon farmers the importance of using quick lime, and not lime which once had been quick, but

by delay in use and exposure to the atmosphere has become effete, and has absorbed from the air the carbonic acid which it again changes to the carbonate of lime it was before burning. He considers that many thousands of pounds are annually thrown away by agriculturists from want of a proper knowledge of this simple fact; and he recommends them to use their lime in the fresh burnt state, by carting it direct from the kiln upon their land, spreading it in the lump, and in that state ploughing it in directly, the sooner it being got from the kiln into the land the better. The author concludes his communication with the following remarks:—"The lime will be found, if properly burnt, on a second ploughing, to be crumbled to pieces or powder, and on harrowing will be intimately mixed with the soil. From the heat evolved during the slacking of the lime underground, and its causticity, which diffuses itself by the agency of the moisture it meets with through the soil, it will be found to destroy, or at any rate to be extremely obnoxious to wireworms, slugs, grubs, and other enemies which the farmer has to contend with, and which are very frequently the cause of failure in his crops, as well as in rendering most vegetable matter in the soil soluble, and food for future crops. These are the properties that lime has in common with chalk; the latter, no doubt, is a very useful addition to many soils, but do not go to the great expense of buying or burning lime, and then allow it to be converted again into chalk, or carbonate of lime, before you plough it into your land. In some districts the limestone is burnt in large lumps, particularly where wood is employed as a fuel—in which case it should be broken to about the size of a small penny roll before it is ploughed in. In some cases it may be said, that, owing to the distance of procuring lime, enough cannot be brought at one time for a ploughing; all I can say is, plough it in as soon as possible. If the turnip-fly is generated in the lime, applied in the manner I have directed, would no doubt do much towards their extermination; and the same effect and result would hold good in respect to the black caterpillar. In conclusion, the good effects of applying lime in the manner recommended, I have myself experienced, and have received ample testimony to the like purport from extensive agriculturists, who, at my suggestion have adopted the plan."

Royal Agricultural Society.—Marling with Shale.

Charles Charnock, Esq., of Halfmead House, near Ferry Bridge, in Yorkshire, Eng., communicated to the Council the results of his application of Burnt Blue Shale, as a substitute for clay or marl on the billy and thin soil of his farm. Mr. Charnock stated that in the coal districts, a blue clay was brought up, and accumulated to rapidly near the mouth of the pits, as to become a great and inconvenient incumbrance to the owners; that this clay was similar to the "Blue Shale" of the West Riding of Yorkshire, and was frequently burnt, and when drilled along with crushed bones, was in this state found useful in promoting the growth of turnips; but as the whole of the heated mass required frequently to be turned over before it could be thoroughly burnt, the operation was found to be tedious and expensive.

Mr. Charnock having had some years' experience of the utility attending the application of the Blue Shale to the gravelly part of his own farm, was induced, from the success which had attended his trials of it, to select from the numerous experiments he had made on this point, one average experiment to be submitted to the consideration of the Society, and to show to its members that even an article as abundant and useless as this shale became of value if rightly applied to its proper purpose, and, as in this instance, to soils of a gravelly and sandy nature.

Mr. Charnock's experiment in question was tried upon a soil lying upon the magnesian limestone—a substratum proverbial for its natural poverty and inability to resist drought; and he enters into a detailed statement of all the particulars relating to his operations. The result of this experiment was found to be in favor of the system he had pursued; and that his barley crop gave an increase of 27 3/4 bushels, and his wheat crop 17 1/2 bushels, per acre, besides saving the expense of from 12 to 16 pounds of rape-dust on the crop.

Waterloo Woollen Factory.—Is now daily thronged with farmers and farmers wives, many of the latter encumbered with their nurslings; 4000 lbs. of wool, on the daily average in June, are here sold or exchanged for cloth—the long sales room is crowded with eager buyers; such another hum of voices and confusion of tongues, is not to be found outside a Jews Synagogue.

S. W.

TRANSACTIONS OF THE NEW YORK STATE AGRICULTURAL SOCIETY.

The Report of the Jefferson County Agricultural Society is exceedingly well drawn up. We give merely an analysis or abridgement of its contents.

The report commends the practice of manuring fallows for wheat. It would have been gratifying and instructive, had the committee informed us when and how this manure was applied; whether at the first ploughing or at the last; what manure is applied and in what condition; whether ploughed in or dragged in; and in what quantities.

The average yield of cheese to a cow, 309 pounds, by which we suppose is intended new milk cheese only, is respectable, but not more than that, in a country where the pasturage is so abundant. The yield of butter, 112 pounds to a cow, is much less than it should be. In Cheshire, Mass., 500 lbs. of new milk cheese and 25 lbs. of butter are not infrequently obtained to a cow, in dairies consisting of thirty and forty cows, and we have known, of butter, 180 lbs., 200 lbs., 212 lbs. obtained to a cow, where several cows have been kept. We speak in this case of native stock altogether; what might be done with the Improved Stock and with better keeping, remains to be seen.

Premiums appear to have been bestowed upon three farms, although ten farms are briefly referred to. The names of the successful competitors in these cases do not appear, and in only one case is the town referred to in which the farm is situated. This is a singular omission, for which undoubtedly the committee had their reasons, but do not give them. No 5 particularly, is represented by the committee as being "as fine a farm, in all respects, as the county affords. There are on it 750 rods cedar post and board fence and 350 rods staked with perpendicular stakes." Now it must be admitted that this is a very meagre account, and about as instructive as if the committee had told us of a farm in the moon of as many acres and with just as many rods of stone wall.

We like very much the suggestion of the committee to give a premium to the best farm in each town; and we mean no disrespect in remarking upon the deficiencies of their valuable report; but the object of agricultural premiums is not merely to stimulate agricultural skill, industry, and enterprise; but also, and chiefly, to obtain from another man's success such information of his mode of operation as may enable us to obtain similar results. From a farmer, who becomes the subject of a premium, we should have so extended an account of his whole farm management, operations and experiments, that his farm may serve as a pattern and guide for others. But where not only the farm management is not detailed, but even the names of the farmers and the places are not given, certainly the public are little benefited; and one of the best objects of giving premiums is entirely defeated.—Ed.

Jefferson County Agricultural Society.

Paid in premiums, \$385 00.

The viewing committee visited twelve towns of the county, and inspected twenty-two farms and eighteen dairies. It is the unanimous opinion of the committee, that the premium should hereafter be given for the best farm in each town.

Desirable Improvement.—We distinguish a most gratifying improvement throughout the county. The committee regret that less attention is paid to ornamenting the front yards of the new houses with shade trees and shrubbery, than they deserve. Attention paid to these interesting objects, is labor well applied.

Fallows Manned.—We observed a great deal of land sowing to wheat. We never saw fallows in finer condition. Among the gratifying improvements every where observable in our husbandry, the renewed attention now paid to manuring the fallows is very conspicuous. In the first settlement of the county, good crops

were raised without manure; but the generality of our lands demand it. Diligent attention paid to accumulating heaps of compost for our fallows, can alone ensure us a reasonable prospect of a profitable crop. Whether lime can not be used to as great advantage, as in some of the older States remains to be seen. To our knowledge the experiment has not, as yet, been clearly tried.

Apple Orchards.—We saw enough to convince us, that with proper attention, the common prejudice that apple trees will not flourish well north of the Black river is erroneous. We passed some as fine orchards in this section, as are to be found in any other parts of the country.

Fencing.—Great improvement has taken place in fencing. Some farms that we visited are almost wholly fenced with straight post and board fence, thus making a great saving of land, as well as a permanent and handsome barrier.

Public Roads.—We found the roads perfectly good; though much of this is owing doubtless to the dry season, yet in turnpiking and bridges there is a gradual improvement. In the town of Alexandria, the newest in the county, we found the roads fully equal to those in the oldest town.

Canada Thistle.—We saw less of that pest to our farms, the Canada thistle, than has heretofore been observed. Our good farmers have learned to exterminate them by thorough ploughing and mowing. It is the duty of the path-master to have these cut from the roads, but surely no good farmer would allow them to remain on roads passing through his farm, even should the overseer neglect his duty, which is manifestly the case in some places.

Size of Farms.—One great error in our farming, observed by us as well as others, is in having too large farms. Except for grazing, it is questionable whether a farm ought to exceed one hundred acres; and one half of this may be considered ample for a farmer who has not a family of boys to assist him. It is a fact often spoken of in the older portions of the State, that after the paternal farm has been divided among the children, as much is raised from the parts by increased attention to manuring and cropping, as was formerly raised from the whole. It is very certain that a small farm adjoining the village of Watertown, of about forty acres, is, by thorough culture and undivided attention to that small number of acres, made more profitable to its owner, Hart Massey, Esq., than some farms in the county of three times the size.

Silk Culture.—The raising of silk worms and the manufacture of silk, is, as we learn, in very successful operation in Carthage. The small children of the family can be employed in this occupation to great profit.

Cheese Dairies.—The twelve cheese dairies we visited milked in all three hundred and fifty-four cows. By adding to the gross amount already made one third for the remainder of the season, we find that each cow will have made 309 pounds of cheese. At six cents per pound this brings the earnings of each cow to eighteen dollars and fifty-four cents for the year.

Butter Dairies.—The six butter dairies offered to our inspection milked one hundred and eight cows; adding one third to the amount now made, they will average one hundred and twelve pounds each; this, at fourteen cents per pound, is equal to fifteen dollars and sixty cents; a difference in favor of the cheese dairies of two dollars and eighty-six cents each cow.

Premium Farms.—The farm to which the first premium is given, contains about one hundred acres of improved land. The present occupant has been on it thirty-three years; he originally took up but forty acres, and having paid for that, has been gradually adding to it. It is a grazing farm, and in a high state of cultivation, not a weed or a thistle to be seen upon it!!

There is on this farm, 550 rods of cedar posts and board fence.

The second premium has been given to a farm of 160 acres, 80 of which are improved. The owner has on it, 700 rods of handsome stone wall, nearly every rod of which was laid by himself. It has a fine orchard, and is in all respects in the most favorable condition.

The third premium is awarded to a farm in the town of Alexandria. This farm is an example of what can be accomplished in a few years of patient industry. It contains 200 acres, of which 150 are improved. It is mostly a grain farm, in a high state of cultivation, free of weeds and thistles, and has been cleared by the present occupant within the last nine years. There are on it 1000 rods of black-ash fence.

Onondaga Agricultural Society.

This is a highly valuable report, and may be read with advantage by every farmer. Mr. Gaylord's notion that by keeping the locust tree shaded he shall avoid the attack of the borer, remains to be proved. We should be glad to know on what facts or experience it rests. The most successful experiment, we have known, in expelling and keeping off the borer has been made by Allen G. Metcalf of Lenox, Massachusetts. He washed his locust trees as thoroughly as he could with spirits of turpentine mixed with water. His trees were much infested with the borer. After this they were not found, and when we saw the trees, which was some years after the application, they had not returned.

Mr. Gaylord's corn it appears was much injured by the wire worm. We have known one good farmer, who was accustomed, after ploughing green sward, to take a crop of oats, that he might avoid the wire worm, as his corn always suffered severely when it was made the first crop in such cases. Another experienced farmer recommends not ploughing until very late, so that there may be a considerable amount of young grass turned under, upon which the worms might feed, instead of feeding upon the corn.

We gave an account in a late paper of a skillful farmer, who was accustomed to mix salt with his manure, by which he, from long experience, was satisfied that his corn was saved from the attack of the worm. From this and some other facts known to us, it seems quite desirable that salt should in some way be tried for this object. It is important that it should not be applied in too large doses.—Remember Lot's wife, poor woman! —Ed.

Onondaga Agricultural Society.

The farm of Silas Gaylord is on the west bank of Skaneateles lake, and about four miles south of the village. This farm contains 145 acres, 25 of which are covered with wood. The 120 acres are all arable land, and suitably divided into fields, on which is pursued a course of crops. A large share of the western part of this farm was formerly so wet as to be unfit for tillage. This Mr. Gaylord has very properly reclaimed by underdraining, which is a very profitable operation on lands which are so moist as to be otherwise untillable. Twelve hundred rods of stone underdrain are already constructed on this farm. The buildings are well located and in good repair. The outbuildings are extensive and convenient, especially the barn, which is very large, with cellar, shed or stabling, under the whole of it. This is a great improvement, as it requires no additional roof, and furnishes a place where stock can be kept comfortable in the most inclement weather; a convenient cellar for the preservation of roots, and a place for preserving manure from the great waste attendant on exposing it to the storms of winter and spring.

The farming tools are in good order, under cover and ready for use. The fences mostly in good order, and

a large share made of posts and boards. The fields are generally in good order, and few weeds are allowed to perfect their seeds. All vacancies in the timber land are filled by transplanting locust trees, which are taken from a nursery on the farm. By thus keeping the locust tree shaded, Mr. Gaylord thinks he shall avoid the depredations of the borer. The stock on this farm consists of 33 neat cattle, all of which are full blood or grade Durham, 4 horses, 15 hogs, and 74 sheep, of the improved English varieties. The division of the farm the present year, with the quantity of crops is as follows:

Wheat,	18 acres,	400 bushels.
Barley,	10 do	300 do
Peas,	5 do	100 do
Oats,	5 do	200 do
Potatoes,	2 do	320 do
Corn,	3 acres,	much injured by wire worm.
Meadow,	30 acres,	60 tons.
Pasture,	45 do	

The farm of Mr. Gaylord exhibits the practical good sense and untiring industry of its owner, and is well worthy of a visit from those who are designing to raise stock, or erect the out buildings which are necessary on a stock farm.

Your committee were next called to view the farm of Fletcher Woodward, situated on the turnpike, five and a half miles west of Syracuse. This farm contains 236 acres, 225 of which are under improvement; all tillable, and in a high state of cultivation. This farm is naturally adapted to the raising of grain, and to this Mr. Woodward gives most attention. The course of crops which is produced is: 1st, corn or potatoes, on a clover ley, then oats or barley, which are followed by wheat, after one and sometimes two ploughings; then sows eight quarts of clover seed, two quarts of timothy seed, and three to four bushels of plaster per acre on the wheat, after one in the spring, and pastures one year after the wheat is harvested. Mr. Woodward sows from one and a fourth to two bushels of wheat per acre, according to the time of sowing; prefers sowing from 10th to 15th September. Never sows grass seed with any crop but wheat; general average of wheat crop per acre, from 20 to 27 bushels; has raised 48 bushels per acre on small pieces. Corn is invariably raised on green sward, with one ploughing, harrowed down smooth, and struck out both ways; rows north and south, 3 feet 4 inches east and west, 2 feet 8 inches apart. Plants early in May, with plenty of seed, coated with tar, and thins at hoeing to 4 stalks in hill; plasters as soon as up, and again after second hoeing; uses the cultivator, hoes 3 times, and makes very little hill.

Barley is generally sown on pasture land with one ploughing; general crop 30 to 58 bushels per acre; sows from 2 to 2 1-2 bushel per acre; oats are cultivated after corn; sows 2 1-2 to 3 bushels per acre; general crop 50 to 80 bushels per acre.

Mr. Woodward's method of cultivating potatoes is to draw at the time of threshing wheat, (with a pair of horses and rope,) the straw, and deposit it in large bunches on a clover ley, leaving a narrow strip all around the field, on which no straw is put. In the spring this narrow strip is ploughed and harrowed fine; then drops the seed once in two feet each way; covers about one inch deep, and keeps the surface as near level as possible. He then takes the straw adjoining this circle, around the field, and deposits it evenly on the ground already planted, to the depth of about 4 inches, when settled together. This leaves another strip for ploughing, which is treated in the same manner as the first, and so on, until the crop is ready to harvest, which is usually from 300 to 500 bushels per acre. This farm is divided into fields of the average size of 23 acres. The fence consists of 963 rods of posts and boards, 215 rods of full wall, and 180 rods of half wall, all in

good order. For the convenience of passing these fences, 33 gates are already hung, and the committee were informed by Mr. Woodward that he had contracted for 22 additional gates to be erected this fall. The quantity of produce raised on this farm the present season is as follows:

Wheat,	88 acres,	1760 bushels.
Corn,	20 do	1460 do
Oats,	33 do	1320 do. injured by drought.
Barley,	25 do	750 bushels.
Potatoes,	5 do	1500 do
Meadow,	10 do	20 tons.
Pasture,	47 do	

The stock kept on the farm consists of 12 horses, 28 neat cattle, 83 hogs, and 150 sheep.

Mr. Woodward has given a practical illustration of the fallacy of the idea which is so often advanced, that the farmer cannot afford to be nice in his farming operations, and that the profits will not pay for an outlay of extra capital in improving the soil and fence. One of the committee asked Mr. Woodward if he took an agricultural paper, to which he replied—"I do, and have for a number of years, and have found it of great use. And could I have had the Cultivator, with the present light upon the subject of farming, when I first commenced, (18 years since,) I think it would have been more than \$1000 benefit to me."

The farm of Mr. Woodward exhibits in a favorable manner the beneficial effects of what is denominated the new system of husbandry. The antiquated customs of farming which our forefathers followed, are not so dear to him as to cause him to shut his eyes to the improvements which modern agriculturists are annually making in the science of farming. He is not so fearful of being called a "book farmer" as to refuse to take and read the agricultural publications of the day. He is not so fearful of being denominated a theorist as to refuse to try the improvements which are recommended in those publications; and his farm shows the consequence; it being well fenced, well cultivated, very productive, and very clear from weeds, none of which are suffered to seed. In short, everything shows that the operations on this farm are directed by an enterprising, intelligent, practical farmer.

Your committee were next called to examine the farm of Hiram Church, situated in the town of De Witt, 2 1-2 miles northeasterly from Syracuse.

This farm contains 137 acres, about 100 of which are under improvement, and all suitable for tillage. It is divided by a good cedar fence into fields containing about, 10 or 12 acres each. The produce of this farm the present year is,

30 acres wheat,	673 bushels.
4 do corn,	200 do
6 do oats,	360 do
3 do peas,	75 do
1 acre potatoes,	150 bushels.
12 acres meadow,	24 tons hay.
22 do pasture.	
22 do summer fallow.	

Mr. Church prepares his ground for wheat mostly by summer fallowing, ploughing three times. His method of raising corn is much like that pursued by Mr. Woodward, except Mr. Church uses a small plough instead of a cultivator; consequently he makes some hill around the corn.

The stock kept on this farm consists of 9 neat cattle, 7 horses, 10 hogs, 60 sheep. Mr. Church makes liberal use of clover seed and plaster, and this practice your committee would earnestly recommend to every farmer.

The farm of Mr. Church is newly improved, compared with the farms of Mr. Gaylord and Mr. Woodward; but is naturally choice grain land; and we doubt not, with the industry and enterprise which Mr. Church exhibits, it will soon show such a degree of

neatness, and amount of produce as few, if any, farms can now exhibit.

Royal White, of Onondaga, called the attention of the committee to a field of wheat, containing four acres and fifty-two rods, which Mr. White informed us yielded 167 bushels of wheat. Method of cultivation—broke up about the middle of June, about ten inches deep, and immediately harrowed. Ploughed and harrowed again the fore part of August. Ploughed and harrowed the third time the 10th of September, and immediately sowed with seven bushels of Canada flint and white flint wheat. Three-fourths of an acre of this piece of land was sowed with peas, and was ploughed but twice.

Col. W. Abbott, of Otisco, presented a fine sample of spring wheat, which he originated by a series of experiments from the bald flint, which is a well known variety of winter wheat. For an account of his experiments we would refer to page 133, of volume 9 of the old Genesee Farmer.

The committee recommend that the first premium on farms be given to Fletcher Woodward. The second to Silas Gaylord, and the third to Hiram Church.

It was unquestionably the intention of the Legislature, when they passed the act for the promotion of agriculture, and devoted a part of the funds of the State to that object, that the money so distributed, should be applied in the way best calculated to benefit the agriculture of the State. To do this, it was not deemed enough that agricultural fairs should be held, and the money expended in premiums, but provision was expressly made for giving the greatest publicity to the modes of agriculture adopted, or the different processes pursued, by the successful applicants for premiums. No premium was to be awarded, until the statements referred to, had been made, as without the knowledge that could be gained in this way, one half of the advantages to agriculture, proposed by the State in its appropriation of funds, would be wholly lost. All such statements, reports, vouchers, &c., made to the several county societies, were to be transmitted to the Executive Committee of the State Agricultural Society, whose duty it would be to select, compare, condense, and arrange into a report to the Secretary of State, such papers, statements, &c., as should be deemed best adapted to subserve the cause of agriculture in the State. The Executive Committee regret to say, that in too many instances, these requisitions of the law appear to have been entirely overlooked; and that where partial returns have been attempted, they have in most cases, been very meagre and unsatisfactory, barely an approximation to the returns contemplated by the provisions of the act."

Sowing Plaster.—Many farmers suppose that plaster should only be sown after spring vegetation has advanced; this is evidently a mistake, as plaster must be dissolved before its manuring properties are developed; rain, frost, and even snow, are necessary to effect this result; hence some have observed that their plaster did no good in a dry season of the first year. S. W.

What shall Farmers do, when Doctors disagree?—It has been said that plaster thrown among horse litter will seize upon the ammonia of the urine and preserve it with the manure. I believe this is agreeable to Leibig's theory; but other chemists say that the lime in the plaster will certainly expel the ammonia. S. W.

Fall Ploughing.—Some farmers condemn fall ploughing, because it does not succeed on an easy-riable soil. Is this any reason why a stiff clay should not be improved by it? A clay garden with long manure ploughed under in the fall, will save much tedious labor in the spring, besides vegetation will be much earlier. S. W.

ROCHESTER, AUGUST, 1842.

AGRICULTURAL EXCURSION.

By the invitation of several respected friends in Monroe and Livingston County, the editor has had the pleasure of passing a few days with some of the excellent farmers of the Genesee Valley. He gratefully acknowledges their kindness and hospitality. He could not have had a more delightful excursion. He is never more at home than among the farmers, and truly enviable is the condition of the residents of this charming country. He has taken the liberty of adding some hasty and superficial observations made in this joint in reference to the agricultural condition of this region, which he trusts will give no offence, and which will be extended when he has more room. They are given not from any conceit of their value—very far from this; but in the hope that they will call attention to the subjects adverted to, and elicit communications from those whose intelligence and experience would greatly instruct the agricultural community.

The Genesee Valley.

The river Genesee rises among the high lands of Pennsylvania in the neighborhood of the Susquehanna. Winding its way among the mountains, it enters New York by the Southern side of Allegany county, passes into Livingston county, which it divides longitudinally nearly in the centre, and after traversing the whole breadth of Monroe county pours its rich tribute into Lake Ontario. At its ordinary level it presents an average breadth of only a few rods. Its course is remarkable for its windings and doublings. It has some rapids; and it has at least six considerable falls, all within New York, of remarkable picturesque quality; and at high water, of singular beauty and grandeur. Its rapid torrents, its brilliant cascades, its sweeping and in some cases its terrific floods, and its lofty and precipitous walls, rising for a considerable length of line to a height of 400 feet and presenting in some instances, perpendicular cliffs of 600 feet, are objects of attraction to men of taste, the geologist, and the curious traveller. In these respects they are surpassed in the Northern United States only by the world's wonder, the giant of the waters, Niagara.

The river, after successive leaps and rapids soon after leaving Allegany county, at Mount Morris becomes a quiet and in low water a sluggish stream, bordering on each side meadows and alluvions of large extent and eminent fertility. At the village of Mount Morris the river may be said to enter the Genesee Valley. Here the flats begin, forming an extensive region of alluvial meadow, surrounded by hills of medium elevation and of easy and gradual ascent, presenting an expanse of an average width of more than two miles, as nearly as the eye would enable me to judge. A large portion of this land is cleared and under cultivation. It was to a degree cleared when the whites first came into the country; and was a favorite resort of the Indians, whose judgment directed them to select the most fertile as an instinctive taste led them to spots the most picturesque and beautiful. A considerable portion is still occupied by a deep and dense forest of extraordinary magnificence: The parts which are cleared, are adorned, or perhaps it might be properly said, left with excellent taste, as they were adorned in their original condition, with here

and there a single tree of beautiful proportions, sometimes a bolt of considerable length, and at other times a clump equally as graceful in their shade as they are exquisite in their form and foliage. The largest tree that has ever come under my observation, is an oak on the meadow of Mr. Wadsworth in Genesee, being full eight feet in diameter, standing out in its majesty as the contemporary of other generations and the mute historian of departed centuries. Under its shade the imagination naturally reverted to days gone by and to the changes which have transpired during its long reign. The wild children of the forest, who were accustomed to gather under its spreading branches to celebrate their rude festivities or hold their councils of war, have all departed; and the quiet and rejoicing herds, marking the progress of civilization and humanity, repose securely around it. The council fires are extinguished; the deadly arrow no longer rustles among its boughs; and the warwhoop and shrieks of vengeance, which once filled those valleys with terror, have given place to the songs of harvest-home and the gentle and peaceful undulations of the village bell. Everywhere among these meadows, clad in a verdure of surpassing depth and richness, and waving with their golden harvests, cultivation has triumphed over the rudeness of nature, and art and skill and taste display their brilliant trophies.

It was once asked what was the use of rivers, and the reply was, to feed canals with. Acting upon this assumption, the State has penetrated the whole of the Genesee Valley, from Rochester to Dansville, with a canal, and availed themselves of the waters of the Genesee river to fill its banks. The line of passenger boats on this avenue are of the best description. The canal from Rochester passes for some distance through an unbroken forest of extraordinary growth until presently it emerges into a highly fertile and cultivated country, and for its whole distance to Mount Morris, as far as we pursued it, intersected an agricultural country as rich as the eye could rest upon, and dotted all over with flourishing villages and the abodes of rural wealth and independence. Nothing seems wanting to render the picture perfectly enchanting but an expanse of water; and if nature had seen fit to spread out in this valley a lake like that of Canandaigua or Seneca, the imagination would have had no difficulty in recalling all the beauties and splendors of the primeval state.

THE SOIL.—The soil of the country varies somewhat in different places, but is throughout strongly aluminous and calcareous. On the meadows or flats it is alluvial and full of vegetable mould, the washings and gradual deposits of the hills, and so clayey as to be used with advantage for bricks. In some cases on the uplands, it is so strongly clayey as to be cold and heavy, and unfavorable to any grain crop and difficult and discouraging in the cultivation. The best soils are undoubtedly those of a gravelly nature; with clay enough to render them tenacious; and full at the same time of small and finely comminuted stones, which are supposed to be limestone, though as well as I could learn no exact chemical analysis has been made in any case. This kind of soil prevails in Wheatland, Caledonia, York and other places, and is eminently productive. On Mr. Wadsworth's farm in Genesee, I found a marly substance composed of lime and clay, which readily effervesced with acids, indicating the presence of carbonic acid. In the hilly portions of Mount Morris, the crops were later than in the valley region, but promised most abundantly. Here, it was stated to me, no lime is found. These lands, however, have been much more recently brought under cultivation than those which I have before adverted to. The best crop of wheat which I found in my whole journey, though by no means the most extensive, that which promised best in respect

to its evenness, cleanness and fulness, was in this part of the country on the farm of James Conklin of Mount Morris. It was of the red chaff variety. None of these soils as yet, however, exhibit any diminution of their product, though in some cases the cropping is severe and often without manure.

CROPS.—The crops cultivated in the country are almost wholly wheat, oats, and grass. Wheat every where predominates, and is the article on which the farmers mainly depend for their cash returns. On the alluvial meadows herds-grass, red top and various natural grasses prevail; on other lands, subjected oftener to the plough, clover is mainly cultivated.

Of all the crops, wheat claims the principal attention of the farmer. The average crop, as rated almost unanimously by the intelligent farmers whom I consulted, does not exceed twenty bushels, which is certainly very much below what the land is capable of producing. Where the error or deficiency lies, if error or deficiency exist, is not readily perceived; but if possible it is most desirable that it should be ascertained. The quantity per acre of seed sown is about 14 or 15 bushels, and the general practice is to wash in brine, and lime the seed before sowing. The time of sowing is from the first to the 15th September. One or two farmers spoke of the advantage of putting in their seed the last part of August.

Much larger crops are sometimes obtained, and I saw several fields of large extent, which might safely be put down at thirty bushels per acre. Mr. Sheffer near Scottsville, one of the earliest settlers in this country and the owner of a magnificent farm originally of 700 acres, in Monroe county and intersected by the canal, in the early settlement of the country obtained from forty acres of land in a single field, 2500 bushels of wheat, which was at the rate of 62½ bushels per acre. Within a few years, Mr. Hall, in the centre of Wheatland, on 12 contiguous acres of land, obtained 648 bushels, or 54 bushels per acre. A neighbor of his, Mr. Blacknir, obtained in one case 68 bushels per acre.

Not having had the pleasure of an introduction to either of these farmers, I could not ascertain what particular circumstances of soil or culture enabled them to produce crops so extraordinary. No such results are matter of accident, or, as it is often termed, luck, and must in a great degree depend on some peculiar superiority in the condition, cultivation, or management of the soil. The best cultivation in England and Scotland produces 50 and 60 bushels of wheat to the acre. Now there is no circumstance connected with our climate, soil or condition, which should prevent the wheat farmers in the Genesee valley from producing as much as can be grown by any farmer on any land in the world; and the difference between 20 and 50 and 60 bs. in the produce of a field, certainly deserves all consideration. The crops of Wm. Garbut of Wheatland, whose farm for its condition and crops, strongly attracted my attention, usually average twenty-five bushels per acre. There certainly is no reason why our friends Garbut or Harmon, two of the best farmers in the country, should allow themselves to be out done by any farmers in any country.

Mr. Harmon of Wheatland, has taken great pains in the cultivation of wheat, and made experiments with several kinds of wheat, having cultivated them separately with a view to ascertain their comparative times of ripening, their hardness, their proof against freedom from injury either by insect, rust or mildew. He is still pursuing these experiments with great care. At the Monroe Agricultural show he exhibited twelve different kinds in grain and in sheaf, with a view to attract the attention of the farmers to this important subject. He has now growing several of the bald and bearded varieties, among which are

the Talavera, the Provence, the Virginia May, the Red Chaff, the Hutchinson and the Crute, besides others; and of the comparative result he has kindly promised a full account.

He desires me likewise to say, that if farmers will apply to him for seed, they may rely upon that which is clean and genuine. I can have no doubt that this warranty may be entirely relied upon.

Oats are here a remarkable crop. I have never seen heavier crops any where. The oat usually cultivated is the common branching oat, and weighs 32 pounds per bushel and yields ordinarily forty and upwards of bushels per acre. I saw one field of the Tartarian or Horse Mane oat, so called from the panicles hanging all on one side. This I think was at the Shaker settlement in Groveland, and in their cultivation usually yielded from 40 to 60 bushels per acre. The largest growth of the common oat I saw on the rich meadows of Mr. Cuyler in Leicester; they were nearly five feet high throughout the field. Their yield, though it must be matter of conjecture, would probably not be less than 50 to 80 bushels per acre. But by far the best field of oats which came under my notice, was on the well managed farm of R. Harmon in Wheatland. It was the Scotch potato oat, weighing ordinarily 44 lbs. per bushel, and must yield a very large crop. This oat is said to degenerate after the first year's cultivation. It would be well to inquire what occasions this degeneracy.

The amount of seed sowed is $\frac{1}{2}$ bushels per acre. Mr. Harmon informed me that in one instance he obtained forty bushels from 15 qts. sown. I found some farmers who were accustomed to sow three bushels per acre. The black oat is sometimes cultivated, but I know no advantage which it has over any other.

Rye appears to be scarcely cultivated here. I saw in my journey only one field. Where as much wheat can be obtained as rye from the same extent of land and with no greater expense of cultivation, the superior value of the wheat product leaves no ground for hesitation as to which to choose.

BARLEY.—Of Barley I saw many fields and some very heavy. The average yield sited to me was 25 bushels. Wm. Garbut of Wheatland, gives me as the average product of his fields, forty bushels. He sows the double in preference to the four rowed barley, and considers one bushel of barley as food for any stock, equivalent to a bushel of corn. Some extensive fields on the Genesee flats must yield more than forty bushels to the acre. The breweries in the country formerly created a large demand for barley, but the progress of temperance has greatly abated this demand.

PEAS.—Peas are considerably cultivated, and under successful management yield forty bushels per acre. This, however, is an extraordinary yield. They are mainly cultivated for stock, the grain being quite equal to corn for sheep, and the haulm, when well saved, is as nutritious and as much relished as any long feed which can be given them. A pea called the grass pea I found growing in two instances, in the one for the use of Bees, for which purpose it was sown broadcast and much esteemed; in the other, as matter of experiment, in order to ascertain its yield and its value. It did not promise much.

INDIAN CORN.—This may be considered as a rare crop in the Genesee Valley, and the cultivation of it inferior. Mr. Wadsworth gave it as his opinion that the average yield was not over 25 bushels per acre; but Mr. Bond, an experienced and intelligent farmer, stated that with good cultivation fifty and seventy-five bushels per acre might be had, and he had himself known instances of 116 bushels per acre. Indian corn is evidently not a favorite, and is fairly distanced by its great competitor, wheat. There may, in the condition of the market and various local circumstan-

ces, be good reason for this; but when the value of the grain and the value of an acre of well cured corn fodder are both considered, when sheep, or horses, or horned cattle are kept, I believe that the corn crop deserves much more attention than it receives.

I was surprised at the statement of Mr. Brooks of Brooksgrove in Mount Morris, that corn to use his own expression will not grow there upon newly cleared land even when it has been burnt over; and that the land must be sometime under cultivation before a crop of corn can be produced. This is contrary to almost universal experience in other places, where newly cleared and burnt land is considered highly favorable to corn. I am at a loss to account for this, but I cannot defer to so high authority. Large crops of wheat are obtained here. The growth is principally oak on the high lands, with some sprinkling of hickory; on the lower and moist lands we find much rock maple and elm.

POTATOES are not largely cultivated. They are valuable for sheep; but the present prices of pork and beef give no encouragement to their cultivation for swine or cattle. That potatoes are much more valuable for sheep and cattle than ruta baga, I have no doubt; but as many bushels are not usually obtained on the same extent of land; and the care of preserving and the cost of seed, and the labor of harvesting favor strongly the cultivation of ruta baga in preference.

ESCULENT VEGETABLES.—In so hasty an excursion through the country and so superficial a view as was in my power, it would be presumptuous in me to speak with confidence on any subject connected with the husbandry of the country, or think to afford much knowledge in relation to it. I can only say that I saw but a single instance of the cultivation of esculent vegetables for stock. This was on the farm of Mr. Garbut in Wheatland, who had several acres in carrots, beets and mangel wurtzel. I must leave it to some other occasion to discuss the pros and cons in relation to this matter.

OF FLAX, I saw only one field and that at the Shaker village in Groveland. It appeared well. The habits of this industrious people, who, as a general rule and as far as it can be done, produce and manufacture all their own clothing, lend them to the cultivation of flax, which is in a great measure abandoned by other farmers. This crop I am persuaded might be cultivated to advantage by many farmers. Where 300 lbs of lint and fourteen bushels of seed can be obtained to an acre, and this is not uncommon under good cultivation, the crop will yield an ample compensation for its expense. (To be Continued.)

Crops and Markets.

Throughout the whole country the crops of wheat and grass are represented as most abundant and fine. There are some small complaints of rust in some places, as indeed there always will be, but they are of little moment; and a finer season for harvesting never was known. It has been almost unexampled.

Indian corn, likewise, which at first seemed likely to fail, is making rapid advances, and promises a good crop. The same with potatoes, barley, and all other products.

The crops of wheat in Ohio and Michigan are likewise as good as ever known. The price of wheat in Rochester can hardly be considered as settled or even fixed, as no new wheat has as yet come into the market. Some millers have expressed the opinion that it will begin at a dollar but soon go down to 75 cents.

The Beef and Pork markets at New York and Boston remain without material change. Probably a much smaller quantity of pork will be made this season than usual, and the prices for pork or for live hogs are not likely to recede from their present position.

Wools of a fine grade command only 25 cents; and in many cases only half of this is paid in cash, and the rest in cloth. The free importation of South American wool costing less than 8 cents, and the raising of wool on the Western Prairies, for which there are large preparations, must keep prices down, tariff or no tariff.

In the midst of the greatest plenty that ever fell to the lot of any country, we are crying our eyes out for distress; and the National cow, with a swimming pail of milk under her, seems determined to kick it all over.

Prospect of prices of western agricultural products.

—As over-production and a reduction of the currency have reduced the price of most manufactured commodities, and steam is now employed on the prairies to drive the plough, it would be very strange if agricultural products (pork excepted) did not also decline in price. The cash received for a bushel of wheat, will now purchase in this village, 10 lbs. of good Rio coffee, or 20 lbs. of inferior N. O. Sugar. A pail of butter will exchange for a bundle of domestic calico and muslin, as large in bulk as the butter itself.—Ought farmers to expect this unequal exchange of commodities to continue so much in their favor always? I think not.

Flour is now selling in New York at \$6 the barrel to export to England; if Great Britain has good crops this year, and there is no failure of crop on the continent of Europe, nothing can prevent very low prices for flour in New York in one year from this time, but a failure of our own wheat crop, which is improbable, or a partial failure of our summer crops, which, from present appearances, is very possible. In either case farmers must expect and prepare themselves for small profits, as high prices from failure of crops is a calamity, which compels even the farmer to eat dear food. It is common for farmers to complain of the low price of wool, yet wool is much lower in Europe than in the United States; the English manufacturer gets fine wool from the continent for 25 cts. a pound, while our manufacturers pay our own farmers 40 cts for wool of like grade. The fact is, what is a low price to an extravagant, expensive man or family, is a high price to those whose wants are fewer, who practice a better industry, economy, and self-denial! In this reduction of profits and the consequent means of expenditure, who does not see a precious result, even to the farmer? Ask a thriving, wealthy American lord of the soil what are his troubles; if he is honest, he will tell you it is the effeminate habits and expensive wants of his children. With uninterrupted pecuniary success, where would these troubles end?

Waterloo, 8th June, 1842.

S. W.

Protective Tariff.—A farmer who writes in the May No. of the Northern Light, says that a high tariff would "make us farmers work harder to obtain the same amount of enjoyment," and "protect our industry much in the same way that it would be protected by compelling us to resume the old fashioned wooden mould board, and throw aside the cast iron plough." But the other side of the question is easily maintained in the same capital monthly—it has two sides. S. W.

Culture of Potatoes.—If they are grown in a warm dry country, as between Syracuse and Buffalo, put no stable manure in the hill; but if on cold Hemlock soil, where it rains or snows at least once a week, they may be covered in the hill with warm manure without any danger of burning up the tubers. Providence is truly kind to such countries, in giving them grass and potatoes, such as would make a western villager's cow laugh, and his own mouth water. If they can't grow good seed corn, neither can they even in their wet grounds, raise manna enough to furnish a single case of fever and ague. S. W.

On Ploughing in Green Sward for Wheat,-- Green Vegetable Manure, and the Land made to enrich itself.

MR. COLMAN--The objections of your correspondent "Turningseed," page 106, be it observed, are entirely theoretical, the result of mere opinion. Notice Agriola's remarks, page 6, for they really appear to be based upon experimental fact. Which are we to choose? I for my part have a guess, that our friend A will bring his harrow to work pretty smartly in this case, which will satisfactorily settle the question, it is need such be not already done. Probably favors his observations, inasmuch as the mellowness of the soil is at all times favorable to its fertility. The burning influence of the sun upon land deprived of its natural vegetable coating, is peculiarly impoverishing, and it seems probable that the longer this unnatural exposure is kept up, and its surface varied by repeated and rough ploughings, the greater injury it sustains by summer heats, and the more need will there be for the mellowing ingredients of manure and other dressings. If the land be rolled and dressed to receive the seed after a single ploughing, it is clear that the exposure of the whole body of the soil to the influence of the sun's rays has not been so complete as in the former instance of repeated ploughing; nothing more has been done than is requisite to destroy the former vegetation and prepare for the intended seed, which soon comes up and protects itself and the land from the parching heat by throwing out the blade that protects the root. Now it will be observed with the slightest attention, that of the three methods proposed, page 6, that by the first a good crop of clover was sacrificed to begin with, and the subsequent ploughings served to perfect its destruction, together with such weeds as might have been present, and yet with all this, plaster must be freely used; in the other two plans as before alluded to, the land was not exposed more than was requisite to destroy former vegetation.

I might add more, but leave the subject to the discussion of able individuals, and dismiss it with earnest good wishes for the success of both parties.

Yours respectfully, J. W.

Rochester, July 5, 1842.

The suggestion of our correspondent that land suffers by exposure to the sun without any vegetable covering, is very questionable and by no means an established philosophical truth. The soil undoubtedly gathers much of its fertility from exposure to heat, light and air. It suffers, however, when the vegetable matter in it is brought to the surface, and these being decayed, may be said to be evaporated instead of being retained as so much humus in the soil.

Since the remarks in our last in relation to this subject, we have visited the farm of Mr. Cornell in Henrietta, Monroe Co., who has been in the habit, for the last five years, of ploughing only once for wheat and turning in a clover ley. His success in this practice is complete, and there is probably no farmer in Western New York, whose crops yield a higher average. By this process fallows are entirely abolished; and his land is always under a crop.

We shall give in this paper an account of Mr. Keeley's experiment, to which we referred in our last, and some remarks made at a late meeting of the Royal Agricultural Society on the same subject, where, by a curious coincidence, it is advised to sow mustard with a view to its being ploughed in, in order to enrich the ground.--Ed.

On the Cultivation of Rye.--John Keeley's Statement.

To the Trustees of the Essex Agricultural Society:

GENTLEMEN--Having for some years past been more than commonly successful in raising large crops of winter rye by a process of cultivation which I believe is entirely new; I have been induced by the sug-

gestion of some gentlemen whose judgment I very much respect, to submit for your consideration a statement of the mode of culture with the produce. And that the success of the experiment this season, may not appear to be altogether accidental, it will perhaps be well to communicate the result of the process for the three or four previous years.

The land on which the experiment has been conducted is situated on the Merrimack, about a mile and a half east of Haverhill bridge; and came into possession of my father in 1827. The soil is a sand, approaching to loam as it recedes from the river. Perhaps the term *plain land* (by which it usually passes) will better convey an idea of the quality of the soil. It is altogether too light for grass. The crops we find most profitable to cultivate on it are winter rye, Indian corn, potatoes, and to some extent turnips. Oats might probably be raised to advantage, were it not that the land is completely filled with the weed commonly called charlock, which renders it entirely unfit for any spring crop, excepting such as can be hoed. The crops of rye, on the neighboring soil of the same nature, vary from seven or eight, to twelve or thirteen bushels per acre, according to the cultivation and their approximation to the river. We usually raise on the land from thirteen to thirty bushels of Indian corn per acre. Potatoes we very good in quality, but the quantity is quite small; not sufficient to be profitable, were it not that the land is very easily cultivated.

In the summer of 1827, we sowed three bushels of winter rye near the river, on about two acres of land, which produced twenty-eight bushels.

In 1828, we sowed four bushels on four acres of land running the whole extent of the plain from the river. This piece was sowed in the spring without; but they were completely smothered with charlock, and about the middle of June, the whole crop was destroyed. To prevent the second crop from coming, at the middle of August, a second crop of charlock having covered the land, it was ploughed very carefully, in order completely to bury the charlock; and then suffered to remain until the 15th of September, when we began sowing the rye in the following manner. A strip of land about twelve yards wide was ploughed very evenly to prevent deep gutters between the furrows, and the seed immediately sown upon the furrow and harrowed in. Then another strip of the same width, and so on until the whole was finished. We found the oat stubble and charlock entirely rotted, and the land appeared as if it had been well manured, though none had been applied to this part, since it had been in our possession. The rye sprung very thick and vigorously, having evidently derived great benefit from being sown and sprouted before the moisture supplied by the decaying vegetable matter in the soil had evaporated to any considerable extent. This crop produced 133 bushels.

In 1829, the charlock was suffered to grow on the land appropriated to rye, until it had attained its growth and was in full blossom. The land was then ploughed very carefully and the charlock completely covered in. In a short time a second crop appeared more vigorous than the first. This also was allowed to attain its growth, and then ploughed in as before. A third crop soon appeared, which of course was destroyed when the land was again ploughed for sowing about the middle of September. This piece of land was a parallel strip running from the river, and containing two acres. Two bushels of rye were sowed. The crop presented a remarkably promising appearance, and yielded seventy-four and a half bushels.

In 1830, the land appropriated to rye included nearly all the lighter parts of the soil, and owing to a pressure of business was not attended to as we could have wished. It was ploughed in the early part of the summer. But having intended to destroy the weeds as substituted for the second ploughing, the usual light which affected all the grain in this part of the country, led us to anticipate a small crop. It yielded however fifteen bushels to the acre.

The land on which the crop of rye was raised the present season, had for the three or four previous years been planted with Indian corn. And owing to the extent of our tillage land, we have not been able to apply more than four or five loads of manure to the acre this season. The charlock was suffered to attain its growth as usual; and on the 1st and 19th of June it was carefully ploughed in. The second crop was ploughed in on the 6th and 7th of August. On the 14th and 15th of September it was sowed in the usual manner, namely: a small strip of land was ploughed and the seed sown immediately upon the furrow and then harrowed in. Then another strip of land was ploughed, and so on until the whole was completed.

One bushel per acre was sowed as usual. The seed was originally obtained from a farmer in this vicinity, and I suppose is similar to that which is generally used. We have never prepared our seed in any manner, but have directed our attention solely to the preparation of the land; and to this we attribute our success. Owing to the unusual severity of the winter, the crop was considerably winter killed; but recovered very soon in the spring, excepting in the midfurrows. There, as the land lies very level, the water settled and so completely destroyed the rye that they continued bare the whole season. This would of course cause some diminution in the crop; perhaps a bushel or two. The rye was reaped at the usual season, and, as the weather was favorable, immediately put into the barn. The land contained one acre and thirteen rods, and yielded *forty-five bushels and three pecks. A remarkably fine sample.*

In entering a claim for your premium, I would ask your attention particularly to the process of cultivation. This, I believe, entirely new; and capable of general application.

Sowing the seed immediately after the plough, we could not have very advantageous the crop, the soil being then moist, causes the seed to spring immediately, and gives a forwardness and vigor to the plants which they ever after retain.

The process of ploughing in three crops of weeds before the seed is sown very much enriches the soil. It would be altogether unnecessary to attempt to refute the notion, that by such a process nothing more is applied to the soil, than was before derived from it. If one could not discover by the light which Chemistry has shed upon the subject of agriculture, sufficient reasons for the contrary conclusion, observation, one would think, would be sufficient to convince any intelligent man of the fact.

And here I would suggest that I do not consider the experiment as we have conducted it, quite complete. To render it more so, in the first place, in ploughing in the weeds, I would not turn a furrow after the dew had evaporated. I have no doubt but that a large portion of that fertilizing quality in the soil, which (during the summer months) is continually exhaled from the earth, is by the dew brought again within our reach, and it would be wise to avail ourselves of the opportunity of again burying it in the soil. And in the second place, I would by all means use a heavy roller after each ploughing. It would fill all the cavities left by the plough, and by pressing the soil more closely to the weeds, at once hasten their decomposition and very much retard the evaporation from the soil.

But the land is not only very much enriched by this process. There is, I conceive, no method by which it can be so effectually cleaned. Three times during the season, a fresh surface is presented to the atmosphere, and each time, as the decaying vegetable matter increases in the soil, so is the exciting cause augmented to make a more vigorous effort. We have in this manner gone over nearly all our land which is infested with charlock, and the diminution of the weeds is quite sufficient to warrant the expectation, that in a few years it may be comparatively eradicated.

Very respectfully,

JOHN KEELEY.

Haverhill, Sept 22, 1832.

The subjoined statement was made at a meeting of the Royal Agricultural Society in England on first of June last. It is not a little remarkable that this experiment of Mr. Cawston so strongly confirms the results of Mr. Keeley's experience. These cases are among the most striking on record of the value of, ploughing in green manure; and show that the means of enriching the soil at a trifling expense are within the reach of every farmer.

Vegetable Manure.

MR. W. W. Cawston, of Worlington, near Mildenhall, in Suffolk, transmitted the following result of his experience in the ploughing in of green crops--"I am not aware that the attention of the agricultural world has been drawn to the following process, which I have had many opportunities of seeing tried with the most decided and beneficial effects in this neighborhood. When trefoil has been seeded, clover or other hays failed, peas or tares grown, or a clean summer fallow made for wheat, in the middle of August, or thereabout, skeleton-plough, or plough very flat, and sow a peck of white mustard seed (*sinapis alba*) per acre; harrow in with light drag, clean off any grass or rubbish; and as soon as it is well up, top dress with a light coat of farm-yard dung (say 6 or 8 loads of 32 bushels). In 6 or 8 weeks a very heavy, fibrous, lux-

erant crop will be ready to be ploughed in for wheat as soon as the flowers are beginning to open. This operation may be easily accomplished when the plants are three or 4 feet high, by attaching a chain to the head and handle of the plough, which will completely draw it all into the furrow, and the following land surface neatly. A large supply of vegetable manure is thus cheaply obtained, and the seed costs now about 5s. 6d. per peck; while the mustard, if wanted, is excellent feed for ewes at tuppings time. If any further directions should be deemed useful, I shall at all times be most happy to supply any information I may possess."

We give with the greatest pleasure the subjoined communication, quoted from the New England Farmer of the 23d of March, first, because of its intrinsic value and interest; and next, because of the source from which it comes, Morrill Allen of Pembroke, Mass., one of the most practical, intelligent, and successful farmers in the country. We take the liberty to jog his elbow as ours is every day jogged, to remind him that the time is short, that what we do must do quickly; and that he is bound on every principle of duty and humanity to let the world have the benefit of his rich experience before he leaves it, especially as he is now taken out of the yoke. It may not seem very coming for us to catechise an old friend in this way; but we hope he will remember that five hundred miles makes no difference in the affections; the chain of friendship disdains all distance and reaches alike on pole to pole and from earth to Heaven. From the latter place, however, agricultural communications will be so direct as here, excepting in the form of dew and rain and air and ten thousand other blessed influences, but not in the way of pen and ink. This is confined to earth; do therefore let us hear from him while here, and we will listen as reverently and as attentively as if, as we have often done, we were guests at his hospitable board, or warming our feet (we cannot say smoking the pipe of friendship, that we never do but figuratively) at his kitchen fire.—*Ed.*

Leather Shavings for Manure.

MR. ERROR.—One of your correspondents inquires what is the value of a cord of leather shavings destitute of oil. We should suppose it would be difficult to find a cord of those shavings, in any manufactory, tire void of oil. There may, however, be operations exclusively in soft leather, which would produce them. We can speak only of the efficiency of the shavings in the shops of the shoemaker and currier. The use of those shavings is no doubt a powerful ingredient, but cannot be powerful enough to produce more than small portion of the effects witnessed. The gelatine skins would be generally admitted to be a very efficient manure; this quality may seem lost in the conversion of skins into leather, and there may be so firm combination of gelatine with tannin, as to defy the power of the chemist to extract from the leather anything strongly resembling the original qualities of the skin. The laboratory of nature, however, will often prove results which that of the chemist cannot. The supposed insolubility of leather shavings should not arise as an objection against the use, more than the supposition of decay against the application to land the hair and hoofs of animals, feathers and wool, which by general consent rank among the most powerful of manures.

We did not sit down to write a dissertation, but to give a narration of facts. Forty years ago, we purchased a small farm of a shoemaker, who had cast the shavings from his shop by the roadside or in the corner of his lot. Our first object was to clear away those filthy heaps. We carried them into the fields, believing if the leather could do no good, the vegetable substances would, which time had incorporated with.

Every field on which these heaps were spread, came remarkably productive;—so much so as to excite the admiration of neighbors. And something great have been ascribed to ingenuity in cultivation, which was due rather to the energy of old leather, used early, and in some degree accidental success, when we had neither read nor thought much on subjects connected with agriculture, induced us to be very sparing of scraps of old leather, we have been in the habit of cutting up old shoes and boots and spreading them on fields, and always think there is an amply remuneration for the labor bestowed. It will be

perceived there has been no course of experiment, which could qualify us to give definite answers to all the questions of "Inquirer." We think, however, that leather shavings are a good dressing for almost any description of soil; that they will assist in the growth of nearly every class of plants, perhaps more than any other material, except manure, and that their influence. We think three cords sufficient for one dressing of an acre, and believe the ultimate results of such a dressing would be greater than a dressing of six cords of the richest barn manure.

M. ALLEN.

Pembroke, March, 1842.

From the Mark Lane Express

Beneficial Effects of Bran as Manure for Turnips.

Str.—A letter appeared in the "Farmer's Magazine" of last year, giving the analysis of bran (the husk of wheat) and recommending the farmers to try it as a substitute for bones and other manures; and when tried as an experiment in competition with other manures, that the result of such experiment should be reported through some of the journals for the benefit of his brother agriculturist. With this request I am willing to comply. After losing two crops of Swedes successively in a field that had been drilled with ashes, I noticed the letters on this subject, and determined on drilling twenty-five strikes per acre of pollard, (the finer portion of bran) with the turnip seed over one-half of the field; the result proved that when the men were put in to hoe the turnips, they found the field had been sown at twice, and at an interval of two weeks; so great was the difference in the early growth—a most desirable point, as it assists their getting out of the range of the fly; this marked and sensible difference was always apparent throughout their growth, and at the maturity of the crop. There was as nearly as could be estimated an increased produce of *one-third more in weight of turnips per acre*, which must have arisen wholly from the pollard, as in all other respects the field and its treatment were alike.

The experiment has been to my mind so conclusive and satisfactory, that I intend drilling some quantity this year, and shall also try it with other crops besides turnips where the land is not in high condition. I can easily carry back to the farmers when delivering on it their respective millers, therefore without any cost or expense of transit; it is now selling at about 44. 10s. per ton, which is cheap for the benefit received when compared with the cost of bones, about 100. or 120. per ton, which makes it the more desirable. I would not recommend so much as six cwt. being used to an acre, but any quantity from six cwt. to five cwt. per acre, which would be at a cost of manure of about 11. 2s. 6d. per acre for an increase of *one-third more in produce*. Should others follow, as I have done, the recommendation given in the letters before alluded to, it would only be fulfilling the duty we owe one another to report the result, more especially if it should prove favorable as in the above instance.

I remain, your obedient servant,

WILLIAM MONK.

Midhurst, Sussex, April 14.

Garden Seeds.—Why don't seedsmen mark the year on their papers of seed, in order that the retailer may not impose old seed on the customers? Nothing is so provoking, particularly in a backward season like this, as, after waiting three weeks, to find no boots or onions out of ground. If the doctrine that "honesty is the best policy," will apply to one trade more than another, it is to that of a seedsmen—many of my neighbors who are not pinching of a 6d. now raise their own seed to avoid being cheated. Onion seed wants much soaking.

S. W.

Onondaga Salt.—The salt inspector at Saline has turned the tables upon the Albany Cultivator, for saying that "large quantities of lime were used in the adulteration of salt." Had the Cultivator said a little lime was used to decolor the red oxide of iron which colored the salt, he would have misled the inspector to the counter.

S. W.

Indian Corn.—At the moment when the temperance reform is doing away with the use of corn as the basis of alcoholic drinks, man has discovered the invaluable secret of turning the stalk into sugar, at a far greater profit to the agriculturist, if report is true, than can be realized from the ripened grain. S. W.

Asparagus Bed.

To J. S. who inquires what is the best mode of making and cultivating an Asparagus Bed, we answer that the whole affair, which was once hidden in mystery or rather involved a very complicated process, is now as simple as the simplest operation in husbandry.

Now your seeds in a nursery bed in drills and keep them clean of weeds the first year. The next year prepare your bed by trenching the ground fourteen to eighteen inches deep, always keeping the top soil up permost; or, if the bed is to be a large one, by trench ploughing, that is by passing twice in the same furrow with a plough, the second time with a plough without a mould board, or a subsoil plough; and manure the ground as highly as possible. Alter it is well prepared, make trenches with a spade or plough about eight inches deep and two feet apart; place your plants of one year's growth in these trenches; put in upon the plants two or three inches of good well rotted or composted manure and cover them fully with dirt. Get the finest and largest kinds of roots for planting. Keep the beds entirely clean from weeds. They may be cut the third year from the seed; and in cutting the plants, cut them obliquely about an inch below the surface. Cover the bed, if convenient, annually, in the fall with stable manure two or three inches thick; in the spring dig it with a dung fork about six inches deep, and rake the bed clean. These directions will almost insure success. If you desire early asparagus, secure a warm and sheltered spot. Some persons recommend, as asparagus is a maritime plant, the application of salt to the bed. A small amount mixed with the manure or scattered upon the bed would probably be beneficial. Asparagus well cooked, is one of the earliest and best of vegetables.

Manufacture of Paper.

Mr. Dierrey, a paper manufacturer of Ghent, has discovered that the refuse ends of asparagus make excellent paper, at half the expense of paper from rags; and that a still greater economy is obtained by mixing the pulp of asparagus with that of the beetroot.—*Eng. paper.*

Instructions against Damage to Standing Crops by Hail Storms.

In France, and some other countries of the continent, companies for the Insurance of Agriculturists from loss through the destruction of standing crops by hail storms have long been established, and have proved of great utility. In England, happily, our rising harvests are not so frequently exposed to injury from such causes, but, nevertheless, it is the part of prudence to guard against even improbable danger, when the cost is trifling. Men do not insure their houses from fire because they expect a visitation from the devouring element, but simply as a measure of wise prevention against a possible casualty.—*New Farmer's Journal.*

Feeding Cattle on Carrots.

To the Editor of the Doncaster Chronicle.

Carlton Hall, Feb. 9, 1842.

Sir.—Noticing a question in your last week's Chronicle, on Feeding Cattle on Carrots, being a means of bringing on the Ophthalmia, I beg to say, we have been in the practice of feeding cattle with carrots very freely, more particularly milch cows, and have never had anything of that disease amongst them, generally being very healthy, and I certainly consider them very healthy food for cattle and horses. Whenever they are unwell I generally order them a few carrots.

I am, sir, your obedient servant,

W. BRADLEY,

Steward to R. Rumbden, Esq.

N. B. I wish to further observe, I have never found anything to produce so sweet milk and butter as carrots.

Crater in the Sun.

Something extraordinary is at this moment passing in the sun; a sort of crater is perceived in it, which emits clouds of smoke that spread over a portion of its surface like an enormous moveable spot.—*Brussels paper.*

Wood's Plough.

With the general aim of the submission remarks we entirely concur; and we are in the same situation as to a knowledge of the grounds on which the decision of the Court rested as the writer is. An entirely different impression from what he seems to have in this matter has been given to us; as we learnt from one of the counsel engaged in the cause, that it was decided on its actual merits, and on the ground, which the Jury at least supposed to have been made out, that Wood was not the original inventor of the improvement on which his patent depended. We should with extreme reluctance do his memory the slightest injustice; and should be very glad if some of our correspondents would set us right in the case.—*Ed.*

For the New Genesee Farmer

The late decision of the Supreme Court at Cambridge, or rather the reports of that decision may induce many to regard the inventor of Wood's Plough in a different light from what he justly merits. Not being present nor having seen a full report of the trial, I cannot judge so well as some others, but I understand the patent was chiefly set aside on the ground of legal technicalities, and not because Wood was not in reality the inventor. So far as he is in real equity entitled to the thanks of his country for the great benefit he has conferred upon it, cannot be affected by testimony of hasty observers, given entirely on memory of thirty years standing, which there is every reason to believe is founded in mistake, or by the fact that he delayed one year in getting a patent. No one denies that it was by his perseverance and talent that the cast iron plough was introduced into general use, and that this, together with the great improvement he made in it, has been the means of effecting a greater revolution in the agriculture of the United States than all the improvements in other agricultural implements and machines for the last twenty years put together. At the time he obtained his patent, no one thought of denying his right to it; but instead of this, his opponents endeavored to show that his plough was of no value. But as soon as he had triumphed over this opposition, and its real worth could be no longer doubted, his fellow-citizens commenced depriving him of the advantages he had thus obtained with so much labor and expense, with a very few exceptions, and the rest of his life was one ineffectual struggle to maintain what he supposed the law of his country had really given him.

The history of American Inventors, almost without exception, affords but a melancholy picture. Robert Fulton brought successfully into use a machine which has indeed conferred wonderful advantages upon the country and the world; yet he was opposed on every hand, and attempts were by no means wanting to deprive him of the honor of the invention, by showing the prior claims of others—but who doubts to whom the right belongs? Eli Whitney, by the construction of the cotton gin, conferred wealth on the Southern States to the amount of millions on millions; yet his life was a constant succession of vexations and disappointments in maintaining the validity of his patent; and so great was the opposition he had to encounter, and so little relief could he get from courts of law, that on one occasion he found it almost impossible to prove that his machine had ever been used in the state, while one could at that moment be heard within a short distance of the court house door. Yet it is doubtful, considering the constant and multifarious uses of the plough, if even the steamboat and cotton gin together, have conferred nearly the real benefit on the country, which the cast iron plough has done.

These remarks are not made from any selfish motives, as the writer is in no wise interested in the matter however remotely, but merely from a desire to

have justice done to the memory of a man who, instead of abuse, deserves the lasting thanks of all his countrymen.

A CITIZEN.

Cranberry Rake.

(Extract from a letter.)

"In your March number article, 'Cranberries' is mentioned a Rake by which a man can gather 50 or a 100 bushels of Cranberries per day. Such a rake would be of great value here, and I hope you will procure a drawing or description of it, that will enable us to make it."

J. M. L.

The Cranberry Rake which he inquires after, is a very simple instrument, made in a form of which we give a view.

It has curved teeth about fourteen inches in length made thin and set so closely together that the berries will not escape through them, and sides with a board about the thickness of a shingle or $\frac{1}{4}$ of an inch. The teeth are made of hickory. We give the dimensions from mere sight and not measurement. They are for sale at the excellent and extensive Agricultural Ware House and Seed Store of Messrs. Jos. Breck & Co., Boston. The price cannot be much, but we do not know what it is.

On Ploughing and Fallowing for Wheat.

DEAR SIR:—I perceive that the subject of summer fallow is again attracting among our farmers, serious attention, and well it may—for the loss of the use of wheat land for the half of the time is a serious drawback upon the farmers' profits—and that is not his only loss in consequence—the sun shining upon the naked surface of the land, during the hot summer months seriously injures it—and a continued use of the practice, would after a few years entirely ruin it. But fortunately nature ever mindful of the improvidence of man—sends forth upon the surface various vegetable productions, which serve as a carpet for the protection of the soil—even weeds do some good for that purpose.

Summer fallows and the loss of the land in consequence, and a remedy therefor, has for a long time attracted my attention and observation, and some practical operations have materially assisted me in the investigations.

Of all the operations of the farmer, ploughing is first in importance, and unless it is performed in the best possible manner, no very large crop need be expected; and the inquiry is abroad, cannot a good crop of wheat be obtained by once ploughing the ground, and that too after the crop has been taken off, either by hay or pasture. I think it can be done, provided it is properly managed. But this is certain, that if a farmer undertakes the course with a common plough, one span of horses or one yoke of oxen, and it is turned up rather shallow, as that strength of team necessarily

must do—with the greater part of the furrows set up edgewise, instead of being laid flat and his furrows so narrow, that no animal can walk straight forward in one without reeling out, sometimes on one side and then on the other, the plough following the cattle, sometimes in the right place, but oftener in the wrong, to the great discomfort of the ploughman as well as his team—that no crop of wheat can be expected with such management—the wheat will be choked under that kind of ploughing with very foul stuff, and the little wheat you get will not pay for the labor expended—and with such ploughing as we see frequently about the country, it is indeed a wonder that a crop of wheat is ever obtained even after three such ploughings.

No ploughman with the best of ploughs can make good work on grassy land unless there is sufficient width of furrow for the animal to walk in it steadily and with ease to himself.

But the grand question is, what must be done to insure a good crop after hay or pasture with but one ploughing? And on smooth land as most of the land now is, by repeated fallowing? To accomplish so desirable an object, the first thing necessary, is to obtain a plough of sufficient capacity to turn a furrow at least ten inches deep and fifteen inches wide, and turn it flat over, if twelve inches deep and eighteen inches wide so much the better—and team strong enough to draw it that will give an abundance of earth above the seed to be pulverised, and be prepared for a large crop of wheat.

A gnaw wheel to the plough is not only convenient but useful in such ploughing—the extra expense attending it, over that of common and narrow furrows is not so great as would appear at the first look, to cost as much at two furrows as you otherwise would at three furrows, will be found nearly to make up the difference in the expense of the two modes.

I cannot hardly tell why; but the first time the ground is managed in this way, a good crop is generally obtained, but not a very large one—whether it is owing to its not receiving a proper degree of pulverization the new parts of the seed not being sufficiently divided, I cannot say, although it must be rich enough; from what most people may have observed in making excavations. But the second time the operation is gone through with, and ever after if rightly managed, a large and heavy crop may be expected, with but a light expense in preparing the ground—for less strength of team will do the ploughing from what it took the first time.

I am fully of opinion that the land to be kept up good and not allowed to deteriorate and to be the most profitable to the farmer in a long run, ought not to be put into wheat oftener than once in three years—be thickly seeded with grass seed the next spring after sowing, a fine lot of after growth will probably be obtained in the fall after the wheat is off—the following year seeded principally with clover, with a small proportion of other grasses, and well plastered, an abundance of hay and pasture may be obtained; the next year the best of hay may be cut from it, or pastured if preferred—and the same season again ploughed and sown with a prospect of a first-rate crop—and if manure is liberally made and saved on the farm and applied to the bare crops, regularly to each part of the farm until each part of the farm obtain its share of the manure, the cultivator will find his farm in high order—and it will be his own fault if his pockets are not well supplied. One-third of a good wheat farm managed in this way, may be sown to wheat every year, and more stock kept upon it, than can be kept on any exclusive grazing farm that can be found in this country. I am respectfully sir,

Yours &c.

THOMAS TUFTS.

Le Roy, July 9, 1842.

Two the following letters ought to have appeared in the June number of the Farmer, but did not reach us seasonably. We hope they will attract the attention which they deserve; and should be very happy to hear from the writers of them as often as they find it convenient to favor us. Our friend W. B. will assuredly give the desired information respecting Tomato Figs.

Various Inquiries.—Stearine from Lard and Oil from Corn Meal.

Ma, COLMAN—It is with pleasure I acknowledge the great satisfaction as well as instruction I receive from reading your invaluable paper. Your April No. is particularly gratifying, and is calculated to fill the mind with a deep interest, particularly the notice you have taken of the Report of the Commissioner of Patents, Mr. Ellsworth. But I could wish that some of your correspondents would make themselves responsible by signing their names to their communications. Much more confidence, I think, would be placed by your readers in communications thus sustained, and the editor would be troubled with none but such, as the authors at least considered worth printing. A plain, simple statement of all the facts relating to the subject, is what is wanted, and if that is fortified by a responsible name, so much the better. No words (unless explained) should be made use of but such are to be found in common school dictionaries, for our farmers are not all brought up at the feet of Gamaliel.

In the last No. of your paper, is a communication signed "W. B." headed "Tomato Figs," describing their valuable and luscious qualities, and stating them to be within the reach of almost every man, and stating also, that in their preparation the medicinal qualities of the fruit were concentrated. Very well, so far, so good. But why stop here? Why not tell us how to prepare the "Tomato Figs"? He would then have done us a real service, and for one, if on trial I had found he had told us the truth, I would have hailed him as a benefactor. But I hope he will take up the subject again, and tell the whole story, and, by way of setting a good example, put his name to it.

I mention these things, not for the purpose of carrying or fadling fault, but to show that we farmers want facts more than speculation. We want truth, the whole truth, and if possible, nothing but the truth upon subjects communicated to us. An imperfect or erroneous statement of facts, sometimes injures the circulation of an Agricultural paper more than if the space occupied by it had been left blank.

Stearine from Fixed Oils, or Oils obtained from the seeds of Plants.

"The chemical nature of soap has of late years been elucidated by the labors of M. Chevreul. This chemist has found that fixed oils of fats are not pure proximate principles, but consist of two substances, one of which is solid at common temperatures, while the other is fluid. To the former he has applied the name of Stearine (suet) and to the latter Oleine (oil). Stearine is the chief ingredient of suet, butter and lard, and is the cause of their solidity, whereas oils contain a greater proportional quantity of oleine, and are consequently fluid. These principles may be separated from one another by exposing fixed oil to a low temperature and pressing it when congealed, between folds of bibulous (absorbing) paper. The stearine is thus obtained in a separate form, and by pressing the bibulous paper under water an oily matter is produced which is oleine in a state of purity."—Turner's Elements of Chemistry, 4th American Edition, from 3d London Edition, Philadelphia, 1832, p. 485.

Query.—Is or is not this process the same with that practiced in Alton, Ill., for extracting Stearine from the Oil of the Castor Bean, of which candles is made?

Again, Stearine from Lard.

"The method of preparing stearine and oleine from the vegetable oils has been already described

"(page 485) and the same process which originated with M. Bencnot, is also applicable to hog's lard. This process by which M. Chevreul obtains these principles, is by treating hog's lard in successive portions of hot alcohol. The spirit in cooling deposits the stearine in the form of white crystalline needles, which are brittle and have the aspect of wax, fuse readily when heated, and are insoluble in water. The alcoholic solution, when evaporated, leaves an oily fluid which is oleine."—*ibid.*, p. 544.

Here are two methods of procuring Stearine from Lard, of which, according to Mr. Ellsworth's report, candles are made worth 25 or 30 cents per pound, and one by which the same substance is obtained from vegetable oils for the same purpose. Whether either of them is the best that can be devised, remains to be seen. I hope we shall hear more on the subject.

But the subject in Mr. E.'s report, or so much of it as you have noticed in your paper, appears to me to be the most extraordinary, and if the results of Mr. Webb's experiments and the deductions drawn from them by Mr. Ellsworth are not deceptive, will undoubtedly prove of great importance to the people of the Northern and Western parts of the United States.

Mr. E. does not give us particulars, but says "a minute account of these experiments can be furnished if desired." I hope you will desire it, and also publish it. Let us have facts; there is still immense room for facts in the science, yes, science of Agriculture. We have not yet learned even its first rudiments.

Oil from Corn Meal.

I am informed that Oil from Corn Meal is obtained by a mercantile firm in this state to a very considerable extent. I am told they are largely in the distilling business, and purchase large quantities of corn and obtain the oil from the meal while in a state of fermentation, by skimming. The meal is afterwards distilled, by which operation, as my informant said, the oil they saved was clear grain above that of other distillers. I presume this is the company to which Mr. E. refers in his report, as wishing for the privilege of supplying the light houses on the Lakes with oil.

Our fruit trees are now in full blossom, and the earliness of the season keeps the owners in constant fear that a frost may come and disappoint their best hopes. The man who can devise some cheap method, within the reach of common farmers, whereby orchards could be protected from early frosts, would deserve well of his country. It is a subject which I hope your correspondents will take into consideration.

Yours &c.

J. CROCKER.

Wooster, Ohio, 1842.

Mr. COLMAN—In your May number of the Genesee Farmer I discovered an article headed "Sugar from Indian Corn and Stearine from Lard." On reading the article I was much disappointed in not receiving any information on the method of obtaining Stearine from Lard. For the past two months I have devoted some time and pains to the investigation of the best method of obtaining stearic, margaric and oleic acids, and stearine and oleine from lard and tallow. The method which I found to be the best for obtaining the above acids from lard and tallow, is this: boil the fat in water for four or five hours, with a sufficient quantity of lime to form an earthy soap. During this process, the elements of the fat are so arranged as to form the acids, which combine with the alkaline earth and form with it their respective salts. These salts or earthy soap is decomposed in a large quantity of water by sulphuric acid, the acids being thus liberated, rise to the top of the water, which, when cold, is to be taken off, shaved fine, and then subjected to strong pressure, when the oleic acid will run off in a substance resembling oil, and leaves the stearic and margaric acids in the press, a substance

very much resembling spermaceti, which, when made into candles, I found to be disposed to melt and run down; this, however, might be owing to its not being sufficiently pressed, as the press which I had was not very good.

If the process which you referred to in your last number is any thing like the foregoing, it is the last-mentioned acids that are obtained by it and not the stearine and oleine, as you there stated. The stearine and oleine are obtained by a different process. I have tried several experiments for the purpose of obtaining them, but as yet am not satisfied with the results. From what investigation I have made on the subject, I think I can soon satisfy myself with a process for obtaining them.

My object in writing to you is to obtain information on the subject. If you have a pamphlet on the subject you can spare, I wish you would send me one. If not, be so good as to write me those things that are practical.

Yours &c.

JOHN McLEAN.

Jackson, Michigan, 1842.

P. S. The process which I have given you in part in this letter, was patented in England in the year 1823.

J. McL.

We have sent the pamphlet of the National Agricultural Society to J. McL., and hope it has been received.

Cattle Shows, Fairs, and Ploughing Matches.

We subjoin a notice of the times of holding the several Agricultural Fairs, which come within our knowledge, within the district where our paper principally circulates, and shall keep it in until the times arrive. We shall be obliged to the Secretaries of the different Agricultural Societies in New York, Ohio, New England and Canada, if they will give us (post paid) the notices of their respective fairs.

CANADA.

Durham, Bowmanville, Oct. 18.

Northumberland, Grifon, Oct. 12th.

Over-Production.—It would seem, that whatever can be produced by the steam engine power-loom and other improvements in machinery, has been generally, and in some articles of manufacture, sadly overdone in Europe and the United States; but this only adds to the farmer's comfort and wealth, as whatever depends solely on the hands, the plough, or the team, is not depressed *pro rata* in price and demand. When I see a farmer's wife exchanging a pail of butter, a basket of eggs, and a badly skimmed cheese, for calico and muslin enough to clothe all her children, while her husband stands by complaining of hard times, and contending that the dealer shall add thread and tape gratis, I am ready to exclaim with the Mussulman, "God is just: he gives to the rich man only one belly."

EXTRAORDINARY.—Three hundred large Hogs, brought from Kentucky by way of New Orleans, were offered for sale last Monday at Eyrington, Mass. They remained unsold. What next?

New Wheat is selling at 50 cents per bushel in Cincinnati.

From the Mark Lane Express for February.

Comparative Condition of the English and French Laborers.

To the Editor of the Mark Lane Express:

Sir—As at this moment all Englishmen are occupied with anticipated alterations in the corn laws, the relative modes of existence of the British and foreign laborer are often compared. I am aware that no man understands better than yourself the comforts or the wants of the farm servant in England; but as, during your sojourn and travel on the continent, I think you did not visit the West of France, give me leave to point out the situation of a day laborer in that country (say Department de la Mayenne). He earns twenty-two sous a day, 11d., (nearly), his ordinary food consists of black bread made of buck wheat, and a soup composed of salt and water, in which a few cabbage leaves have been boiled with a little grease—of this he eats three times a day; on Friday a certain quantity of buck wheat flour is boiled into a kind of posie and eaten, seasoned with salt. On Sunday, sometimes, he has a little bacon, but fresh meat (excepting a bit of liver or the inside of a sheep) he does not eat, since he makes wheaten bread. This general beverage is water, sometimes, when at a good house, he gets a little clear water, of the most pleasant description. A woman earns four sous a day, and her food which is soup such as I have before described, and four milk eaten with black bread. The man's dress in summer is a coarse linen jacket, trousers, and shirt; the hemp with which they are made has been grown in his garden, spun by his wife, and woven by a neighboring weaver; that used for the outer garment is dyed blue, and the shirt is left unbleached; he wears no stockings, a red or grey woolen night-cap covers his head. In winter the same, only substituting homespun wool for hemp, and a wisep of straw in the boots to keep his feet warm; three pairs (of these last) per annum cost eight sous a pair, keep him well shod. He possesses a hat, pair of shoes, socks, and a neckcloth, but these he only wears on Sundays and fete days. His dwelling is stone built, a ground floor, the window place is iron-barred with a strong inside shutter, and totally unglazed; the door is divided in two, the upper half and the shutter are generally left open for light; a bed or two in the corners, on wooden frames, and the floor is of earth.

This is not an exaggerated statement, but one drawn from real life. My only wish is that when the comforts of the foreign laborer are vaunted, the real state of the case may be known by those interested in the welfare of our own men, but whose pursuits or occupations have not permitted them to make personal observation. There is a noble emulation now existing in England for the improvement of agriculture, and it is not a compliment when I say that you have lent a powerful aid to its progress. But England could feed her people, and have to spare, I have no doubt; but to accomplish that great good, her millions of acres of yet un reclaimed wastes must be given up to spade husbandry, her pastures must be ploughed, and her cattle be stall-fed. Forgive my trespassing so long on your time.

Yours, &c., C. S.

POLAND.

BY MAJOR TOCHMAN.

Money is very scarce in all parts of Poland, the laboring class is in a wretched condition, and uncleanliness is to be seen even in the magnificent palaces built by their fathers. Many a Pole, who possesses thousands of acres of land, and who has thousands of bushels of wheat in his granaries, finds himself often under difficulty to pay taxes and arbitrary contributions. Consequently every thing that the laborer and the soil produce is very cheap—wheat the foreign article of the last being obliged to pay heavy duties, to maintain their non-commercial policy.

In the last two or three centuries before the dismemberment of Poland, copper money was almost unknown in Poland—silver and gold were in circulation—the people scarcely knew any other money than dollars and ducats, (a dollar was of the same value as the American; a ducat is a gold piece worth \$2.50); now a Polish florin (*zloty polski*) which is equal to one shilling of the State of New York, is divided into thirty very small pieces of copper, called "gorze," and for one such piece of copper, that is to say, for the thirtieth of a shilling, they have a loaf of bread sufficient for the breakfast, dinner, and supper of an American gentleman. The price of wheat is from 18 to 25 cents a bushel; rye, barley, and oats, sell at two thirds or a half of the price of wheat. In some parts of Poland, incorporated with Russia, those articles

may be got at a much lower price; whilst for coffee and sugar they must pay from 18 to 25 cents a pound, and for tea from 75 cents to \$3.

The consequence is, that the foreign articles, even of the first necessity, as the above are used by a very few families, in proportion to the population of the country; scarcely one person in a hundred is rich enough to use coffee and tea in Poland, since it has been deemed. An owner of two or three hundred acres of well cultivated land, seldom makes use of any article which does not grow on his soil. As to the laboring class, they never see any. The produce of the soil feeds and clothes them.

A common laborer gets in Poland from 6 to 124 cents per day; a mechanic seldom more than 25 cents; a female servant, in the country, has from 37 to 75 cents per month; a male servant from 50 cents to \$1 per month. In the cities, the wages of servants are about one fourth higher. The clothing of the laboring class of both sexes, is comfortable, but very poor, made of linen and woolen cloth, and furs of the country. The whole dress of a country female per annum costs from 3 to \$6; the dress of a laboring man from 1 to \$2, including shoes and bonnet. A pair of shoes used by a laboring female sells from 15 to 37 cents; and a pair of boots of a laboring man, from 37½ to 75 cents. As to the clothing of a lady, this costs nearly as much as in the United States; the cotton and silk stuffs, the ribbons and other articles necessary to make ladies' dresses, being almost of the same price throughout Poland as here. It is the same with regard to the dress of a gentleman,—only that the ladies' shoes and the gentlemen's boots are cheaper in Poland: such shoes as we pay here \$1.25 for, are selling in Poland for from 25 to 37½ cents; for such boots as cost here 7 or \$3, they pay from 2 to \$2. But to get boots for \$2, they must sell from 12 to 15 bushels of wheat, and the dress of a lady, worth only \$20, will cost them from 80 to 100 bushels of it. A farmer, who has 2,000 bushels of wheat for sale, can buy a silver watch for himself, but not one for his wife; while had he, before the dismemberment of Poland, sold 2,000 bushels of wheat, neither he or his lady and half a dozen of daughters would look at gold watches, not set with diamonds, or at least, with rubies.

The cattle, flocks, and herds, are also very cheap. A milk-cow sells at from 2.50 to \$4; an ox for slaughter from 10 to \$20. A horse, such as we pay here \$70 for, is worth in some parts of Poland about \$25; in the parts of the country incorporated with Russia, such a horse is worth only from 7 to \$12. A common sheep sells from 13 cents to one dollar. These called "merino sheep," introduced from Spain, are sold from 20 to \$100.

Wind Power Machine.

MR. HENRY COLMAN—I have this day received the enclosed letter from Captain Glover, giving me a description of his Wind Mill; but as he observes in his postscript, "but little insight can be had from the description." Yet I am persuaded that the view of the model for one minute by any mechanical genius, would impress its importance on the mind over all other forms for Wind Power.

I am respectfully, yours &c.

O. WHITE.

Brookline, June 25, 1842.

Roxbury, Mass., June 24, 1842.

I now will describe, as well as I can, my Wind Pover. It is adapted to be placed on the roof of a building, consequently occupies no room wanted for other purposes; it consists of 4 arms, to which is attached the wings, composed of thin boards, cross lined with the same, and fastened together with rivets or nails, and is hung to the arms with staple hinges about 3 by ½, and is supported by a spring, of which there are several sorts. The one I have adopted is somewhat like that of the main spring of a watch, wound round the arm, and extended to the wing, so that when a greater force of wind strikes the sail than is required, this spring gives way and diminishes the surface in exact ratio to its force; hence it cannot revolve with any more speed in a gale than in (as we sailors say) a royal breeze. It tends to the wind like a weathercock; has no canvases or cloth for sails; no reefing, no furling of sails; requires no attendance,

and by a simple brake is made to stop. A spindle, 2 bevel cogs, and shaft, are all that is necessary. The latter is brought down through a pump log to the loft where the drum or cog-wheels is to be attached, as the case may require.

For grinding corn a simple cog wheel will give motion to as many run of stones as can stand around it, and be thrown out of gear at pleasure. For sawing, &c., a drum can be used with bands. When not wanted in motion for any considerable time, the wings can be hooked or pinned back. The power is in proportion to its size, and if found too much or too little in its operation, it can be regulated by extending or contracting the spring out or in on the wing; out to increase, and in to decrease the power. The arms or wings fly to leeward. The fan or wind board is about twice the width of the wings, secured to the frame of boards on each side, similar to a barn door. Any carpenter can make the whole, except shaft, spindle and cog wheels, which are of iron.

P. S. You can get but little insight by this, the only way is to see the model.

From the Boston Daily Advertiser.

The last Monthly Chronicle contains a statistical account recently published, by which it appears that the agriculturists of France possess the following number of animals:

Cows	766,310	6,681,000
Merino Sheep	30,845,532	
Common Sheep		

Horses and Mules	31,612,162
Pigs	1,635,000
	2,900,162
	43,449,162

In Mr. McCulloch's statistics of the British Empire, published in 1839, the number of oxen and cows in Great Britain is estimated at 5,220,000. Sheep and Lambs in England 26,148,463.

do do Scotland 3,500,000

Horses, probably including Mules 29,648,463

Pigs, the number not stated by McCulloch, but are estimated by another writer, including those of Ireland, at 18,000,000

do do 54,368,463

By the census of 1840 there were found in the United States

Neat Cattle 14,971,556

Sheep 12,311,394

Horses and Mules 4,335,669

Swine 26,301,298

94,919,622

Supposing the foregoing estimates of the number of these animals in Great Britain and France to be correct, it follows that there are in the United States upwards of three millions of neat cattle more than in both Great Britain and France together. France has upwards of twelve millions of sheep, and Great Britain upwards of ten millions more than the United States.

If to the number of horses in France used for agricultural purposes be added, three hundred and forty four thousand, for the cavalry and other uses, it gives for that kingdom a total of two millions—these added to the fifteen hundred thousand in Great Britain fall short of the number in the United States by more than eight hundred and thirty-five thousand. The Swine in the United States exceed those of France, Great Britain and Ireland together by about four million four hundred thousand.

From the above it will be seen, that with the exception of sheep, there are many more of each of the other animals in the United States than in France and Great Britain together.

Q.

The unborn starz was penned in an Album at Niagara by Lord Morpeth, on his late visit to the Falls. Every generous mind, and every friend to the two countries must cordially join in the prayer.

There spend their rage, nor climb the encircling steepers, And 'till the conflict of thy surges cease

The Nations on thy banks repose in peace."

Protecting Home Industry.

MR. ELLISON—I observe, by the freedom of your own remarks as well as by the conflicting sentiments of correspondents admitted to your columns, that you are no enemy to the free discussion of all questions connected with the general prosperity. On the subject of a tariff, I see two articles in your Farmer for June—one of S. W., the other of Old Humphrey of the Genesee. Plain working folks like me, don't know much about "the theory of a Protective Tariff and retaliatory duties," or indeed about theories of any kind; and if it would not be deemed rude, I would venture to say to S. W. that, after looking over several of his well polished communications, a number of us have come to the conclusion that if he were a practical working man, he would find less time, and perhaps have less disposition to theorize. The last I heard of him, he was with Zelia in the Saloon, contrary, as I understand it, to express regulation. But if I was you, I would not make a fuss about it—better let him be—for that, of all places in your boat, is the very spot for him.

The first statement made by S. W. which I judged material to the support of his anti-tariff theory, astonished me, for it was indeed news to me, and I think will be to you, that New England, the great workshop, has never advocated a high tariff. I have all along supposed that she cried out as loudly, as unitedly, and I may add more effectually, for a tariff than Pennsylvania; and that she has steadily and perseveringly pursued a policy forced upon her by non-intercourse and embargo measures, and in which she was induced to embark much of her capital to supply the demand created by these measures, and rendered apparent by the war which shortly succeeded them. And why is it that factories, not a few among her cities or factories too, are closed, and the hands unemployed? Why, but because she cannot stand competition with the pauper labor of the old world—because the protection which her manufactures have enjoyed, and under which all have lived and many of them flourished, is about to be withdrawn? And does not New England know all this—and knowing it, has she not sought from Government the boon of that protection that ensures her prosperity? I cannot doubt it; for the Yankees, I take it, are among the last men on earth, to let any blessing slip by them unenjoyed because unasked. But near the close, S. W. says he is in favor of "a tariff ample for the purposes of revenue, framed with such discrimination as will favor both revenue and protection to our home industry." If Pennsylvania, "in the dark hour of her distress," asks for any higher tariff than this, I never heard of it, and you are welcome to say that I think her very unreasonable. But says S. W., "I always go for encouraging domestic industry and building up a home trade, as a certain market for the farmer." Them's my sentiments, Mr. Editor, and though S. W. and I may not have agreed entirely by the way, yet so cordially do I concur in his closing remarks that we part the best of friends.

At odd spells, between ploughing and pulling stumps, I have attentively read your friend Old Humphrey, and am by no means sure that I understand him. He speaks approvingly of a tariff for revenue only, and immediately adds that it should be imposed with such discrimination as to protect such of our manufactures as most need it. Now so far as I understand, this is about all any body wants. And yet in the next paragraph he seems to speak of a protective tariff, as evil only, and that continually. I cannot understand this, and without desiring to censure the old gentleman, I must say I think him a trifle metaphysical, according to the Scotchman's definition of it,—“when ye hear a man talking and cannot understand what he means—and when he that's talk-

ing does not understand what he means himself, that's metaphysics."

Not long ago I heard a laboring farmer address a meeting of laborers on the subject of protection to home industry. He started with the position, that the habit of business that contributed to the thrift and prosperity of a family, had no necessary connexion with its number; and consequently that those prudential rules and economical habits that would create and secure the prosperity of a family of five or seven, were in general equally applicable to our great American family of seventeen millions. Every economist knows at the end of every year whether he can make the two ends meet. If, after disposing of the produce of his labor to the best advantage, he finds that he still owes for articles purchased, and that the balance of trade is thus against him, or in homely phrase, that he has bought more than he can pay for, he is forced to the conviction that he can recover from the embarrassment and prevent its recurrence *only* by selling more or by buying less—or best of all, by doing something in both ways. For so surely as he continues to buy more than he sells, and year after year runs behind hand, so surely is he bankrupt. When the farmer can pay the shoemaker in the produce of his farm he had probably better make the exchange than make his own shoes; but if he requires in payment that which the farmer does not make or cannot produce out of his labor, he had better sit in the house where he can do without shoes, than buy them with the certainty that they will be worn out in travelling the road to inevitable ruin. These positions, it was argued, had an application to every variety of human intercourse, and were as true of families as of individuals, and of nations as of families.

Protection to manufactures, by affording higher wages, would draw off from a redundant agricultural population, so many as would equalize production and consumption, thus rendering each one's labor more profitable—for it is clear, if you make consumers of those who are now producers of food, that agricultural labor will be better paid. Protection to home industry will produce on the currency those beneficial results which are confidently predicted of National Banks, Sub-Treasuries and Fiscal Agencies. So long as we continue to buy more than we sell, so long will there be a constant stream of specie running out of the country—for specie is the only article with which we at the North can pay foreign debt. Cherish home industry, and you will have no call to send specie abroad, after existing debts are paid off. Divert this exhausting drain—dam up this ceaseless current, and retain it with its constant accumulations in the country, and you have the only safe and reliable basis of a sound and healthful paper circulation. The country is thus rendered truly free and independent—a position demanded not less by our interest than our national honor. Such were some of the views of my friend, and I thought he hit the nail on the head.

Yours truly,

June 27, 1842. JOHN FARMER.

From the Salem Gazette.

Leather Business of Danvers.

The following statement has been obtained for our use, and we take pleasure in laying before our readers the statistics of so industrious a community as that of Danvers. The well known accuracy of the compiler imports to it perfect authenticity.

A statistical account of the Shoe and Leather business in the town of Danvers for the year 1841, compiled from the returns made by committees appointed in each department of the business, who reported specially what was done by each person engaged in it.

1. Boots and Shoes, manufactured,—224,000

Estimated value, when ready for market, \$650,000
40 per cent of this is labor applied—1255 males are constantly employed, and 946 females.

2. Tanning and Currying—373,800 sides of leather.

10 per cent of labor applied in the process of tanning,—20 per cent of labor applied in the process of currying upon leather. A large proportion of the leather tanned here is also curried. 329 males are constantly employed in this business.

The Real Estate, consisting of tanneries and mills used in this business, is valued at \$123,000. 6500 cords of bark are used in the tanneries, estimated at \$8 per cord, when delivered at the yard, \$50,000, 9 10ths of this is the result of actual labor applied. The transportation of the bark from Maine to Massachusetts employs 15 vessels of 80 tons each, and 60 men. The transportation of hides from South America employs 5 vessels of 200 tons each and 50 men. In addition to the above, citizens of this place are concerned in tanneries in Maine and Vermont, from which they receive leather ready for the market, of the value of \$200,000

3. Manufacture of Skins—150,000 dressed annually.

Estimated value when ready for the market, 90,000

40 per cent of this is labor applied,—44 males constantly employed.

Gross amount of the value of materials brought to market annually by our manufacturers,

\$1,732,900

The whole number of persons employed as stated above is 2630. Supposing one third of the next proceeds to be applied to a compensation for their labor, this would give about \$214 to each person, not by any means an extravagant compensation for their labor. It is not pretended that the amount of capital employed is as large as the sum above stated; because some of the articles are twice estimated.

Such for instance is the case with the leather purchased by the currier of the tanner. It will also be remembered that a large part of the stock worked in the shoe factories is purchased in the New York and Philadelphia and Baltimore markets.

The foregoing estimates are the best approximation to the facts, that I have been able to obtain from an examination of the returns of men practically engaged in the business. Throughout it has appeared to me they were not disposed to overrate their business. A more sober, industrious, and mind their own business class of people, than the manufacturers of this place, it will be difficult to find in any community.

I hope sir, that the above statements, hastily sketched, will be found a satisfactory answer to your inquiries. Very respectfully and truly yours,

Danvers, March, 1842 J. W. PROCTOR.

On the Effect of Carrots on Horses.

From the Editor of the Mark Lane Express:

SIR—In answer to a query in your excellent paper of the 10th inst., respecting feeding horses on carrots, I am unable to give your correspondent any lengthened experience on the subject; but since I have given my horses (twelve in number) carrots, I have not perceived any ill effects from them, neither have I ever heard the root accused of injuring horses' eyes before; but the chief reason of my replying to your correspondent, is to inform him that the parsnip, a root having great affinity to the carrot, is thought to have this effect, as he will perceive by the following quotations from Quyle's Agriculture of the Islands on the coast of Normandy, drawn up for the consideration of the late Board of Agriculture. Under the head, parsnip in the Island of Jersey, he says:—"Horses eat this root greedily, but in this island it is never given to them, as it is alleged when kept on this food their eyes are injured." Again, in the island of Guernsey, he says:—"To horses, parsnips are frequently given, and have the property of making them sleek and fat; but in working, they are observed to sweat profusely. If new, and cut sufficiently small, no other ill effect results, except indeed, at one period of the year, towards the close of February, when the root begins to shoot; if then given, both horses and horned cattle are subject, on this food, to an inflammation in the eyes, and epiphora, or weeping; in some subjects perhaps producing blindness." Trusting the above extracts may prove interesting to your correspondent. I remain, &c.,

January 24th. DEVONSHIRE FARMER.

July 26th, fair; 27th, fair; whortleberries ripe; 28th, a little hazy; ripe peaches and apricots in mar-
ket; 29th, green corn in market; 30th, cloudy in
the morning; strong S. W. wind; commenced rain-
about 2 o'clock, P. M., and continued to rain un-
til the next morning; wind changed about the time it
began to rain to N. W. and N., about sunset to N. E.;
the greatest rain this year. The temperature of the
month has been about the same as last year; being
this year, (monthly mean,) 66.94 degrees—last year
66.79 degrees. The greatest heat, the 19th, ther. 91
degrees,—last year the greatest, the 24th, ther. 96
degrees. Rain gauge, July, 1842, 3.69 inches; ad.
1841, 4.58 inches.
August, named in honor of the Emperor Octavius
Augustus.
Aug. 1st, quite cool; rained a little about 2, P. M.
Tomatoes ripe. 2nd, fair, and continued so until the

5th; 5th, commenced raining a little after noon;
6th and 7th, fair; 10th, a thunder shower a little
south of this; 13th, dense fog till 9 o'clock, A. M.;
14th, foggy early in the morning; 15th, smoky dur-
ing the day; 17th, showers this P. M.; thunder and
lightning in the evening; 18th, gentle showers this
P. M.; 25th, very little rain.

AGRICULTURAL INTELLIGENCE.
MONROE COUNTY AGRICULTURAL SOCIETY.—The
Executive Committee and the Town Committees are
particularly reminded of their meeting appointed to be
held at the Arcade in Rochester, at 10 o'clock, A. M.,
on the 15th of the present month. It is confidently
expected that this meeting will be fully attended, as
arrangements are then to be made for the Show on the
13th and 14th of October. Other members of the So-
ciety it is hoped will attend on that occasion. The
spirit and success with which the show shall go off,
must depend entirely upon the interest which the far-
mers manifest in the matter; and the farmers of Mon-
roe county should not permit the greatest and best in-
terest of the State and County to lag or retrograde, for
want of their cordial cooperation. The town commit-
tees and others are specially reminded of the necessity
of their making returns of the monies collected, that it
may be determined to how much we may lay claim
from the State Treasury. The latter depends wholly
upon the former.

**Rules of Premiums and Forms of Certificates
of the Monroe Agricultural Society.**

The necessity of exactness in all cases of competi-
tion for prizes is obvious to every one; and in all cases
of agricultural experiment, where the principal object
is not the reward of the experimenter for his success,
so much as the gathering instruction from what has
been done, is equally apparent. Without this, the ex-
periments and results are worth very little.

As much inconvenience has resulted from a deficien-
cy in these returns or from great informality, it seems
extremely desirable to give to the farmers such forms
and examples as are adapted to the purpose; and notice
particularly the points to which, by law, the inquiries
of the Premium Committees will be directed.

The following forms of certificates were drawn up by
our friend L. B. Langworthy, and have received the ap-
probation of the Executive Committee. These certifi-
cates can easily be copied by any farmer and presented
to the Secretary of the Society.

I. This certifies that I this day measured a field of
belonging to of
in the county of Monroe; and found it to contain
acres rods, in which I again measured one
entire piece containing acre rods and
staked the same correctly.
184
Sworn to and subscribed before me
this day of 184
Justice of the Peace.
H. This certifies that we assisted to harvest the
whole of the crop of grown upon the above
land as surveyed and staked out by and

on measuring the same find the yield to be
bushels lbs, which measurement we know to be
correct and true.
Owner.
Assistant.
Sworn to and subscribed before me
this day of 184
Justice of the Peace.

Competitors for premiums on crops must give written
answers or statements in regard to the following points.
The nature of the soil on which the crop was grown;
whether clayey, sandy, gravelly, or loamy; whether
abounding in limestone or gypsum, or any other par-
ticular mineral; whether high or low, wet or dry;
whether drained or not; and if drained, how?

The condition of the land before this crop was
planted.
The crop which preceded it.
The amount of the next previous crop and the ma-
nure applied to it.
The manure, if any, applied to the crop for which a
premium is claimed; its kind, condition, and quantity.
Time and frequency of ploughing, harrowing, cul-
tivating, hoeing, &c.
The quantity of seed per acre, which was sown—
mention the kind and preparation of the seed, and the
time and manner of sowing.
Time and mode of harvesting and cleaning the crop.

It is necessary likewise to state the whole expen-
se of the crop; including the value of the manure; cost
of seed; number of day's works of man and team of
two horses; or the cost of the whole labor applied in
sowing, cultivating, harvesting, and preparing for use
or market; or the whole cost, rating the labor of a man
at 75 cents, and of a team of two horses at one dollar
per day.

Wheat Crop.
A good deal of wheat in Western New York has
been threshed and brought to market; and we are
warranted in saying that the crop, though abundant
and in general in good order, has not equalled the
early expectations and calculations by one quarter, in
many cases by one third less. Much of the wheat,
likewise, which has been brought to Rochester, has
evidently been damaged by being cut in too green a
state and afterwards not sufficiently ripened or dried.
This is a very serious matter. Early cut wheat will
undoubtedly make more and sweeter flour than that
which stands too long, and will yield more weight of
crop, but this presupposes that it is not cut too early,
and in the next place, that it is most thoroughly made
in the sheaf or stook. In some places the wheat suf-
fered from rust, and in reference to the inquiry re-
specting the use of rusted straw, one of the best far-
mers in the state expresses his experience that cattle
will not eat much of it, and his conviction that what
they do eat will injure them.—Ed.

Sale of Durham Stock.
We beg leave to refer our readers to the Great Sale
of Durham Cattle advertised to take place at the Ris-
ing Sun, three miles from Philadelphia, on the 8th of
September, instant. There are several animals of the
highest pedigree and character. The catalogue may
be seen at the store of M. B. Bateham, Rochester.

IMPROVED AGRICULTURE.

At the late meeting at Bristol of the British Royal Agricultural Society, Mr. Smith of Deanston, the author as he may be called of the Improved System of Thorough Draining and Subsoil Ploughing, was called upon to explain at large, his views and practice in a public lecture. This was done without writing, and has been reported at large in the agricultural press. We have condensed it from the Mark Lane Express, but have taken care to omit nothing that is essential to a full understanding of the subject. It is full of important matter, and will be read by every intelligent farmer with the deepest interest. The results of this system are beneficial in the most extraordinary degree, and bid fair almost to revolutionize the husbandry of Great Britain. The results are not more extraordinary than they are profitable, as it appears from the most undoubted facts, that while under the old system, a Scotch acre of land in a lease of 18 years would, after paying all the expenses of cultivation and rent, leave a profit of only £5. 14s. stg., for the whole time, and at the same time the quality of the land become deteriorated; under the Improved System, the land itself would be left in a highly ameliorated condition, and the actual profits for the same time, after expenses were paid, would be £64. 14s. sterling.—Ed.

LECTURE BY MR. SMITH, OF DEANSTON, ON DRAINAGE.

Delivered before the Members of the Royal Agricultural Society, in the Theatre of the Philosophical Institution, Bristol, Wednesday, July 13, 1842.

(From the Bristol Mercury.)

After apologising for the alteration of the time of lecturing, Mr. Smith proceeded:—

The dryness of land is of great importance—in fact, the dry condition of the soil is the foundation of all good husbandry. It is beneficial to the working of the soil; to the after-growth of plants. There is scarcely any labor of agriculture which is not facilitated by the dryness of the soil. If we find a tree stronger than his neighbor, we shall find that there the soil is deep and in a dry condition. If we see a stronger and darker-colored herbage growing on the hill side, there the soil will be found deep, and in a dry condition. There is not one of the various soils of the United Kingdom which will not be much improved by being placed in a dry condition, if they are not so by nature. Even on a subsoil or gravel or sand, the introduction of the thorough drain system would be beneficial, but so general is only a small portion of that sort of soil in this country, the greater part being super-imposed upon a wet soil, it becomes of the first importance to improvement in agriculture that means be taken to render the soil dry. Many attempts have been made with that view, but until the introduction of the thorough drain system, there was not the power of draining land, on whatever subsoil resting, and rendering it completely dry. The purpose of this lecture is to illustrate the principles on which this system acts; then, to show the advantages in carrying on the different processes with respect to the various crops; and then to explain the modes employed to render this drainage effective.

[Mr. Smith here illustrated by a diagram, his method of thorough draining; the soil, the subsoil, the drains, &c., being represented.]

In relating to two lines, representing the direction of drains, he had drawn one at a greater inclination than the other, to show the advantage of making the drains deeper than they generally were. The prevailing practice was to make the drains two feet deep, but he preferred an additional six inches—it was of great importance to allow the water to go off as quickly as possible, and this advantage was secured by cutting the drain to a greater declination. People suppose that at a great depth water would not go off at all, but this was a mistake. Another advantage from a deep drain was that it allowed the whole bank of soil to become completely dry, and it consequently required a very heavy rain to wet it. The action of the atmosphere too required to be taken into account. He would not enter upon the chemical question, but it was well known that soils were much improved by the action of the air, and this advantage could only be secured after the water was withdrawn.

To render the field completely dry, a great number

of drains should be cut, and they should be laid off in parallel lines beginning at the highest side of the field. This secures a thorough drying. When the lines run parallel, much greater effect is produced than when they are drawn across. When drawn across, the drains may catch the water, but it does not run off so readily.

The distance at which the drains should be placed, will depend on the soil. If the field has been subsoiled, the plough will form artificial channels in the soil below. If it is a stiff soil, it will keep long upon the surface; the more free the soil is, the greater tendency it has to allow the water to pass; so that on a stiff soil, such as the stiffer clays, taking into account the nature of the subsoil and the soil itself, about the same drain will serve on all soils. The distances are generally from 15 to 20 feet: in some soils individuals have put in the drains at 12 feet; but that is, in some degree, throwing away money. From observations which I have made myself on all sorts of soil, I recommend about 16 to 20 feet as the distance from one drain to the other.

The way I usually proceed in draining is, first, to find a good bottom-level to run the drain into. In some parts of the country there is difficulty in getting an open level to carry off the whole water of the district; but by a proper engineering it may be accomplished in most situations; because it is found that if proper channels are executed, a larger quantity of water will be discharged with a very small fall. In an endeavor to carry off water, I found that in a drop of four inches in a mile, thirty feet wide and six feet deep, I could discharge 300 tons of water per minute; which is much more than would fall in a very extensive district indeed, 160 that if means be taken to carry off the main level, a fall may be had.

I should make the great main drain, if possible, about four feet deep—three feet six inches will do; but in order to have a drop from the one drain into the other, I make the main drain four feet deep, the receiving drain three feet deep, and the parallel drains two feet six inches. When there is any rise in the ground, or any hollows over which the water cannot very well flow, it is necessary to make a cad's drain. That should be made about six inches deeper than the other drains which fall into it; then running on, it discharges itself into the main drain.

As to the manner of executing the drains, various modes are recommended, and on looking to land which has been drained a great many years, where the draining has been performed carefully, all the different modes employed for the purpose of keeping the drains open have been effective. A great deal of the want of effect in the duration of drains has been owing to bad execution. In some instances fagots have been introduced for the purpose of preserving the openings of the drain, and these have been found to continue and to preserve the openings in a perfect state for nine—in some instances, for twenty years.

In Scotland the peat-top is frequently used to form the tiles for drains. It does well in clays which are pretty stiff, but not so well in softer soils. In some sandy soils, the sides not being sufficient to resist the pressure of the top, the tile gradually sinks down and closes up the drain.

Another mode of filling drains is by stones broken into the usual size for making roads. Much has been said against the use of this sort of filling, but when properly executed, the work is as durable as can be required. Where stone can be had, and tiles are expensive, I should prefer it to the tiles; it prevents any vermin from travelling in the openings of the drain, such as rats and mice, which do a great deal of mischief. The great point is, to be careful in covering over at the tops. As soon as wet comes, the sand and other materials effs down into the stones, and they are choked up. I have found drains carefully executed completely destroyed in the course of a couple of years, if drains are packed that the water falls down on both sides, the parts over-lapping each other, there is no opening whatever for the sand to find its way down. If drains are carefully cleared in this manner, I will warrant their duration for almost any period of time. I have executed myself about 130 miles of drain in this way, and have had them all filled with stones; many of them have been done 15 years, and there has not been a single instance of failure.

A gentleman in the theatre inquired the nature of the soil in the case alluded to.

Mr. Smith replied, both on a gravel and a clay soil. Many persons have asked whether or not the drains would be choked up in a rainy season. I have always asked them what position they referred to, and have opened it up that they may see; and in no instance have I found a single drain choked up. I have

the drains of 100 acres all discharged into one pond, provided for the purpose of seeing how much deposit came from the drain; and although we have had heavy rain, I have never seen the water in the pond tinged as if there was much soil in it. I can, therefore, safely recommend stone as a sufficient drainage; and in many parts of the country it is much cheaper than tiles.

The next filling need for preserving the opening of drains is the drain-tile. These are usually made of clay, and burnt. They are very handy and useful; and where stones are not to be had they are to be preferred. But there are districts where the clay-tile cannot be procured at any reasonable price. Lord James Hay has recently discovered a method of making them of concrete stones cemented by lime; in most instances they will come considerably cheaper than the brick-tile, and, if executed on the ground, where they will not have to be carried far, the breakage will be found to be very little, and they will prove to be durable. The cement made of lime is more lasting when covered than if exposed to the atmosphere.

There are two other modes of making drains—peat-earth has been cut into a shape somewhat like a hollow wedge; and a sort of instrument has been made for the purpose of cutting peat-earth into the form of the tile, so as to produce an opening not liable to the objection of the wedge, which frequently sinks and pulls up the opening. A stone is frequently used to lay the concrete tile upon, and prevent its sinking. It is also made of concrete.

Many persons have expressed the opinion that, in some of the very stiff clays, drains of this sort would not be efficacious, and that the application of the subsoil plough after the draining would have no good effect. With the view of showing the beneficial results, both of draining and subsoiling, I have brought some specimens of different clays, in order to show what improvement can be made. Here is a piece from the Pass of Stirling. This kind of soil has been cultivated from a subsoil, and has been known to produce excellent crops of Swedish turnips. Here is another very hard clay from Yorkshire.

A gentleman inquired how long after the subsoiling the land assumed a different character.

Mr. SMITH—Almost immediately—in the very first year. It requires some years before it becomes adapted for a turnip soil. I have a specimen of some soil which twenty years ago was so extremely stiff from the alluvial deposit in the Pass of Stirling, that it required to be broken with large mallets, to reduce, mechanically, the great lumps of soil. Thorough draining or subsoiling was never thought of till about twenty years ago, when this land was first drained; and now they get from it splendid crops of turnips, and in almost any season.

A gentleman wished to be informed of the nature of the soil in Mr. Smith's farm.

Mr. SMITH—It varies. In some parts it is sandy clay, and in others, clay perfectly impervious to water. When I first began to subsoil there was not more than three or four inches of active soil, properly so called, for growing plants; after a labor of about fifteen years I have now an active soil of sixteen inches, and can turn over that now in any part of the farm.

How near are the drains in order to produce that result?

Mr. SMITH—Twenty feet. I think a distance of about eighteen or twenty feet from drain to drain is a proper distance for almost any subsoil. I shall now proceed to detail the application of the subsoil plough.

When I began to cultivate my own farm, although I had put in the drains, I found they were not so efficacious as expected, and I then began to think of stirring up the subsoil, which gave rise to the idea of the subsoil plough. I thought I must construct an instrument which would exert the power of the water with the least possible power. I made my plough strong, and of that form to which the least resistance would be opposed, at the same time taking care to have sufficient power fairly to stir up the soil.

I will here explain the principle of the subsoil plough. The great principle is, that there are many subsoils, which, though capable of being converted into a good soil, yet if brought up and mixed with the active soil, will so far deteriorate it as to make it for some time sterile. The great point is to stir up the subsoil, still retaining the good soil on the surface. Stirring up the subsoil would, in the first place, very much facilitate the escape of the water into the drains; and in consequence of the passage of the water through the stirred up subsoil, and the attendant admission of air, it would be so acted upon as to be converted into good soil, while at the same time have all the advantages of working the active soil as before.

Upon the application of this principle, I have been successful in every instance. The process of applying the subsoil plough is this: a common plough goes along first, and removes a furrow of the active soil. After that the subsoil plough passes along below, and scarifies the subsoil to the depth of from twelve to sixteen inches, in some instances eighteen inches. This is continued furrow after furrow, the plough going first to lay the active soil on the part already opened up; then the plough comes a second time and takes off a furrow from another part of the soil, and places it on that which is already scarified.

As to the proper period for applying the subsoil plough in places where the drains have much effect, the subsoil plough may be applied the following year; but in clay soils it is important to give the clay sufficient time to dry, and to have it in a friable state; because, in the application of the subsoil plough, when the subsoil has been recently drained, and it is not sufficiently dry, more harm is done than good: the clay being worked in a wet state is almost prepared for making bricks. If we once work it in that state it is a long period before it recovers its friable property again. Therefore, in soils rather free, the subsoil plough may be used the second year after the drainage.

The proper time to execute drains is the summer season; you can then get it much more dully done, and the drains are prevented from running. In many places there are little sandy veins and portions of running sand, which are very apt to fall in before the drains are covered up. In the winter season this is almost sure to be so; you may be taken with frost, which draws off the adhesion of the earth, so that it falls down, and fills up the drain. It is best to execute them in grass land before it is broken up for cropping, otherwise it is too early. Executing it therefore in the summer season on the less produces very little loss, because the growth of the grass in the after part of the season will be so much increased by the execution of the drains, that you will be repaid for the time lost for the use of the pasture during the time the drains were in process of execution. After the drains have been completed, take a crop from the land, and if the land has been pretty good, it will, perhaps, afford two crops; at all events, one crop should be taken; that will pass over one summer before the subsoil is to be ploughed. During this season, the earth between the two surfaces has time to dry; it is more friable, and the subsoil plough will be more efficacious in stirring it up. It often happens that there are stones in the soil, which must be removed before you can proceed with good husbandry; and it will be found that, in consequence of the contraction of the soil, they have become in some degree loose, and will be turned out very easily by the subsoil plough. In many instances we have stones exceeding 200 lbs. weight, which are turned out very easily by the subsoil plough with four horses.

With regard to the direction in which the subsoiling ought to be carried, I should say at right angles with the drains; you thereby form channels, from the centre to the side, in all directions. In that manner you form artificial channels from the centre of the ridge into the drain; these may partially close up, still there is an openness given to the subsoil, which will permit the water to pass freely.

Having thus applied the subsoil plough to stir up the subsoil, the after cultivation may be the common rotation of the country, such as the farmer thinks suitable. When agriculturists have subsoiled their land, they should lay down the land to the surface, with the ridges and furrows, exactly on stiff land, a great part of the best of the land runs down into those furrows, and is deposited in large quantities at the bottom of the ridge, thereby doing a material mischief. If laid in a flat form you get rid of this evil, and obtain this advantage—that if the water is beneficial to the soil, which it certainly is, you have that benefit equally distributed; every part receives its own water, and the benefit which the water can give.

It is the suggestion of scientific gentlemen that the

rain in falling from the atmosphere absorbs a considerable quantity of ammonia; and if there is any of this in the soil for ammonia, if the soil wants ammonia, the affinity will extricate the ammonia from the water, the ammonia will extricate in the soil, and nourishment of plants. Where artificial manure is put into the soil, some of the fibrous parts of it will be carried away with the water, and be carried down to the region to which it belongs; and although not so near the surface as it was before, it is near enough for the plants to reach it when they put down their roots.

A peculiar change takes place in any subsoil—it does not matter what composed of—after it is ploughed. This change begins to take place immediately, and the soil gradually goes from the state in which it was before to that of a new soil. If you examine a soil which has become mould, it is of a peculiar structure. It appears as if all the particles were connected together, and it seems to have some attractive property by gathering together in that way. Vacuities for the air are thus formed, and there is a tendency to absorb and retain as much moisture as is useful to the plant. If filled entirely with moisture it is injurious to the plant, but if a certain quantity, becomes beneficial; and when a great depth of soil is attained, there is great advantage indeed, in either a wet or a dry season. In a wet season the water flows away, leaving the soil in a dry state; but in consequence of the mouldering state in which the soil is, it is retentive of moisture, and there is a great magazine of water preserved in soil for a dry season. Being covered by the active soil, the drought may penetrate a few inches, but in consequence of the lower part of the soil being covered with this upper stratum, it is defended from the extreme action of the rain, and a very dry atmosphere. It will be found that in soil so treated and converted into this mouldy condition, in dry seasons sufficient quantity of moisture will be retained for the use of the plants, which will grow vigorously when land in the same neighborhood is completely dry.

I do not think that it is possible to drain land too much, from the fact that the mould becomes an excellent magazine for the retention of moisture. A circular area took place in regard to this in my own district, in 1826, a very dry season. In that year there was so long a period of dry weather that the pond was dried up, and there was a great deficiency of crops. I had a field which had been trenched in the way I have explained, and I had a crop of hay on it. The hay in the country round produced not above half a crop. On this field, which I had ploughed to 16 inches, I had a splendid crop. A proprietor of land in the neighborhood, one of the old school, resisted to the utmost with regard to the result of thorough draining and subsoil ploughing. A person occasionally employed by me was also engaged in doing work for him. He had asked about this way, and thought the gentleman was rather puzzled at the state of the crop, and exclaimed that he really thought I had drained my land so much that I should have no crop at all. He was immediately after this completely weeded to the system, and from that day he has been vigorously engaged in introducing thorough draining and subsoiling all over his estate; and he is now having a great deal of poor soil, on a very rich and productive estate, treated in the same way. Taking the average of that gentleman's estate, he now produces double the quantity of corn that he used to obtain. He now grows potatoes where he could not grow them before, and on the old clay he produces regular and large crops of turnips.

An inquiry was made as to whether there was any land where subsoil-ploughing would be successful without thorough draining.

Mr. Smith—I am much obliged for that hint. Many persons have thought that ploughing the subsoil might do without thorough draining, but there are few instances indeed in which that application of the plough will not be hurtful instead of being beneficial. If you have a retentive bottom which will not allow the moisture to pass away, it must remain till absorbed by the atmosphere; therefore the greater the chambers for receiving rain, so much the longer will the land be kept in a wet state. The practice which now prevails in the English clay districts of ploughing with a shallow harrow has arisen from the experience of ages, which has taught them that on such soils you cannot cultivate wheat if you plough a deep furrow, because you make just so much the larger chambers to receive water. Even in open soils I would not recommend the application of the subsoil plough till the thorough draining had been executed.

A gentleman asked if it was necessary to repeat the subsoil ploughing?

Mr. Smith—It may not be essentially necessary to repeat the subsoil ploughing, but it is beneficial. I repeat the ploughing at every shift, every time I break up my fallow.

Is it always done in the same line?

Mr. Smith—Generally; sometimes I have done it obliquely.

Did you ever try it diagonally?

Mr. Smith—Yes; perhaps it is better to do it in that way according to the drop of the land. The first idea I had was to use the subsoil plough; then I thought I might use the trench plough, and that I might, the next shift, turn up the whole soil, so as to have a complete mixture. In some fields, where the soil was of a better quality, and there was more vegetable matter, I had excellent crops; on the poorer soils, I found that by bringing up the subsoil to mix with the active soil, after the first shift, I did a great deal of mischief. I found, especially with regard to grass, that I could not get that growth of plants which I had before; immediately on observing that, I resolved a third time to go over those fields, and that I would again use the subsoil plough; I have now fallen into the practice of doing so every time I turn. I took up at the first shift, perhaps about 3 inches, even in the poorest field; the next time 3 inches more; and by that means I gradually attained a thorough depth of soil to the extent of sixteen inches. On my own farm I have a thorough depth of sixteen inches, but that is in consequence of using a trench plough on the second shift; and in some fields that was unsuccessful. If I had had then the experience I now have, I would use the subsoil plough at each shift; instead of going down the whole sixteen inches, I would only take up perhaps three inches the first time and three the next, till I had completed the depth of sixteen inches.

A Gentleman—In draining in the summer season, how do you get the level?

Mr. Smith—By the spirit-level, of course.

A Gentleman—The great object would be to get it done cheap; but it would be much more expensive if done in the summer.

Mr. Smith—No doubt; but if I had the choice of executing drains during the winter, at an expense of 50 pence I should have them done in the summer, I would prefer doing it in summer. The efficiency is of far more importance than the expense.

In summer sometimes the land may be too hard?

Yes. In some places, but the bulk of the land will retain as much moisture as will enable you to get through it with the plough. Of course that will vary in different parts of the country. In some places it had better be done when the ground is more moist. Still, I would recommend it to be done, not in the winter, but in the spring or autumn.

A Gentleman—I may be perhaps allowed to say that there are cases where subsoil ploughing is effective without any drains; for instance, in the soils of the moorlands. I have tried it myself in the moorlands, and have found that by simply breaking up that pan which holds up the water, which made the lands dry in summer, and wet in winter, all the water escaped; and lands before not worth 5s. an acre, let for 20s. after it was done. That was certainly a peculiar case.

A gentleman inquired whether the rocks under the stratification were horizontal or perpendicular.

Mr. Smith—There was very little stratification at all. I am aware of what has been stated with regard to destroying the pans, such as are placed upon gravel; but, thorough draining may be applied with advantage to the soil, and that in a considerable distance, and consequently the water will be long in finding its way out, if it gets into the channel it will go off easily. Those dry soils retain moisture a great deal too long for agricultural purposes. A neighbor of mine was draining his land—a sort of irregular subsoil—and in some places had very considerable runs or rising ground with sandy and gravel bottom; he instructed his steward to stop the drain when he came to those holes. This was done, and two winters after the gentleman was coursing one day, and all at once his horse sunk over the fetlocks in the soft ground. He called out to his steward to know the cause, and his steward explained that this was the portion of land on which he had desired the drain to be stopped. This fact illustrates what I have said, that when agriculturists are determined on draining a field they should resolve to drain it wholly, otherwise they are only throwing the expense away. Where persons have drained wet parts, and left what they considered dry undrained, they have soon found that the land formerly the wettest was then driest, and when the part which had been drained was ready to receive the seed, they were de-

layed a few days till the other portion was sufficiently dry. In a country where we have much changeable weather, all agriculturists know the advantage of a single day. If a field is uniformly drained all over, you will, perhaps, be able to sow your seed one, two, three, or four days earlier than if it were not drained; sometimes you lose the opportunity altogether, because it frequently happens that two or three days intervene; very newly dried land will be ready for being sown, whereas other land, which was not drained, would require a week or fortnight before you could sow it.

With regard to the application of thorough draining on porous bottoms, no doubt much good will be effected without subsoil ploughing. I have found it most efficacious on sandy and gravel bottom. I have known instances of land of that nature being very greatly improved after being stirred up by the application of the subsoil plough.

A Gentleman—Your observation apply to thorough draining; many people call it *furrow* draining. I wish to know whether you have any reference to deep draining, and how, as in the case of a spring lying deep, you meet the difficulty occasioned by the water. Two feet and a half drains would not touch a spring such as that described on the diagram. How do you get away the spring water?

Mr. Smith—They are called furrow drains, because they are made in the furrows. I call the mode of doing thorough draining. I use the term to express the result. They are called sometimes wedge drains, top drains and tile drains; but the principle that you have the drains sufficiently close together to carry off the water quickly; and then, that the best mode of laying them off for that purpose is to arrange them in parallel lines, and carry them as much as possible in the sloping direction of the land.

With regard to springs, the spring water can do no harm till it enters the subsoil: so long as it keeps below that, you need not care about it. The moment it reaches the bottom of the drain, it finds its way into it, and will be carried off by it. I have found it necessary, sometimes, to carry a drain through the eye of the spring. Springs sometimes come in little channels, at other times in a sheet, according to the nature of the subsoil. When they come in a sheet, the cross-cutting completely sacrifices them. If a spring comes out a round opening and happens to fall in between two drains, I have found it necessary to cut the drain into the eye of the spring. But in every instance where the water flows between two beds, I have found that, by cutting the drain across, it was completely cut off.

I will now describe to you the mode of constructing the draining tile of Lord James Hay. One way of doing it is to construct the tile on the ground, and then carefully place it in the drain; the other is to execute it in the drain as you go along, and immediately to take it up. The composition of the tile may be varied considerably, but the proportions which I have found to do very well are—

Lime..... 1 part
Blackened cinders..... 64 part
Sharp fine sand..... 3 parts
Gravel..... 3 parts
making altogether 74 parts, or I measure of lime to 64 of sand and gravel: the cinders may either be used or not. The gravel selected should not be of a large size.

A question has been handed to me, as follows:—"What effect have thorough draining and subsoil ploughing on the habit of throwing out the wheat plant by frost?" It is well known to be owing to the fact that the wheat plant is thrown out, and whatever removes the moisture, will have the favorable tendency required. I have known many places where almost every winter the greater part of the plants were thrown out. Now, the result of thorough draining and subsoil ploughing is that they retain the plant perfectly well, and have very abundant crops.

The best of the two modes which I mentioned of forming the tiles, is to make them just where the drain is wanted, and in a few days they will become so dry that they can be placed in the drain. One disadvantage is, that these tiles will not stand carrying for a length of time. They require several months before they will admit of being laid one over another. But, in most instances, the making of the tiles can be accomplished on the spot, and in the course of a few days they may be put into the drain. It is, then, of great importance to cover them immediately with some light soil, free from stones, and to beat them down so as to preserve it from injury. If there are any stones in the soil, they may get down to the tile and seriously injure it.

[The lecturer then exhibited the method of form

ing the tiles in the drains, which is done by placing the mould in the place in the drain to be occupied by the tile, then laying upon it the concrete, and after pressure by an instrument similar to that used in the former process, drawing out the mould by means of a long handle attached to it for that purpose.]

I have an interesting communication to read from Scotland, which, though not immediately connected with the subject before us, bears intimately upon it. There are great doubts respecting the propriety of putting seed deep into the soil, or covering it very lightly. Experiments have been made on that subject, but none so conclusively as that which I have now before me, which relates to the springing up of the more tender seeds, the grass seeds; and it shows the great importance of having a shallow covering over them. This experiment was made by the Messrs. Drummond of Stirling, the individuals who first introduced the agricultural museum.

This experiment tends to show the great importance of a light covering to grass seeds. I have made a barrow of a peculiar construction, which reduces the surface soil very much without tearing up the ground. It has no teeth, but acts by little sharp discs, closely set together, which curve very slightly. I have found this instrument also very efficacious if used as a bush barrow.

Continuation of Mr. Smith's Lecture.

The report of Mr. Smith's Lecture was given from the Mark Lane express, which did not contain the diagrams to which Mr. Smith is reported to have referred when lecturing. After that report was in type we received a second copy of the Lecture in the London Farmer's Magazine, with the diagrams. For the gratification of our readers we subjoin these diagrams with the accompanying explanations. Though not in their original position, they will not be found out of place; and the more report of this lecture to any intelligent farmer, is worth ten times the annual subscription of our paper.

I shall first endeavor to illustrate by a diagram, the mode in which this system of drainage operates.

A represents the atmosphere, B the active soil, and C the subsoil stirred by the plough; D represents the part of the subsoil above the level of the drain. When the ground has been so drained, the first effect that takes place is the drying of the subsoil, which begins generally at the drain, however close and dense it may have been; it begins to crack there by the water giving way. These cracks are continued till they pervade more or less; and in the course of a few months, or perhaps a couple of years, they may have obtained complete effect; the whole of the soil has become dry. The soil which has been worked before on the surface of the subsoil, is in an open state from its former working; the rain falls on the earth, and is received into the intervening spaces, the chambers all receiving so much rain, and the different parts of the soil absorbing a quantity of rain. But while the rain is falling, the drains are carrying off the water from the whole mass. Of course when the rain ceases to fall, this water goes off more rapidly. At first it will be brim full (if I may use the expression) of water; it is constantly running off, and the water gradually subsides.

The usual practice is to make the drain two feet deep, but I prefer two feet six inches, for this reason, that it is of the greatest importance that the whole subsoil flow off as rapidly as possible. Persons are apt to suppose that the water will not find its way to a drain at a great depth, but that is in some measure a great mistake. When there is more water to pass through, there is more retardation to the passing of the soil; but, notwithstanding, by giving the drain the inclination which I propose, you have the water carried off much faster. There is also this advantage—that when there has been a long season of dry weather, the whole of the bench becomes completely dry; and in that case it takes much rain to wet it, and if the rain is not very abundant, perhaps the water will not stand higher than B. When water falls upon the soil, there is one very great advantage in having a large bench besides. There is a quantity of air which fills all the vacancies in the soils—the active

soil itself, the stirred subsoil, and the subsoil which has been laid dry. When the water has drained off, air takes its place, and the action of the air is very beneficial on the whole of the soil moved, particularly the active soil; and just in proportion as you have a great area to receive the water, and to receive air as the water is drawn off, so in proportion you have a tide of atmospheric air passing through the bed of active soil which is found very much to improve it. We know this soil is very much improved by exposure to the atmosphere; but if it improves in a greater degree by exposure to the sun and light, it is still importantly improved by the passage of the air to the lower strata when the water is withdrawn.

In order to render a field completely dry, it is necessary that a great number of drains should be placed in it; and the position in which they should be arranged will be obvious from this diagram, which represents a field sloping down, with a rising ground in the centre, and rising ground towards the side.

This is made for the purpose of illustrating the mode of laying off drains, and the mode of catching the water when any hollows intervene. In laying off the drains, you will drain the field more effectually by laying them off in parallel lines, than by doing it in any other form: because, if you depart from the parallel lines, you get into corners, and into some spaces not so near the drain, and others too far from it. But in laying it off in the manner shown in the diagram, you get a complete effect on the whole surface. When drains are laid off to run in the direction down the slope, they have a much greater effect in draining than when laid across the field. It is rather difficult to induce persons to believe this, but it is the fact. If carried across the field, though they may catch the water, yet, having less declivity it will remain longer at the bottom of the drains. Another objection is, that the water which is there retained, has a tendency to sink away to the sides of the drain, and therefore will probably come up some distance below the drain. But if the drains are carried in the direction pointed out, you cut the drain so that the water constantly sinks into it; and though it may fall a little into the slope of the hill, yet the greater part of it goes to the drain.

[Sections of the several kinds of drains referred to.]

Paste for Sharpening Razors.

Take oxide of iron levigated, vulgarly called prepared putty, one ounce; saturated solution of oxalic acid, a sufficient quantity to form a paste. The composition is to be rubbed over the sloop, and when dry a little water or neat's foot oil is to be added. The oxalic acid having a great attraction for iron, a little friction with this powder gives a fine edge to the razor.—Eng. Pub.

Important Notice.

There is a large amount due us from Post Masters and Agents in the Western States and elsewhere, mostly in small sums it is true, but our whole resources depend on such small sums, and therefore we hope no one will delay sending on that account.

One word to our friends.—We have a large supply of book numbers of the current volume on hand, which ought to be in the hands of subscribers. Will you not help us—would you not be doing your neighbors as well as ourselves a real kindness, by soliciting them to subscribe? The currency is now considerably improved, and bills of most of the states will answer for remittances. —PUBLISHERS.

Salt for the Grub Worm.

Mr. COLMAN—In examining a neighbor's field of corn, I perceived some of it cut off by the grub worms, and deemed it best to examine my own. To my surprise I found they had been destroying my own at a great rate; and had made their way into the garden and were engaged in cutting off the cabbages at the rate of four or five every night. It appeared that they did not touch them by day; and when I went out in the morning I found my cabbages gnawed off close to the ground. I first applied ashes to the hill, but without effect; then soil, but it was like the wind and did not affect them. Scotch snuff was then recommended to me, but it availed nothing against them. The June number of the New Genesee Farmer, however, arrived about this time, in which it was stated that salt was so disagreeable to the grub that it would effectually protect the corn and cabbages. I had tried every other preventive which I could hear of, and determined to make an experiment with salt. I applied, therefore, about two table spoonful of salt to each hill of corn or cabbage, and laid it so as not to touch the stalk or plant. Not one has been molested by the worms since, though they have begun to eat the weeds in the vicinity, to which I do not make any strong objection.

I send you this statement for the benefit of farmers. From a three years subscriber.

Yours truly,

R. H. Jr.

East Bloomfield, Aug. 6, 1842.

We are much obliged to our correspondent for the above communication, and should be glad to hear from him, as he suggests we may do, on other subjects. The observations of plain practical men are of great value; and it is by the accumulation of such well established facts as these that we may arrive at the most important and practical conclusions. The application of so large a quantity as two table spoonful of salt is probably much more than would be effectual; but this can only be determined by repeated experiments. The salt in such case, beyond the destruction of the insect, is probably not lost, but its benefits may be felt in succeeding crops. As we have before said, we mean to go fully into the subject of salt as a manure at a future time—a present, however, we throw out only one or two suggestions.

Land in the vicinity of the sea, where sea-weed and sea-weed are easily obtained, are, with few exceptions, essentially benefited by the application of sea-weed, rock-weed and kelp, either simply spread upon the grass land or spread and ploughed under. Much of the benefit in these cases is supposed to be due to the salt with which these grasses are impregnated. We have often applied them with the most decided advantages. One of the best farmers of New England, living near the sea, assured us that he estimated the value of salt hay, that is, hay cut upon lands customarily flooded by the tides of the ocean, as equal to five dollars per ton as a top-dressing for his grass land. We have known, likewise, upon six acres of land, dressed chiefly and most liberally with rock-weed, gathered on the sea shore, a crop of upwards of twenty-nine tons of hay, weighed, when well cured, at the town scales, to be taken in one year; and we have been familiar for years with a field of about forty acres, annually manured with rock-weed, kelp and sea-weed, where the ordinary yield was estimated at 120 tons upon the forty acres; and as this hay was almost wholly carried to the market, there could be no essential mistake in the estimate.

These facts present the subject of experiments with salt as a manure as matter of great importance; and as the cattle in the interior, remote from the sea influences and atmosphere, require frequently this condiment or seasoning of their food to be given to them, may it not be inferred from analogy, that lands remote from the sea may be in some degree deficient in this

element of fertility, and receive an equal benefit from its application?

The use of salt as a manure is not new at all; but while it has been fully settled that a certain amount is almost invariably beneficial, any excess is directly pernicious. To determine the safe medium is greatly to be desired, and can only be ascertained by repeated experiments judiciously made; and in which all the circumstances are carefully noted.—*Ed.*

Salt for the Grub Worm.

Since sending to the press the communication of R. H. Jr., on salt as a protection against the grub worm, we have received the subjoined, confirmatory of the foregoing, which we have much pleasure in inserting, and beg that we may again and often hear from our correspondent.—*Ed.*

EXTRACT.—*London, Canada, 15th August, 1842.*

I should be glad, through your columns, to thank the individual for his article on applying salt to plants to kill the grub, (not the gentleman who recommended a table spoonful to each plant, but the one who applied it to the plants at the rate of a bushel to the acre). Previous to reading this article, I had tried several things and had planted over and over again and again, but my plants were as quickly destroyed, and I was about to give it up as a failure when your number came to hand and I saw the article on salt. I immediately put about a pinch to each plant, which I repeated a second time, and I had no more grubs. We had, however, at this time moist weather.

On mentioning this remedy to a friend, he said he could not account for a fact, which before had to him appeared a mystery. It was this, when he set out his plants (cabbage) he watered them with water from a salt-pork barrel daily, for about a fortnight, during which he had no grubs; but thinking the cabbage plants had sufficient root, he discontinued, and soon after he found the grub attack his plants as much as his neighbors. The salt in season enabled me to have cabbages in season; and should I receive no other benefit from the perusal of your N. G. Farmer than this simple cure, I shall consider my half-dollar well laid out.

X FARMER.

Rust in Wheat.—Rusted Straw for Cattle; an Inquiry.

We hear many complaints from different parts of the country of injury to the wheat from rust, and of short and imperfectly filled heads. These complaints are not extraordinary; but they are not wholly without foundation. Yet there is ample reason to think that the crop of wheat throughout the country is unusually large and fair.

The inquiry of our correspondent in relation to the effects of giving rusted straw to cattle, are very important. We request the particular attention of experienced farmers to them, and beg that we may hear from them on the subject at an early date. For ourselves, we have used it to some small extent, but always with great misgivings, though with no ascertained injurious results; in these cases, however, we never used it alone without hay; and always felt that the litter yard was a much more proper place for it than the crib.—*Ed.*

Mr. EDITOR—The wheat in Tompkins county has probably suffered more from the effects of the rust this season, than any other county in the state; consequently the produce will be considerably diminished. It is confidently believed by many that it will fall 50 per cent below an average crop.

In some sections the yield is above an average one, and the berry very plump and fine; while perhaps in districts two miles distant, the failure is only partial,—three miles, there are instances of a total failure.

As is customary with us, and with farmers in all places, many feed much of their wheat straw to their cattle; but this season, the straw is so much rusted that

some are apprehensive that disease may be produced if diseased straw is fed to them—instances being known, it is said, of its having proved fatal.

I am informed, indirectly, by Judge — of this county, that some years since, he lost all his stock, and many cattle of his neighbors also suffered much, in consequence, he believes, of feeding rusty straw.

Judge — is known among us as a man of much discernment and discrimination, and I have never known his integrity questioned. I will endeavor to prove his statement of the matter, and will forward it for publication; therefore, you need not receive it as "all talk and no cider." Do you or any of your correspondents know these things to be so; if you or they can speak affirmatively, please inform us.

CHARLIE.

Agricultural Intelligence.

THE NEW YORK STATE AGRICULTURAL SOCIETY holds its annual Show at Albany, on the 27th, 28th, 29th and 30th of September. It is designed to be a great occasion for the farmers. Two thousand dollars are to be distributed in premiums; and the competition we have no doubt, on public as well as pecuniary grounds, will be the most extensive and spirited that has ever taken place in the country. No pains will be spared to render the occasion worthy of the State. Better than all other things, it will bring together many of the most intelligent and best friends of agriculture throughout the State and the United States, on an occasion where no party and sectarian interests can disturb the festivities; where they may stimulate and assist each other in their best of all improvements; where reflecting minds will have occasion to contemplate with the highest sentiments of religious gratitude the beneficence of the Creator in his abundant provision for the sustenance and comfort of his creatures; and find stronger and stronger motives to make this provision yet more abundant, that the comforts of life may be so widely extended in our fertile and free country, that not one of his great family shall be sent empty away from the table of his infinite bounty.

The Trial of Agricultural Implements will be on Tuesday, the 27th. The General Exhibition on Wednesday and Thursday, the 28th and 29th. The public sale of stock, &c., on Friday, the 30th.

Farmers desiring to contend for the premiums are reminded that the regulations are absolute, and will be strictly adhered to.

Cattle Shows, Fairs, and Ploughing Matches.

We subjoin a notice of the times of holding the several Agricultural Fairs, which come within our knowledge, within the district where our paper principally circulates, and shall keep it in until the times arrive. We shall be obliged to the Secretaries of the different Agricultural Societies in New York, Ohio, New England and Canada, if they will give us (post paid) the notices of their respective fairs.

Northumberland, Grafton, Oct. 12th

Gray's Elements of Scientific and Practical Agriculture.

This compend is designed to supply a great desideratum among agriculturists. It has been compiled from all the important works on the subject which have appeared in the last few years. Its object is to exhibit the principles of agriculture, and to set before the farmer the chemical and philosophical reasons for many operations with which the practical farmer is familiar. It presents at the same time many new principles and reasons on the business of agriculture. It is the pointing up of the discoveries and elements and details of this first of arts and sciences to the present day. It is not a servile copy of any work, though it pretends to little originality. It embodies and carries out the grand principles of Liebig, perhaps the most distinguished of all the scientific agriculturists of the day. "Agriculture, say aye, is the true foundation of all trade and industry—it is the foundation of the riches of states. But a rational system of a riculture can not be formed without the application of scientific principles." The nature of soils, the influence of manures, the composition of vegetables and the laws of vegetable life, the changes produced by cultivation upon the soil, the most economical means of preserving the heart of a farm or field, and the reasons of the wasting influence of some plants and some modes of cultivation—all these need to be well understood. The great progress in this knowledge has been the result of the advancement of chemical knowledge and its application to practical agriculture. A great amount of this knowledge is contained in Mr. Gray's work, and presented in a form attractive, while it is scientific, minute and clear. The work indeed must be read and pondered; it must be studied, and made familiar. It is a dishonor cast upon agriculture, to suppose that its principles or practice are too free or simple or obvious, to require much thought, study, effort or wisdom. Where the larger works of Johnston, Liebig, &c., are not possessed by the farmer, the work of Mr. Gray will be a great addition, and not be out of place even with those.

Mr. Gray maintains, in opposition to the conclusion of Liebig, that plants do not derive all their carbon from the atmosphere through the absorption of carbonic acid gas. Mr. Gray's reasoning seems to be decisive.

It was the doctrine of chemistry thirty or more years ago, that the animal and vegetable kingdoms mutually minister to each other, and that the carbonic acid thrown by the respiration of animals, combustion, &c., into the atmosphere, was removed by the vegetable world, and that this is the grand instrument of purifying the atmosphere and continuing its purity. This is no doubt the fact. To maintain this grand principle, it is not necessary, however, to suppose that the atmosphere is the only source, though it may be a great one, of carbonic acid, the great pabulum of vegetable life.

Following great men, the author has given some particulars, utterly incomprehensible. Thus he says, p. 39, "The most correct definition of life is given by Bichet, and modified by Whewell. 'Life is the system of vital functions.' No man can attach a meaning to this definition. Does not the system, in which the vital powers acted, remain after death, till organic changes take place? Then life is not the system. Or, does he mean by 'system of vital functions,' only the totality of vital operation? Then life is life; the great wisdom in the definition. The truth is, as long ago said, we know what life does, not what life is; we define it by its operations, and not by its nature or essence, for of this we are ignorant. We are sorry to see any such philosophical abstractions. We are glad they are so few.

In some cases it is very doubtful whether the true philosophy has been given. The mistake is of little consequence, because on the right or wrong principle, the practice will be the same. Thus, the chief use of gypsum is maintained by Liebig to be in condensing ammonia or other elements, so that they may be conveyed into the plant. Now it is far more probable that a small portion of gypsum, potash, phosphate of lime, &c., is necessary for the full development of the plant. The organic elements are four, oxygen, hydrogen, carbon and nitrogen; the inorganic are, besides gypsum and the others just mentioned, silica, soda, magnesia, iron, &c. The latter are supposed to be as important as the other to the healthful and powerful action of vegetable life. To a certain extent these may be food and stimulus to vegetables. They may be far more important than to be the mere vehicles of transmitting other substances; and such a principle is far more consistent with the economy of the laws of matter.

Phosphate of lime is essential to the formation of bones in man and beast. In the growth of the young it is rapidly deposited; and in the older, it is necessary for a new deposit to replace that part of the bone which is removed on account of its being worn out. How beautiful that economy which supplies through the food the constant demand for this substance. In the mammiferous tribe, the very milk of the mother conveys this element of healthy growth and action. Small as is the quantity in any article of food, it is constantly posing in adequate supply, removed from the soil by vegetables, and by animal and vegetable substances returned to the earth, again to perform its wonderful work.

Plants take from the soil those substances which are necessary for their healthy action. In time, these must be exhausted, if the vegetable growth be removed, and if they are not returned by manures. For the growth of any one plant, the best manure must be the plant itself, because it restores the elements removed. Thus the straw of wheat would afford the best manure for wheat; the tops of potatoe, for that plant; of corn, for corn. This is the lesson taught us by providence in the natural production of plants. This doctrine is insisted on by Liebig, and maintained by Gray. It may be called the *first element* of scientific agriculture.

The second element is the adapting the plant to the kind of soil, or the kind of soil to the plant. This opens before us the broad field of science and practice in agriculture. In the examination of this field, the work of Gray will be highly interesting and useful. We cannot enter upon the details, but we trust the farmer will examine them for himself, for he cannot fail to be amply repaid. C. D.

Fermented Vegetable Manure.

A new method of making *Vegetable Manure* by Fermentation has recently been patented and brought before the agricultural public, by Mr. G. Bommer. Farmers and gardeners have an opportunity of seeing a heap of buckwheat straw under the process in the yard of Mr. Bachmeyer, 119 West Market street, in this city. Mr. B. is the agent of the patentee for this and several of the adjacent counties. By means of his method, it is said, every farmer may reduce his straw, refuse hay, corn stalks, and all other vegetable matter, to rich, unctuous manure, within 15 days, and at very little cost. The preparation is very simple and easy.

This Manure is a composition of animal, mineral, and vegetable substances, and may be made at any season. A compost may also be made with common earth, where straw and other vegetable matter is wanted, which will answer all the purposes of animal manure, and prove a superior substitute for lime, plaster, ashes, &c. The process produces nitrate of lime, potash, ammonia, and saltpetre, four of the most fertilizing properties of good manure. Among those who have tried it with success we notice the name of Mr. J. W. POINIER, of Morristown, and Mr. Pierre Grey, of Madison, whose testimony we subjoin:

"Mr. Bommer has publicly made use of our premises his Vegetable Manure. The result of his process has been entirely satisfactory to me and those of my neighbors who have witnessed the operation, and examined the product.

"The materials made use of in that experiment were straw from my barn, made into a heap on the 5th of May last, and opened a fortnight afterwards. At that time the straw was found altogether decomposed, and changed into a dark Manure, very unctuous and rich, having a strong smell of ammonia, and of good litter.

"And I hereby further certify that this Manure has been used on a field of Turnips, in which it had an excellent effect, and also in my garden, where I obtained superior vegetables, among them some pumpkins of an extraordinary size for the kind, as may be seen at my house. PIERRE GREY."

The Newark (Conn.) Gazette of the 12th inst., speaks of a successful experiment, in that place, with *Sedge*, a coarse grass which grows about the flats of the harbor, mixed with sea-weed. Those of our readers who are interested in the cultivation of the soil would doubtless be gratified to see the heap now fermenting in Mr. Bachmeyer's yard.

The cost of this method is inconsiderable. Cleared land, intended for agricultural purposes, (wood land excepted,) under 50 acres \$10; more than 50, ten cents per acre additional. On payment of this sum, the method becomes the property of the purchaser for ever.—*Newark Sentinel*.

Lightning Rods.

I wish every farmer would from this time forth, keep a register of all the accidents from lightning which he sees in the newspapers—the deaths from the striking of dwelling houses, the well filled barns laid in ashes, &c., and if he is not then protected by a rod before the summer of another year, it must be from the spirit of procrastination. What is the cost and labor of erecting one, contrasted with the feeling of security,

"When o'er heaven's rending arch the rattling thunder rolls—"

What is the cost and labor of erecting one? Four dollars—not often more. The writer lately put one up on a building 23 feet high—the whole length of the rod was 42 feet, so that 12 feet projected above the building, and it descended 7 feet into the earth. The iron cost less than two dollars—the blacksmith work was a dollar, which I thought too much; and digging the hole and erecting it cost about fifty cents; making only three and a half dollars in all. The part below the roof need not be large,—not more than five-eighths of an inch; the part above should be of three or four pieces of successive sizes from one inch to half an inch, welded together, so as to form a somewhat conical piece, to stand firmly in the wind.

The height above the roof should be one half the length of the building if placed at one end, or one quarter the length if placed in the middle. It should be continuous throughout—not *linked*—but the joints welded together; and it should descend into permanently moist earth, which is not often found at a less depth than six feet. It may be kept to its place by small pieces of plank, with holes bored through to admit the rod, and these nailed to the house so as to keep the rod several inches off.

The points, which should be several in number, may be made of small iron rods welded together, and to the rod, filed sharp, and polished. Tinning them might be an advantage. When one point only terminates the rod, it is not always sufficient to carry off silently the load from a heavily charged cloud, hence an explosion follows, which in one instance familiar to the writer, melted the point of the rod into a ball, but without any injury to the house or its inmates, though the noise of heavy artillery was a mere pop-gun to it.

If lightning ever struck a building protected by a rod made as here suggested, or according to its leading principles, I have not heard of it. Q. E. D.

REELING SILK.

The unwinding of the silken cocoon is performed upon principles of surprising simplicity, yet the popular fallacy regarding its insurmountable difficulties has accomplished more to retard the culture of silk in the United States, than any adverse cause whatever. The writer was early impressed with the prevailing prejudice, but the first ray of intelligence was sufficient to dispel it. The first attempts were sufficient to reveal the truth, that this was the simplest division of labor connected with the art of raising silk.

Before entering upon a particular description of this art, it is proper to apprise the reader of the nature of the instrument by which it is accomplished. The standard silk reel of Europe is the Piedmontese reel, and all others combine its principles, which are these. If we attach to the bars of a common reel, the fibres of several cocoons and direct the combined thread so that it shall in every revolution fall in the same place, the consequence will be that in drying, the component threads of the skein will be glued together and cannot be unwound. This is why the common domestic reel is inadmissible. The Italian reel obviates the difficulty. It is so contrived that the guides that hold and direct the thread, shall slowly vibrate, by which movement the thread is laid, not at right angles with the axis of the reel, nor upon the same place as the turn which last preceded it. The threads are laid parallel to, and at a little distance from each other, and when they have travelled over the breadth of the skein they are directly carried back again, so that each alternate course crosses the other at a sharp angle. This movement allows the thread time to dry, and by the crossing of them adhesions are effectually prevented. It is somewhat in imitation of the instinctive method of the worm which never lays the threads in parallel contact, but by a sweeping motion from side to side.

The silk reel contains two sets of guides, one for gathering the fibres of the several cocoons into a compound thread which are stationary, and the other just alluded to, for guiding the thread upon the reel, and is of course moveable. Under the first set, is a basin resting upon a furnace which heats it. The reeler sits behind this basin, and she requires an assistant to turn the reel and to perform other services in her behalf.

No other than water perfectly soft and pure will answer, and its temperature must always be below the boiling point, but generally very near it, and it must never be suffered to become foul. Before the reeler commences she must classify the cocoons, by separating the double ones into one parcel and the indifferent ones into another, collecting the excellent ones by themselves. She must be careful not to mix up parcels whose chrysalises have been destroyed by different methods, for each will require modification of temperature. She must remove the loose floss and settle in her mind the size of the thread she is to form. If it be a thread of ten fibres, it will require eight to twelve cocoons, for as they run out the filaments become smaller. If it be a thread of twenty-five fibres it will require from twenty to thirty, which is the size easiest maintained, and is about the proper size for present demand. The novice had better commence with unstuffed cocoons, for they play off with greater freedom than those containing dead chrysalises.

She takes her station, and throwing into the basin a few handfuls of cocoons, she presses them gently under the surface of the water with a brush composed of three or four sticks of broom corn, or a little bundle of fine twigs, until the ends of the filaments have become entangled with them, when she seizes them with the left hand and laying aside the brush, she draws out the threads, hand over hand, until they run free, when they should be fastened aside until all the threads are thus gathered up, and it is important that no more

come or put into the basin than are necessary for immediate purposes, for it creates confusion and waste.

She then takes a sufficient number of fibres to form two separate threads, which are at once passed through the lower guides, where they are twisted over each other twenty times, more or less, for the purpose of consolidating and rounding them and dissipating moisture, the greatest care being taken to keep each division distinct. Each combined thread is next passed through its second guide and attached to the bars of the reel. If the water be of proper temperature, the reel may be turned with a quick movement, which immediately brings out the gossamer outline of the skein, beautiful to behold.

After the reel has been turned some time, the threads will diminish in size, some of the cocoons having broken and some run out. This is prevented by constantly attaching new fibres as others become exhausted, and it must be done too without stopping the reel, by gently touching the end of a fibre to the thread just as it passes the lower guide.* This is an operation that requires some tact, but it is easily acquired. When the capsule of the chrysalis is laid bare, it must be removed with a small skimmer, and new cocoons constantly added, few at a time. Every particle of silk should be extracted from the cocoon, which is impossible if too many are playing at one time.

This is the simple line of the reeler's duty, and to perform it well she must observe some collateral directions. She must be patient and reel without waste, and that in the most finished manner without regard to quantity, for that will depend upon practice. Her progress will be slow at first, but she will inevitably acquire adroitness. The nature of the process will soon unfold itself, and she will throw aside her written directions. She will perceive that if the water be too hot the silk will come off in masses or buns, which will break the threads or injure their beauty. If it be too cold the gum of the cocoon will not be sufficiently dissolved, and it will fly up to the guides and break the thread, or leap out of the basin. If bus should be discovered upon the skein, they are to be removed by the assistant before they become dry, and it is her duty to watch the skein and the course of the threads from the guides to the bars, that every thing runs free and smooth. When the reel has been a little time at rest, the threads must be wet before starting from the guides to the basin, or the threads would lose their adhesion, and being dry would break at the guides. The skeins should not be disturbed from the reel until perfectly dry, and this is done by starting the keys in the axis of the reel.

The reeler's duty is one of constant activity, and requires quickness of motion and adroitness of touch, natural ingenuity, composure of mind and a determined spirit to succeed. She will be astonished at the result of her exertions. Understanding the principles of the art, the details will suggest themselves to her mind, and she will in a short time turn off one or two pounds of silk daily without the least difficulty. It is certainly a beautiful operation that may well engage the attention of young women, for they will find it an independent, honorable and profitable employment. J. D.

Manufacture of Silk in Ohio.

Mr. John W. Gill, of Mount Pleasant, Hamilton Co., Ohio, manufactured during the last year upwards of \$9000 worth of Silk goods. His clear profit on the capital invested was ten per cent. He has three large conneries and commenced this season to feed upwards of two millions of worms, he calculates, will yield him upwards of six hundred bushels of cocoons, worth at present prices \$2000, but much more to him, as he will manufacture the whole crop into various fabrics.

* This guide should be made of a plate of brass, by drilling a fine hole near its upper edge and sawing a slit to it, the upper extremity opening like the letter V, and made perfectly smooth.

Botany.—The Active Female Accomplishments, versus, External Show.

M. de Candolle, Professor of Botany at Geneva, while exhibiting at his lectures a very valuable collection of American plants, took occasion to say to his audience that this collection was borrowed, and must be returned by a given day, much to his regret. Some ladies present immediately offered to copy the whole collection by the aid of their friends in one week, and the task was faithfully performed. The drawings, 860 in number, filling 13 folio volumes, were executed by 114 female amateurs in less than six days. The principal part of each plant was colored, the rest traced with accuracy,—the execution was invariably good, and in some instances masterly. It is said that this taste for the arts and for knowledge in general, is universal in that city.

Once travelled on a canal boat in company with a young Swiss botanist, who was educated at Geneva; his whole soul seemed filled with the grandeur and beauty of our vegetable creation; he would often leave the boat an hour at a time to walk ahead and collect specimens of plants and flowers, these he would bring on board to arrange and press in his herbarium. We had several village young ladies, passengers, going west on a visit; they were lively girls, very expensively and tawdrily dressed; but they loved art better than nature; in fact, they had no taste for the glories of the vegetable world; hence they looked upon our foreign Botanist who could not speak English, as they would upon a wild animal whose genius was inferior to their own. But to show that his opinion of them was not more exalted, than their estimate of him; when I asked him what he felt to be the principal difference between these American young ladies, and those of his own country, he quietly replied, "*celles ci sont des poupées, celles là, des anges*," these here are dolls, there they are angels. This young man had been but two weeks in the United States, but who will say that his first impression in relation to our American young ladies was wide of the mark. He only meant to convey the idea that in his own country the intellectual pleasures are cultivated, instead of those senseless, expensive, fashionable, and demoralizing habits of external show, so universal in these United States. S. W.

Watertown, Aug., 1842.

Songs of Birds.

It is quite amusing as well as of real utility, assisting as it does the memory to distinguish the songs of various species of birds, and thus enabling the observer readily to identify them,—it is quite amusing to observe the translations into English of their various ditties. Nuttall gives on the authority of the New England boys, the following as the Bob-o-link's song: "Bob-o-link! Tom Denny! come pay me the two and sixpence you've owed me more than a year and a half ago, go, it's clear, it's clear!" A tailor observed to me that the song sparrow continued to prate round his window, "Prick your f-i-n-g-er, suck it, suck it well!" The iron-founder rendered the robin's song into "Skillet! skillet! two legs to a skillet, three legs to a skillet!" and a well known physician in Y—remarked that the same bird often gave him this admonition: "Kill 'em, kill 'em, cure 'em, cure 'em, give 'em physic, physic, physic!" Even the frog speaks English (or rather Irish) as, "Jug o' rum! jug o' rum! jug o' d-run!?" or, "Paddy got d-run, got d-run, got d-run, 'unk, 'nk!" X. Y. Z.

Tar for Wheels.

A friend informs me that the use of tar in the Eastern States for waggons and coaches is now, or soon will be entirely superseded by the introduction of boge lard and wheat flour. To prepare the mixture, the lard must be melted over a gentle fire and flour stirred in until the lard becomes of the consistence of a paste. Our friend warrants us in advising farmers and waggoneers to adopt the plan. He says they will never use tar afterwards.—*Local Standard.*

ROCHESTER, SEPTEMBER, 1842.

Agricultural Excursion in the Genesee Valley Continued.

(Account of Crops continued.)

BUCKWHEAT is raised to some extent, but largely. I could not learn that in any case it had been used as a green-dressing to be ploughed in, a process not unknown in some parts of the country, and from which I believe much benefit may be derived. The cost of the seed is a small affair; and the preference of such management over a naked fallow can hardly admit of a doubt. A few careful experiments in this case would decide an important question.

GRASSES.—The Grasses cultivated are the red-clover and Timothy or Herd Grass. The meadows or alluvions on the Genesee river abound in rich natural grasses, and are peculiarly favorable to the growth of grass.

In one or two cases, on a small scale, I found the orchard grass cultivated; but merely as an experiment; and I met with two small fields or rather patches of millet, sown probably for the same reason. The stalk was extremely large, which indicated, in my opinion, too thin sowing; certainly, if it were intended that it should be cut for hay. This is a common error. The allowance, with most farmers, of seed for a crop of millet is one peck per acre. If the land is rich, the stalk in such case becomes as large as brush; but where a bushel is sown to an acre, the stalk is small and fine, and the hay, when well cured, of the very best description. I have myself obtained three tons to an acre, weighed, after being well cured, at the public sale.

Of grasses, clover is extensively cultivated. It is sown on the wheat in the spring at the rate of 7 or 8 pounds to the acre. It is commonly depastured in the fall, and the field is allowed to continue in clover the ensuing year, and the succeeding spring is ploughed and fallowed for wheat. In other cases it is depastured in the fall of the year in which it is sowed; and in the ensuing spring the land is ploughed and fallowed for wheat.

There may be said to be three distinct kinds of clover customarily sowed by the farmers; the first is the June or Southern clover; this is comparatively small and ripens early; the next is the Northern or Vermont clover, which ripens late and grows with great luxuriance; the third is the Ohio clover, which holds a medium character between the two. I found that both for hay or for ploughing in with the stubble, farmers differed in their choice, preferring either the Southern or the Ohio clover. The Southern clover makes the best hay and is more easily cured than either of the others. The Northern clover makes a very coarse hay.

The crop in general averages from two to three tons. The opinion of many of the best practical farmers, whom I consulted, is decidedly in favor of curing it mainly by sweltering in the cock. In this case it is cut but not spread, and after lying in swarth until it becomes entirely dry from extraneous wet and slightly wilted, it is put into small cocks and suffered so to remain until it becomes *made*, which can only be determined by good judgment and experience. The cocks are then turned directly upside down, until the dampness gathered at the bottom of the cock is wholly dried off, and are then carried into the barn. I have known this same method practised by some of the best

farmers in Massachusetts, and in other parts of New York; and the hay under such circumstances retains its sweetness and color, the flowers and leaves are not shaken off and lost, as when the grass is much tossed about and spread; and the hay proves of an excellent quality.

Timothy or Herd Grass cannot be said to be cultivated extensively, though I think some of the finest fields of Herd grass which I have ever seen, I found on Mr. Le Roy's place near Avon, on the opposite side of the river. I hardly know what could be more luxuriant, even and beautiful. On the Genesee flats above in the great valley, the hay was most abundant, but as I have remarked of a more mixed character. Mr. Wadsworth is accustomed to feed or depasture some of his fields so late in the spring that the crop of grass is not fit to be cut until the season is far advanced. This divides and extends his time of haying, as the different fields ripen in succession, and his haying season reaches into September. This late-grown hay is, I presume, not so substantial and nutritious as an earlier crop would be, partaking very much of the character of roven, but this is compensated by the advantages of the feed in the spring. The practice of taking two crops does not, that I could learn, prevail here; and this I believe from an oppressive feeling of abundance rather than that it might not in many cases be done to advantage, for with respect to many of the farmers of this rich section of country, the case must be as with a farmer mentioned in another place, who needed to pull down his barns and build greater, that he might have where to bestow all his goods.

It is difficult to estimate with any great exactness the ordinary yield of these best lands in grass, but it may be safely put down as averaging over two tons per acre. I do not know where finer crops are to be found, and this would be an under estimate of some fields, which I went into.

Hay is, in many cases, stacked, sometimes near the barns and at other times in the fields. I saw but few instances in which these stacks were thatched; but in many the stacks were put up with extraordinary skill and care, and so were pretty thoroughly protected against the weather. Mr. Wadsworth has, scattered over his fields and meadows, a great many small barns in which the hay is stored; and at which places his cattle and sheep are fed in the winter, but not housed.

The proper stacking of hay is quite an art, which an Englishman or Scotchman understands well; and if allowed to take his own way will perform with so much skill, I may add, taste, that I have often admired these stacks for their effectual protection of the hay, when well thatched; and for their beauty as picturesque objects in a rural landscape. But it is an art of which in general a Yankee knows nothing, and in which he is commonly a sad bungler; and this not from any want of capacity, but from a deficiency of patience owing to the driving haste with which most things are carried on among us; and from a habit, but too common, of only half doing most things which we undertake.

Of Stock in the Genesee Valley and its vicinity, I can judge but very imperfectly. It is hardly to be considered at present as a stock raising district, the land being chiefly devoted to the growing of wheat and grass. Mr. Wadsworth feeds large numbers of cattle upon his meadows, but many of these are purchased and not bred by him. He has bred, however, some improved stock and has several animals of full and mixed blood. Mr. Le Roy and Mr. Newbold, in York, have a considerable herd of improved animals of a high character. I saw them merely in passing, and regretted that I could not go among them; but they are held in high estimation in the opinion of competent judges.

I scarcely found a farm where any considerable number of cows were kept for dairy purposes beyond the

use of the family. The cows met with general were of no particular breed; and were, as far as I observed, in good condition. Perhaps I should except from this eulogium the cows which go in the highway, a race which, in Ireland, are so much valued for their skill in leaping hedges and ditches; and at sales are always commended for their capacity of "getting their own living." I could get no exact account of any dairy product. The average yield of a good cow in new milk cheese was stated at about 300 lbs., and where her milk was devoted exclusively to butter, at 110 to 150 lbs. per annum. These statements, however, were rather conjectural than ascertained; and to all inquiries respecting the yield of their cows in milk, the stereotyped answer was always made, that they gave a *pailful* at a milking; an answer which I have always admired for its precision, especially as pails are all of one size!

The general impression among the farmers in this part of the country seemed to be, that while the Improved Durham Stock was decidedly to be preferred for its beauty, size, and thrift, yet for milk they were considered inferior to the best selected cows of our native stock. The first crosses have almost always proved well. How far this impression or opinion is to be valued, must depend on many circumstances. It may be mere prejudice or an opinion taken up at hap-hazard; and but very few persons, if any, in this part of the country have had that long and careful experience with the race, that would justify them in coming to so great a conclusion. The truth is, with a few exceptions, we in fact know little of this stock at present; and the haste with which some men approve or condemn, is well illustrated within my own experience, where, for example, an individual farmer of no mean judgment undertook to give their character with perfect decision, whose whole knowledge of them extended to the owning of a half-blood two years old bull for a few months.

If any man, however, chooses to see this stock in perfection, let him go to the farm of E. P. Prentice of Albany; and if he has any prejudices of any kind against the stock, and is not then prepared to yield every one of them, I can only say he is differently constituted from what I am. Mr. Prentice has about forty animals of the Improved Durham Short Horn, of pure blood and of the highest pedigree. He has one cow with seven heifers of her own progeny along side of her, six of which were in milk. A stock of larger size, of more symmetrical form, of equal beauty, of finer feel, of more thrift, of greater productiveness, I never have seen and never expect to see; nor do I expect to see a herd better kept, nor better arrangements for their keeping. To an amateur, to an inquisitive farmer, who desires to see what skill, intelligence and care can effect in moulding and improving the animal frame, it is worth a journey from Rochester to Albany on foot to see this stock. It is worth almost as much to see Mr. Prentice's stable arrangements and the tidy manner in which every thing is kept. Some few farmers among my acquaintance, in going there, would hardly know that they were not in their own best parlors. This, however, seems to convey a slight reflection upon some farmers' wives; but that is not my intention; and as I would not upon any account be disrespectful towards the ladies, I beg my readers to draw black lines around this paragraph and consider it as "expunged."

I have only to desire that Mr. Prentice would by a lactometer ascertain the qualities of his milk; and then that he would ascertain the actual yield in butter of several of his animals for a week or so; and when this is done, that he would show his benevolent countenance in the New Genesee Farmer and let our readers know all about it. Our friend Tucker of the Cultivator, has too much generosity to complain of this; or to think we have jumped over the fence into his pasture

with a view to catch and bridle one of his best colts. He has a full team always in his own stables.

The farm work in this part of the state is performed almost exclusively by horses. The horses in general are horses of all work. No horses among us are raised for the turf, and the various vehicles in use, wagons, deerhorns, buggies, sulkies, &c., have put saddles almost wholly out of use. This is to be regretted, for there is no more manly, healthy, and vigorous exercise, for man or woman, than riding on horseback. The horses in general are of a medium size, and impressed me favorably.

Of the comparative expediency of keeping horses rather than oxen, or otherwise, I shall not speak in this place. Confidently as some persons have decided in this case for themselves, there are yet two sides to the question. A pair of horses is required on almost every farm for market, church, visiting and business from home; but if the team must be extended beyond this, it is well worth considering whether oxen may not be kept to more advantage than horses. We shall now give no opinion in the case, but suggest it for farther inquiry.

OF SHEEP I saw some flocks, but not many large ones. Mr. Wadsworth has several thousand; the Shakers at Groveland have a considerable flock; The-ron Brown of Wheatland, has a flock of 500 sheep of mixed blood. His wool brought this year 28 cts. per lb., last year 35 cts.; the previous year 44 cts. The average yield of this flock, where there was a large proportion of wethers, was 3 lbs. 4 oz. of washed wool to each sheep.

In his opinion, 7 sheep require a ton of hay for wintering. Hay is valued at 5 dollars per ton. The annual increase of the flock is reckoned at 25 per cent. The value of mutton here is very little, and that increase will do little more than keep the flock good. Giving, however, the flock the advantage of all the increase, the account may be thus stated:

Wool, 3 1-4 lbs. at 28c.	91 cents.
Lamb, 1 in 4 or 1-4lb.	25 "
	116
Keeping 1-7 of 500,	71 cents.
Pasturage, say	40 "
	111

Net balance in favor of sheep, 5 cents.

This presents no great encouragement to the sheep husbandry. Mr. Brown is of opinion that swine and cattle are not worth raising beyond the wants of the family. I give it as the opinion expressed by him and some other farmers to me, but as a matter in my own judgment admitting of several qualifications. It is a complex question, in which a good many elements are involved, and my very imperfect knowledge in this case does not authorize me to pronounce with decision.

The value of land is rated here at 50 dollars per acre. The yield of hay estimated at 1 1-3 tons. The hay at the above estimate would be equal to \$7.50, and the expense of getting can hardly be less than \$2.50 per acre, leaving 5 dollars income in favor of the land. But on a farm it must be considered that there is much land in wood or in fallow, or otherwise unproductive; and there are uncertainties attending all crops and seasons.

I regret the necessity of leaving my journal in this case unfinished; but without occupying more of the columns of the Farmer with my own lucubrations than I am willing to do, I must postpone several miscellaneous notes to another number.

To Friends and Correspondents.

We have the pleasure of acknowledging the receipt from William Turner, gardener to Nath. W. Howell

in Canandaigua, a parcel of gooseberries of the finest description in size and quality. They might any where challenge competition; and they show how much may be done by care, pains-taking and skill. "I can't do it, I can't do it, I always have had luck." This is the stereotyped cry of the Do-little family; a very numerous progeny and a very ancient race, who were born in the afternoon and never yet quite got their eyes open nor their shoes up to the heel. We are happy to recognise one of a different race, who has found out that gooseberries will not always mildew.

Messrs. Elwanger and Barry have favored us with a splendid specimen of the Bolmar Washington Plum, quite as large as hen's eggs, and with some bouquets of exquisite beauty. We have transferred the plums to fair mouths, whose tints are ruddier and perfume sweeter even than that of the richest nectarine; and the bouquets to fair hands, or rather may we not say to flowers even more fair, one of which is as much, even in this land of monopolies, as any one of us poor sinners dares appropriate to himself, though of this bright order we are compelled to say

"Full many a flower is born to blush unseen
And waste its sweetness on the desert air."

We should like to say more, but there is somebody looking over our shoulder.

GARGET.—A correspondent inquires, what is Garget? It is a root or plant well known among us, and commonly called Poke, having a reddish stem, broad pointed leaves, and bearing large clusters of black berries. Its botanical name is *Phytolacca decandra*.

J. E. T.—A friend remarks in a letter to us: "I have read the articles of J. E. T. twice over. Such a correspondent is invaluable." We entirely agree with him and regret that the pressure of business engagements deprives us this month of his usual welcome contributions.

BERKSHIRE FARMER.—We have received the first number of the *Berkshire Farmer*, which, having been abstracted from us, we request our friend the Editor to send us another. We had only time to see that it is a monthly agricultural paper of 8 folio pages, published at Pittsfield, Berkshire Co., Mass.; and well printed, at 50 cents per year. It is to be edited by Wm. Bacon of Richmond, whose communications in the *New Geneva Farmer*, the *New England Farmer*, and the *Northern Light*, over his initials and dated at Mount Osceola, have been always welcome to our readers. We promise those who choose to take the *Berkshire Farmer* under his care, that it will be instructive, useful, safe, piquant and agreeable. Its editor is worthy of respect for his talents and acquirements; and regard and esteem for his refined taste and his excellent moral qualities. We part with him as a correspondent with unfeigned regret, and welcome him with an equal pleasure to the editorial fraternity.

THE FARM HOUSE OF THE XIXth CENTURY.—This publication has just appeared from the press of S. S. Haskell, No. 138 Fulton street, New York. It is a translation of the celebrated French work, an *Encyclopedia of Agriculture, Maison Rustique*, in four closely printed 8 vo. volumes, by Elizur Wright, Jr.; and is to be published in semi-monthly numbers of 48 pages each, in forty numbers, and at 25 cent each.

The Translator is perfectly competent to the task and promises to add some notes, which may better adapt the work to the wants of American Farmers. We have known and owned the work in French for some time. It is a complete work and highly valuable to the Farmers. What the French do in this way they do most thoroughly. We hope all the intelligent farmers in the country will seek to possess it; and we shall from time to time, as the numbers are sent to us, give some account of their contents. It will be embellished with 2000 engravings, and we trust it is not too late to express the hope that the public patronage will

be such as to allow it to be printed on better paper and with a fairer type than that in which the first number appears.

Several valuable communications already in type are necessarily laid over. The valuable communications from J. D. in Monroe, Michigan, are just received, but too late for any farther notice in this number.

The following description of the visit of our friend to the Elysian Fields, really makes our mouth water. We have no doubt it is every word true, graphic and imaginative as it may seem to any; and we only regret that we could not ourselves have accepted the polite invitation of the principal of this Academy to attend on this interesting occasion. But how we ever got our friend back from this Paradise we know not, unless he was driven out for looking, it may be, too wishfully at some of the forbidden fruit; and how he should ever dream, old and rusty as we are, that we could have an ear for this celestial music, is beyond our imagination. "O! the days of anld lang syne." But we mean to go so far this autumn as at least to peep into this Eden; and if our friend Flora, we believe the privileged resident of this charming vicinity, will condescend to give us her particular *locale* we mean to let her know in person how sincerely we respect her talents and sentiments and desire a nearer acquaintance. Here we are treading again upon dangerous ground, a sort of volcanic region, full of combustible matter, and therefore stop.—Ed.

Aurora.—Cayuga Academy:

MR. EDITOR—I spent two days the past week at Aurora, during the public examination of pupils of this Academy. Let me advise you to visit this charming place; sail on the beautiful lake and feast your eyes on the unrivalled scenery; then luxuriate among the highly cultivated fields, verdant lawns and shady groves; taste the delicious fruit, hanging in profuse abundance in the orchards and gardens; observe the beautiful flowers and clustering vines surrounding the tasteful dwellings; partake of the generous hospitality of the intelligent and wealthy inhabitants, and (*tout beau!*) listen to the sweet music or sprightly conversation of the beautiful and accomplished ladies—and you will agree with me, that Aurora is indeed a charming place. But this is a digression.—

The Academy is the oldest institution of the kind in this part of the country, having been in successful operation for nearly half a century. Some of the ablest men in the state, were, in early life, participants of its advantages. It has permanent funds, which essentially increase the facilities of education. A full board of qualified and faithful teachers are employed, and the apparatus and library are excellent. The course of education deserves especial commendation, for giving a thorough knowledge of the English language. This department is under the personal charge of that well known philologist, SALEM TOWS, author of 'Town's Analysis,' and other valuable works. Mr. Cooper, the Principal, appears well qualified for his situation; and much credit is due to Dr. Thompson, teacher of Botany and Chemistry, also to the Rev. C. N. Matton, lecturer on Mental and Moral Philosophy. The catalogue of pupils for the past year numbers 138 males and 70 females—total, 208. The examination occupied three days, and was highly creditable to both teachers and pupils. An excellent address was delivered at the close by GEN. J. A. DIX of Albany. M. B. B.

Rochester, Aug. 18th, 1842.

To Preserve Flowers.—Be careful not to press the flowers too hard at first, and change the blotting paper frequently to absorb the moisture, increasing the pressure as the flower dries.—Eng. Pub.

Importance of the Education and Training of the Young.

In that model of a good newspaper, or what in our humble opinion a newspaper should be, the Boston Daily Advertiser or Weekly Chronicle and Patriot, we find some extracts from Horace Mann's Oration, delivered in Boston on the last 4th July. Mr. Mann is the devoted, enlightened, and most efficient Secretary of the Board of Education in Massachusetts. To him the State owes a debt, which no money can ever repay; he has broken up ground, which had lain long inert and barren, and cultivated and enriched and made it productive; and sowed seeds in drills and broadcast over the land, which will continue to bear precious fruit for centuries and ages to come. High as we estimate our own art, and in some respects in importance it yields to few others, yet what is any system of agriculture compared with that moral husbandry by which the seeds of virtue are to be quickened into life and souls are to be trained for immortality?

We labor in our humble sphere that the earth may be made productive for the comfortable subsistence, and be embellished and beautified for the enjoyment and delight of man; but what are its richest fruits or its brightest ornaments compared with the adornments of the intellectual nature, and the moral fruits of the heart and mind? We aim to give the finishing bread, and to cause the earth to yield to industry and skill those supplies which God designed that industry and skill should command; and without our art and our efforts, all other arts and all other efforts won't the vain. We hold, likewise, that the success and improvement of the great art which we profess, are eminently the work of true philanthropy; and have, in various ways and forms, a serious connexion with man's moral welfare. But we are not vain nor simple enough to place any merely worldly acquisition, any physical improvement or advantage, in comparison with the blessings of high intellect in its connexion with high moral culture; the bread which feeds and sustains our animal nature, in comparison with the true bread of life, wisdom, virtue and piety; the elements of the immortal soul.

Mr. Mann's views on the subject of the infinite importance of this intellectual and moral training, are most admirable. We expected from him in this case as much as we could have expected from any man, and he has acquitted himself, so far as these extracts go, as well as any man living could have done. In beauty, in power, in true eloquence, above all in their fearful seriousness and solemnity, we do not know when they have been surpassed.—*Ed.*

"O! better, far better, that the atheist and the blasphemer, and he who, since the last setting sun, has dyed his hands in paricide, or his soul in sacrilege, should challenge equal political power with the wisest and the best, that these blind Samsons, in their wantonness of their gigantic strength, should tear down the pillars of the Republic, than that the great lesson which Heaven, for six thousand years, has been teaching to the world, should be lost upon it;—the lesson that the intellectual and moral nature of man is the one thing precious in the sight of God; and therefore, that until this nature is cultivated, and enlightened, and purified, neither opulence nor power, nor learning nor genius, nor domestic sanctity, nor the holiness of God's altars, can ever be safe. Until the immortal and god-like capacities of every being that comes into the world are deemed more worthy, are watched more tenderly, than any other thing, no dynasty of men, or form of government, can stand, or shall stand, upon the face of the earth; and the force or the fraud which would seek to uphold them, shall be but "as fetters of flax to bind the flame."

"Let those, then, whose wealth is lost or jeoparded, by fraud or misgovernment; let those who quiver with apprehension for the fate of all they hold dear; let those who behold and lament the desecration of all that is holy; let rulers whose counsels are perplexed, whose plans are baffled, whose laws defied or evaded;

let them all know, that whatever they do for God, for the great and glorious God of the night, and heaven and angelic childhood.

"Remember, then, the child whose voice first rises, to-day, before that voice shall whisper sedition in secret, or thunder treason at the head of an armed band. Remember the child whose hand, to-day, first lifts its tiny thumb, before that hand shall scatter fire-brands, arrows and death. Remember those sportive groups of youth, in whose halcyon bosoms there sleeps an ocean, as yet scarcely ruffled by the passions, which soon shall heave it up with the tempest's strength. Remember, that whatever station in life you may fill, these mortals,—these immortals, are your care. Devote, expend, consecrate yourselves to the holy work of their improvement. Pour out light and truth, as God pours sunshine and rain. No longer seek knowledge as the luxury of a few, but dispense it amongst all as the bread of life. Learn only how the ignorant may learn: how the innocent may be preserved; the vicious reclaimed. Call down the astronomer from the skies; call up the geologist from his subterranean caverns; summon, if need be, the mightiest intellects from the Council Chamber of the nation; enter cloistered halls, where the ascetic monk over superfluous annotations; dissolve conclave and synod, where subtle polemics are vainly discussing their barren dogmas;—collect whatever of talent, or erudition, or eloquence, or authority, the broad land can supply, and go forth, and TEACH THIS PEOPLE. For, in the name of the living God, it must be proclaimed, that licentiousness shall be the liberty; and violence and chicanery shall be the law; and superstition and craft shall be the religion; and the self-destructive indulgence of all sensual and unwholesome passions, shall be the only happiness of that people who neglect the education of their children."

Miscellaneous Matters.—Chance of Plants.—The Cut Worm.—The Pea Bug.—The Curculio.—The Spider.—Flies Eating Woolen Yarn.—Summer Potatoes.—Murrain in Cattle.—Wheat and Chess.—Horn Ail.

We publish the subjoined letter with much pleasure. We cannot endorse all the opinions and assertions of our correspondent, and are not willing to oppose them. It is delightful to see these workings of an inquisitive and observing mind; and the letter is of great value, if it did no more than present so striking an example of intelligent and exact observation. The difference between living in the country or travelling through the world with our eyes open or our eyes shut, is beautifully illustrated by such an example.—*Ed.*

Mr. ENRON.—Perhaps you may think it strange to hear from a friend in Ohio. I have taken your paper ever since you commenced the New Genesee Farmer, but I do not recollect of seeing anything shewing the manner in which seeds of vegetables mix or amalgamate with others of their own species. On almost all kinds of plants and trees there are false and bearing blossoms, which might be termed male and female, on the same tree or plant. The dust or flour which these blossoms contain, is necessary to form the seed; now if this flour is taken from the male blossom of its own plant or tree, it will produce genuine seed, but if it is taken from another individual of its own species, it will produce mixed seed; hence the reason why apple seeds do not produce trees bearing fruit of their own quality; but the quality of the fruit is not changed, it being the covering of the seed. I have broken open a squash and taken out seeds to plant, when, to my utter astonishment, they produced half pumpkin and half squash, good for nothing for either, except one vine, which produced its original variety. The question may properly be asked, what agent conveys seed from one plant to another? I answer it is the bees, and all other insects that delight to visit the flowers of summer, carrying with them the dust which forms the seed. All kinds of potatoes may be planted together in one field without mixing, so with all kinds of beets and turnips. A white man and negro may as easily mix by working in one field together, as those plants can by growing together; the

only time of amalgamation being when in the blossom. I must dismiss this subject for able hands to finish.

Will you accept some hints on the natural history of some of our formidable insects.

The Cut Worm or Black Grub.

This worm is produced from an egg, generally in the month of May, and grows rapidly, shedding its skin several times, until it comes into the chrysalis state. It remains in this torpid state from 8 to 12 days, depending on the temperature of the weather, from whence it comes forth the perfect miller or moth, resembling the bee moth, though a little larger and of a darker color. Its time of perfection is generally from the first of July to the middle; its food consists of all kinds of vegetables and green roots; it commits its depredations in the night while in the worm state; it goes through with the same operations that the silk worm does, except spinning. The millers deposit their eggs in the ground in autumn, where they remain during winter.

The Pea Bug.

So well acquainted are most persons with this insect, that it needs no description, but the way it gets into the pea is not generally known. The egg is deposited on the outside of the pod; it is of a yellowish color, resembling that of the horse bee, though not quite so large; it adheres to the pod opposite to the pea on each side, when it hatches and bores its way through the pod into the pea, where it is transformed into a bug, and remains there until the next spring, when it comes out and flies about and waits for the pea to grow.

The Curculio.

The insect or bug that destroys plums and cherries, resembles the pea bug in size and color, except the head, which is very long and slender and armed with sharp teeth or a point, with which it perforates the skin in a circular form and deposits the egg, which hatches and bores its way to the stone, which immediately causes it to perish and fall off; this insect can fly. I suppose it is what is called the curculio, though I have not seen it fully described. When this insect is held between your thumb and finger it will make a squeaking noise.

The Spider.

This insect is a friend to agriculture, although it is considered to be disgusting and poisonous, and many therefore that will start back and scream at the sight of a spider, as if it were a venomous reptile. This is because tradition and superstition have got possession of our senses. I have been bit by spiders and received no more injury than from a flea; yet there may be some spiders whose bite is poisonous. The spider has eight legs and eight eyes; it sheds its skin several times in the course of its life; it sometimes survives the winter in a torpid state; it is, like other beasts of prey, capable of enduring hunger a long time; its food consists wholly of flies and insects, which otherwise would devour our crops. Look at the multitude of webs in the morning after the fog has left the air, and you will see your field nearly covered, and all of these little nets are set to catch insects. How many thousands are daily destroyed. Yet prejudice has got such hold of our minds that we frequently step aside to crush them and destroy their nests. Whoever is guilty of doing so, is not acquainted with the history of the spider, or they act against their own best interest.

Flies Eating Woolen Yarn.

We often hear our women say the flies have eaten our yarn; but this is not correct. I will clear the flies of this mischief for the good reason that they have no teeth. The insect that does this mischief is a little miller or moth, which deposits its eggs in the

of cloth, which there is no difficulty in procuring, and which is made of yarn or wool and forms itself a cell of the same material, and then changes into the crystalline state, from which it comes out a perfect murrain.

How to dig Potatoes for Summer Use.

Look round your potato hills and where you see ground is cracked there you will find a potato; dig it out carefully with your fingers without disturbing the roots, and place back the dirt carefully, so on until you have enough for a meal. If this is properly done, there will be no leep potatoes to dig before fall. It operates just like picking cucumbers; you will set more if they have not got their growth, the tops will not die until they have brought in to maturity.

Murrain in Cattle.

This dreadful disease in cattle is sometimes caused by leeches or bloodsuckers. The cattle swallow them when small in drinking from brooks and marshes. As they eat their way through the stomach into the liver, it causes it to ulcerate. They sometimes eat their way into some large blood vessels in the liver, which causes the animal to bleed to death immediately.

Some may feel disposed to dispute the above statement, but I can bring living witnesses that have in them out of the livers of cattle and put them in a jar of water, and they would crawl just as they do in brooks. Cattle kept in swampy pastures are apt to die with the murrain than those kept in pastures. I understand that cattle from Ohio do well so well in the eastern markets as those from other states, on account of their health. Perhaps there are other causes of the murrain not known to me.

I think I have let down one bar at the end of a long which leads to the field of discussion, and I leave you or some of your able correspondents will enter in and give the matter a fair examination.

Wheat turns to Chess.

It has been stated by some that oats that live through the winter turn to chess, and chess, if sown, produce chess; so here we have three ways to produce chess and but a part of one way to produce wheat. It is no more absurd than to think that the weather affects the growth of vegetables.

Horn Ail in Cattle; Inquiry.

Does cutting off the end of the tail prevent this complaint, or is nature imperfect? Tell who can.

Yours, respectfully,

GAUIS KING.

Camden, Gauga Co., O., 1842.

Conditions at Ploughing Matches.

We have delayed the publication of the subjoined until now, believing it would be more seasonable and attract more attention as the Fair and Ploughing Matches approached, than if given earlier. Its suggestions are all well founded. It is fully to insist on such exhibitions and competitions without prescribing exact rules, and without making those rules absolute and inflexible.

As to premium in ploughing matches should ever be upon hurrying the work faster than at a rate at which the team could work comfortably through the furrow.

A ploughing match is not a race, nor a match at time. The depth of ploughing, the width of furrow slice, and the angle which it is laid, or whether to be laid flat or completely shut in or lapped, shall all be matters particularly prescribed. So also the time of entering, the time for calling the team and the time of starting, should be named and fully and absolutely observed. There is no end to evils which come in all such cases, from a relaxation of the rules, or from any extraordinary indulgence.

As said you cannot make farmers come up and adhere to such rules. Then we would give up the com-

petition. But this would be no difficulty in any case, provided it is understood that all the conditions are absolute, and that the committee will do their duty without fear or favor. In accommodation coaches, how few persons will be found ready at any precise moment for starting; in rail-road and steam-boat conveyances, where the precise minute for starting is fixed and where no grace is ever allowed, not one person in thousands is ever out of season. There is no difficulty in such cases in compelling people to be exact and punctual, and the advantages of such exactness in every department of life are infinite.—Ed.

MR. EDITOR—I feel desirous, at the approach of spring, to offer a few remarks on a subject, which I was glad to observe brought under your notice by your scientific and practical correspondent, Mr. Adams of Bloomfield, in your January number. I allude to the subject of ploughing,—a work of all others of paramount importance to the farmer. Considering the acknowledged importance of this primary department of agriculture, it seems surprising that so little progress has been made in it. I can only account for this on the principle that Agricultural Societies in America, without prescribing fixed dimensions, or attaching sufficient importance to the excellence of the ploughing, have awarded the premium for good ploughing to the competitor who skims over the ground in the shortest space of time, of which we had lately a notable instance in the neighboring county of Wayne.

While this country, in the arts and sciences generally, is keeping pace with the nations of the world, and in many instances going ahead of other countries, it is to be regretted that our farmers, laying aside the prejudices of the past, will not venture upon a style of ploughing more conducive to their real interests than the hurried, superficial mode now so much in vogue. We still hope, however, to see in future Ploughing Matches Mr. Adams' suggestion adopted,—that the dimensions of 8 inches in width, and 5 in depth, be prescribed, and that the time of performance shall be specified—say an hour and a half to the quarter of an acre. The judges ought then to award prizes to those who shall most strictly attend to the directions given, paying due regard at the same time to the furrows being straight, and laid at the proper angle, somewhere about 45 degrees.

The excellence of the ploughing, and not the speed at which it is performed, being thus made the subject of emulation, we might then hope for a general improvement in the art of ploughing.

Care should also be taken, as Mr. Adams suggests, that a piece of ground suitable for the trial of skill be selected; but until a proper method of ploughing be encouraged by agricultural associations, (as suggested in the hints I have given above,) no farmer would be willing to have his ground mangled and scratched in the manner we have witnessed at some recent exhibitions.

Yours, respectfully,

A CANANDAIGUA FARMER.

Canandaigua, February, 1842.

Western Prospects.—Illinois.

MR. COLMAN—Though wholly unused to writing public communications, yet I send you this hoping that a true, unpolished account of the prospects and doings of those living in what was once termed the "Far West," may be of interest to some of your numerous readers.

We are now in the midst of an abundant harvest. The wheat crop is very heavy, of the finest berry I ever saw. Oats, barley, and indeed all small grains, promise a rich reward to the Western Pioneer.

The corn crop is somewhat retarded in consequence of cold, wet weather in the months of May and June,

but should the fall season be favorable, there will be an average crop.

There are great inducements here for the emigrant. Improved farming can be had at about their first cost. Many noble situations are yet "unclaimed," with plenty of timber and excellent prairie adjoining,—the expense of the first ploughing or "breaking" is from two to three dollars per acre.

But although the soil is exceedingly well adapted to all kinds of grain, I think the Western farmer will eventually find it to his advantage to pay his greatest attention to raising stock, particularly sheep. When we take into consideration the low price of land, the short, mild winters, and the small expense of transporting wool, I think that the western farmer can raise it for one third or one half less than the New Englander. Common sheep are readily purchased at from two to three dollars; they grow large and thrive well on our prairies.

We are much in want of good breeds of stock of all kinds. Farmers are waking up in regard to the necessity of improved stock. They are purchasing some good Durham cattle, and we have a few fine Berkshire hogs.

We have some good nurseries, and some fine young orchards just commencing to bear fruit. Here I would inquire whether the wheat crop is injurious to young apple trees? I planted an orchard two years ago, and sowed the ground with wheat the same fall. Many of my trees died, the remainder look unhealthy, while my neighbor's orchard looks fine and healthy; his trees having been obtained from the same nursery and planted the same time, and on the same kind of soil. I have a few peach trees from the seed, planted two years last April, that now have peaches on them.

Building materials are cheap on the Mississippi River. Good pine lumber can be had at almost any landing at from ten to twelve dollars per thousand feet. Shingles from two and a half to three dollars per thousand.

Should you think this or any part of it worthy a place in your valuable paper, you may hear from me again.

J. A. S.

Albany, Whiteside Co., Ill., July 19.

From the Maine Farmer.

Prevention of Smut.

I have for the sixteen years last past, with complete success practised the following method, viz: Washed the seed wheat and drained off the imbibed water through a common basket. In this moist condition put it into a tight tub, long box, or trough; and for every bushel so prepared, dissolve two ounces of the blue vitriol in warm water, turned it into the wheat, and with a shovel stirred it so that the liquid should penetrate the whole mass. This may be ascertained by the color. The wheat will assume a greenish cast, where the liquor has come in contact with it.

This method of preparing our seed has become almost universal in this neighborhood, and we hear nothing of smut except from a distance.

OLIVER CROSBY.

Postage and Fines.

Some remarks have been made in a former number of the Farmer in relation to writing on the margin of newspapers, and in defence of the course of the postmaster general in fining individuals for merely writing their names or compliments. The object of the post-office department is the accommodation and not the annoyance of THE PEOPLE; and when its officers go further than this in restrictive power, they become tyrants. Writing on newspapers to evade the payment of letter postage, is defrauding the government, and should not be allowed; but no man would ever write a letter merely to say "A. B.'s compliments to C. D.," consequently fining a man for writing it on a paper, must be regarded as a wanton exercise of arbitrary power. How much more so then, to make him pay five dollars for merely putting his initials on the paper, which cannot in any possible way defraud the department.

JUSTICE.

Intellectual Culture.

Feeling somewhat gratified with the flattering notice bestowed on my former communications, and not willing to appear indifferent to, or negligent in returning a compliment, or in endeavoring to repay a "good turn," I have resumed my pen; not, however, without the conviction that many, very many, mothers and daughters of the surrounding country, enjoying superior advantages, both of acquired and natural abilities, are far more capable of enlisting the attention of the heedless and casual reader, and of inspiring the minds of the too busy-workers with a love for intellectual culture and general improvement. Yet I do not feel unwilling to render my "mite" in a cause replete with interest, to the farmer as well as the statesman, to the farmer's children as well as the collegiate student.

The first most natural duty of man, appears to be, to provide for the body sustenance and raiment. Our appetite prompts us to satisfy its cravings for food, our pride and ambition and the sense of heat and cold induce us to provide clothing; but often, through too much care and anxiety for these, the appetite of the mind becomes weak and unhealthy; its perceptions and energies are blunted; its longings for knowledge and inquiry into the wonderful operations of animated existence and inanimate matter are suspended, and finally almost extinguished, until some whispings of conscience penetrate the ear of the soul, or some thunderbolt of omnipotent power startles anew into existence the hushed and neglected spirit, the crushed and abused intellect, the intelligent soul, which has been entrusted to our keeping.

The enquiring mind cannot be satisfied and can never be stilled. It is boundless in its desires, and encroaching in its efforts. It is capable of infinite expansion and endless duration; but dependent upon the will and judgment of its possessor for a proper cultivation to bring it forth in its native strength and majesty, in its purity and dignity, in its beauty and loveliness.

My feelings upon this subject induce me to address myself mostly to the fathers and mothers employed in the busy occupations of agriculture. Although I have not the experience of mature age, yet I hope the years employed have not been altogether unimproved; and while I would speak with the utmost deference to those older and more experienced than myself, I would solicit their attention to a subject involving the deepest interests of every individual. All acquainted with the history of the farming population of our country, are aware that they have had, what is generally termed, rather hard times to get through the world with credit and honor, and secure to their posterity a competence, an independent station in society. They have, as a general thing, commenced life, not in affluence and ease, but with a few hundreds of dollars, and many with nothing but health and a vigorous determination to lay

themselves a foundation of wealth and its advantages. With little or no education, and few opportunities for improving it, with few clothes and no money, how many of our forefathers have commenced the cultivation of the wild and cheerless forest; hardly giving themselves nature's just repose, so intent were they on acquiring by the labor of their own hands, a support—yea, more—a comfortable, cheerful home for their children.

But while they labored to secure for their families the necessities of life, they seem almost to have forgotten that the mind, the foundation of all rational and exalted enjoyment, had been committed to their united care for direction and improvement. Amidst the bustle of business, the fatigue of labor, and the anxieties, cares, and perplexities of life, the cultivation of the mind has been too much neglected; and the false and injudicious opinion that the farmers had no use for much education, that there is nothing in his pursuits to draw forth the intellectual spirit within him, and that

it is of no farther importance to him than it affords facilities for the accomplishment of business, to advance his wealth and influence, has by degrees, detached, in a great measure, from his noble and generous heart, the purest sources of human enjoyment. That part of the subject has been too willingly relinquished to the nothing-to-do and professional classes. But it ought not, it must not be thus.

Upon the father, as the head of the family circle, devolves the duty of establishing a course of regular instruction at the fireside; and the mother should be diligent and unwearied in her efforts to have those regulations observed and adhered to. But, says the busy farmer, what time have I for instructing my children. Let them go to school in the winter, and if they do not learn it is their own fault. But fathers! reflect one moment. Your children's characters are molded by your own hand; and their present and eternal happiness may almost with truth, be said to rest upon your conduct. Let the father set the example—let him, in conversation, by reading and study, impress upon the youthful minds of his children the necessity, the advantages, the happiness, and the duty of intellectual culture; let him but succeed in the single effort of inculcating a love for reading, and then select such books as will both enliven the imagination and enlighten the understanding; that will raise the ambition and create a thirst for improvement; that will awaken the curiosity and induce meditation; that will fire the soul with courage, animation and perseverance; that will establish a love for virtue, religion and justice; and you will have little trouble to keep that child in the path of rectitude, in the road to knowledge, in the straight and narrow way that leads to happiness here and infinite enjoyment hereafter.

But says one, I have no leisure for reading anything more than my political and agricultural paper—I can scarcely spend time for that—and as for buying books for my children, I have no money to spare,—there are other things that must be attended to for all that. But what is it that must be attended to? a few more acres of land purchased? a fine span of horses and a few more cows? Or perhaps these things are already purchased and the money must be made out. Well, I am glad for one that you can have these things; I am heartily rejoiced to see the hard working man enjoy the fruits of his industry and economy. But—that little conjunction, but, has got a word to say—does the father, the lawful possessor of a rich and productive farm, the honest and rightful owner of fine horses and sleek cattle, of numerous herds and flocks of every kind, will he say, I cannot afford time to read anything but a paper or two? that I cannot afford a few shillings or dollars to purchase books for my family? Does he fancy that the all-wise, bountiful, benevolent father, the author, creator and preserver of himself, his family, and his possessions, will, at that great and awful tribunal, say unto him, "thou good and faithful servant, enter thou into the joy of thy Lord?" Think you that he will believe that you had no time to devote to the improvement of the mind; that you had no time or talents for the instruction of your children; no money to purchase for them the written volumes of information and knowledge? Ah! there is little doubt, there is but one conviction as to that final opinion, that eternal decision.

FLORA.

Brutus, Cayuga Co., August 7, 1842.

For the New Genessee Farmer,

On Threshing Machines.

MR. COLMAN—I noticed in your July number of the Farmer, what you say as well as what number of your correspondent say in regard to threshing machines. If you have no objections, I would like to have my say on the same subject.

In the first place, with all due deference, I dissent entirely with you and your correspondent Y, in regard

to this "partnership" or "company concern;" for the simple reason, that it is not often that two or three farmers can be found that are equally careful and particular in the use of machinery; and without careful attention, the best and strongest will sometimes break or get out of order. I will state a case in point, and I have no doubt there are many others of the same stamp.

About six or seven years ago, four of my neighbors purchased in company one of Fox and Borland's machines. The first year, each one threshed out the crops, and all went very smoothly. Two out of the four were careful men, and when in their possession all was right. But mark the difference; the four partners, after using the machine, neglected to remove it under cover, and left it at the back side of his barn exposed to the weather, until it was wanted again the next season. When another of the owners was desirous of threshing out some rye, he sent for the machine, which was three miles off, and after considerable time had been consumed in cleaning, oiling, &c. every thing prepared, the horses hitched on, the machine started, when lo, and behold! one of the iron wheels was found to be broken, and instead of three men, the hands were discharged, and he was obliged to send to a machinist to have it replaced, which to several days; and the consequence was, the flail had to be used to thresh for immediate use, and a proposition was made to sell out and close the concern. "What is every one's business is no one's business of course the machine must suffer."

Now, sir, I raise but little grain of any kind, and find it a slow operation to beat it out with the flail besides there is considerable waste, in its not being threshed clean; to be sure, the cattle will not do it any the less on that account, but to say the least is a slow and tedious operation.

This reminds me of the Dutchman who was asked why it was that his horses were always so fat, which he honestly replied, "I don't know, for I give them nothing but straw, and that is not half threshed. It is presumed he used the flail, or what is more common with them, beat out the grain with his horse feet."

The machine made at Hillsdale is, I believe, Allen patent, and a very efficient one it is too; and the price for which it is sold, is a consideration not overlooked in the present depressed state of the times.

My objection to Hibbard's machine is, that it takes up too much room—cannot be worked in storm weather—too much time consumed in preparation—requires a driver, and from the description, too complicated. I concur in opinion with your correspondent Y, that a two-horse power is preferable, as it costs more, and can be worked by one horse if required. An endless-chain power can be placed on a barn floor—takes up little room—can be removed from one barn to another and put in operation in a few moments.

One object in addressing you this communication is to answer the inquiries contained in several lately received on the subject, and whether "Hap power and threshor hold the same place in my eye as it did when I recommended it to the notice of farmers, in the third volume of the Cultivator 1837."

As I observed before, I cultivate but little grain, from 900 to 700 bushels of all kinds; still I consider a threshing machine necessary, and procured 1836 one of "Hale's Endless-chain Power Threshers," which I have used ever since, for thrashing, sawing and grinding; and what is very extraordinary, no accident has occurred, nor have I expended one shilling for repairs; and it is now in as good order, with the exception of the floor on which horse walks, which is much worn and may require

sing in the course of one or two years. I can, therefore, say that "it still holds the same place in my opinion that it did in 1837," and that I have never regretted the outlay, and consider it one of the best measures that has ever fallen under my observation.

From the description of "Hubbard's Power," I did think it complicated; not so with Hale's, which I will attempt to describe. It is a self-supporting chain, with a wood floor, running on an inclined plane, and occupies a space of three by ten feet. Although the box in which the horse walks is narrow, of four horses only one proved so refractory but that they were made to work; and to work it to advantage, it requires a heavy, free, quick-stepping steed, with which from 60 to 70 bushels of wheat or rye, and from 80 to 100 bushels of oats can be threshed in one day. The threshing is an open or piston cylinder and concave, set with small teeth at 13 inches long, secured by screws, and with the option of breaking three or four of the teeth with or without, no accident or expense has occurred.

In 1841 I procured one of Pitt's *Separators and Binding Machines*, and attached it to my threshing machine, which does not seem to increase the labor of the horse a trifle, and delivers the grain clean for the bag; I consider a great saving of time and labor; and the separation is more complete. When the threshing is performed at one operation and the fanning at another, it requires more room on the floor, it generally takes as much time to clean up as it takes to thresh. With two men and one horse, I can thresh, bind up the straw, stow it away, and put bushels of oats into my granary, in as good order when passed through the fanning-mill separately, as I must say I prefer to have the two operations performed at the same time.

Mr. Pitts is now in your section with some of his machines, so improved that they will thresh and clean such grain, I will venture to say, as any other horse; and I have no doubt a discerning public will appreciate their value, and encourage an industrious and ingenious mechanic.

It has been said, with how much truth I will not now try to say, "that Pitts' machine is in advance of age—that the farmers are not prepared for so powerful a machine." The price at which he holds them is to be the greatest objection; still, when we take into consideration the advantages they have over the old, viz: can be used in an open field; will thresh clean at the same time, as much grain, and do it well, if not better than any other machine, with less power and less hands, it cannot after all be deemed a dear machine at \$250. His horse power is very strong and works remarkably easy, and is so adapted as not to be easily put out of order.

At the time I purchased my machine, Mr. Hale ascertained them at Waterville, but soon after returned and established himself at Rome, where, I have been informed, he made some improvement in the threshing machine. This establishment was burned down a few years since, and he then removed further west, so that place I am not advised. It would be well to know who would make known his whereabouts, by an advertisement in the Farmer.

From the six years' experience I have had with his machine, I would recommend them to the farmer who threshes from 600 to 1000 bushels of grain, and to the farmer who cultivates his thousands of bushels of old, without any disparagement to them, advise the purchase of Pitts' Threshing and Separator, as for economy as dispatch.

Wheat was selling at Chicago at 62½ cts., Aug. 23. Buffalo, 62 cts., Aug. 29.

Reply to John Farmer on a National Tariff for protection.

MR. COLEMAN—Your correspondent, John Farmer, travels without his host when he undertakes to suspect me of mistaking facts. Had he been as well informed on the subject of our National Tariff, as he is refined and witty, he would have known that the high tariffs of 1828 and 1833 did not receive even a majority of the votes of the New England States.

The votes from the Journal of the U. S. House of Representatives on the tariff, from 1816 to 1833, will determine this. I would also advise John to read Mr. Salmonstall's report from the committee on manufactures, March 1st, 1842. He will then learn, that the duty on American cotton as proposed by that committee, is made as Mr. Salmonstall asserts, "to conform to a statement made by Edw. Gray, Esq., on manufacture of Eliott's Mills in Maryland." The Yankee Cotton Memorialists tell the committee plainly, that the domestic articles of most of the white, and many kinds of colored cotton goods, need no protection, that they supply not only all the home market, but that they are exported to the average amount of \$3,000,000 annually.

John Farmer asks why the New England Factories closed and their hands unemployed at this time. I will let a manufacturer of my native town answer the question; he says, "We have four cotton factories and one of negro cloth now closed." I asked him if a protective tariff would help them, he replied "that their own cheapness was a sufficient protection; that we had all the home market, fine prints excepted, with a fair demand for export; that over-production, from home competition and the vast improvement in machinery, had long been the cause of very restricted profits to the manufacturer, and that the present stagnation of trade precluded sales even at the lowest profits; hence the necessity of producing less."

But John Farmer does not seem to know that the manufacturing interest of the United States has been fostered more than any other interest, and that its increase has been in full ratio and proportion to the increase of our agriculture and commerce. In proof of it, our imports for the 3 years preceding the first embargo, averaged 22 millions of dollars per annum more than in the year 1840. Since 1808, it is computed that the machinery erected in New England alone, is equal to the labor of two millions of individuals. It also strikes me that friend John has an exceedingly miscolored view of the ramifications of our foreign trade, when he says that "specie is the only article with which we at the north can pay a foreign debt." We paid eight millions in the article of flour alone last year, to say nothing of our other northern exports. But is not the north as directly interested in the exports of the south as the south itself? If John will attend an abolition lecture he can there learn the fact. The north manufactures and carries for the south, and receives its pay in bills on England drawn against cotton, rice and tobacco; and at this time bills are so plenty in the New York market, that specie will pay a freight from England to the United States; so far from our specie running out of the country at this time, the tide has now turned and specie is running in, to fill up the vacuum made by the explosion of our paper bubble. Hence it appears that it was a high tariff and an inflated paper currency, which drove our specie out, and that a reduced tariff and sound currency are bringing it back again. So far from specie going out of the country, it never goes out when it is indispensable for a currency at home; but when bank paper can be made not only to represent specie, but intrinsically to supply its place specie has no longer any office to perform here, and it

will of course be exported where it is of more legitimate use.

I will not accuse John Farmer, as he did me, with wishing to mistake facts, when he says that "our specie has gone out of the country in an uninterrupted stream." I only want to show him that he is mistaken at that point with the report of the Secretary of the Treasury. Mr. Forward sets down the imports of specie into the United States from 1821 to 1841, at \$181,501,510, while our exports for the same time were only \$133,759,910. As much specie is brought over by private immigrants which is not taken into the above account, the amount of our imports of specie is probably much larger than this exhibit. During the present year, 1842, the import of coin has been unusually large. So that there is but little doubt but that for the last twenty years, in spite of all our paper substitutes, the specie of these United States has increased at least fifty millions of dollars.

The difference of opinion between John and myself, is simply this. I want all our great national interests, agriculture, manufactures and commerce, protected by sound and equal laws; but he seems to embrace the delusive notion, that if we stimulate manufactures by taxing the other interests, the home market of the farmer will be so much increased by it, that he can easily dispense with that foreign trade based on exports, which has for the last twenty years furnished us so many luxuries, and increased our specie to the amount of fifty millions of dollars. S. W.

Waterville, Aug. 6th, 1842.

Naagara Agricultural Society.—A Rule of Premiums.

This Society, whose fair is fixed for the 18th and 19th of October, have offered \$500 in premiums. This does them much honor. They add farther, what ought to be considered every where as absolute, that the conditions of competition and premiums will be invariably adhered to. The crops, likewise, which will receive the premium, it is stated, will not be the greatest; but those which are raised at the least expense. We dissent entirely to this condition, as its direct effect will be to discourage effort and cultivation. The great object of all premiums in regard to crops, should be to see how much can be produced on an acre; and the whole method and expense of cultivation being detailed, any man can then judge for himself whether the increased crop will pay the increased expense or whether such cultivation be profitable. But in the other case, by the above rule, a premium may in fact be given for negligence and parsimony. An application was made not long since to an Agricultural Society for a premium on a crop of grain, as well as we can remember, where the applicant rested his merit in getting a large yield without having applied any manure, without having ploughed more than once, and without having bestowed only the most superficial after culture. That is, he wanted a premium for the natural fertility of his soil, which was not due to himself; or in other words, he wanted a premium for having done nothing, which can hardly be recommended by the Society as the best mode of improving agriculture. To determine the comparative profitability of crops, an entirely different set of premiums and rules should be instituted.—Ed.

Woolen Rugs for Manure.—About 20,000 tons of these are annually consumed by the farmers in the South of England. They are said to warm the land. The good effects extend to the second year.—Johnson.

Rod Cedar.—If the lining of drawers in which cloths are kept is made of pencil cedar, no moths or other destructive insects will get into them. This wood is cheaper than wainscot or mahogany, and gives an agreeable perfume to the cloths.

Condition of the English Farmers.

DEAR SIR—In my communication published in the July number of the Farmer, I attempted to establish two points, viz: that the climate of England is more favorable for agricultural purposes than that of this country; and that the farmers of England do not fare so poorly as the letter of S. W. would lead us to suppose. In proof of the latter position, I quoted from a recent publication of Wm. Howitt. You are quite correct in supposing that he is not describing the every day life of farmers, for I gave another quotation in which he says "such is a specimen of the festivities of what may be called the middle and substantial class of farmers; and the same thing holds in degree to the very lowest grade of them." As this description holds good, in degree, from the highest to the lowest class, I mean of farmers, so does it, in degree, from their days of festivity to their every day fare. Now you must not suppose, that, in giving Howitt's spirited description of the good cheer of an English farm house, I was advocating the introduction of similar extravagance amongst our farmers. I was only attempting to prove that the English farmers were not reduced to that miserable diet described by S. W. The farmers alluded to are, I grant you, many of them merely tenants, not like ours, freeholders, owning from one to two or three hundred acres of land, but surely this makes my case stronger. At any rate, I cannot agree with you that it is fair to draw a comparison between the substantial freeholders of this country and the laborers of England, whose only wealth consists of their daily labor. It is neither the climate nor poor living, which induces the English farmer to leave the land of his birth, and his early associations, to seek a home in a strange land. I am satisfied that in no other climate can man and beast endure an equal degree of labor and exertion with so little fatigue; and I am equally satisfied that no class of men need live on better fare than the English farmers. There are many other circumstances too, in which the English farmer has a decided advantage over us; he has at all times a market at hand, where he can get cash for his produce. Every farmer lives within reach of two or three towns where weekly markets are held; if he wants to buy stock he knows where to go for it, and if he wants to sell grain or produce of any description he knows where to take it; and is sure to meet with competitors ready to pay the value in cash, so that when he has payments to make, he can provide for them without any sacrifice of property.

I have said so much in favor of England as an agricultural country, that I fancy I hear you exclaim, "if this be a true picture, why leave it?" Wait, and I will tell you. You have, as yet, only seen the bright side of the picture, let us reverse it, and what are all the advantages and conveniences above enumerated, when we find on the opposite side the tithe man, the excise man and the tax gatherer? The last named functionary has his hands constantly in your pocket: the other is peeping about to see that you do not convert your tallow into candles, your barley into malt, or gather the hops which are growing wild on your fences. But the visits of these gentlemen are as nothing in point of injustice and vexation when compared to the visit of the tithe man. To give you some idea of the working of the tithe system, I will instance the parish in which I lived. It was the custom to take the tithe on a seven years lease, the rector appointed the valuer, and we had the option of taking them at his valuation, or suffering them to be collected in kind. We always chose the former as the less vexatious of the two. You will perceive that on this plan the best farmers had to pay the highest tithe. On one occasion, we were rated at 9s. 3d. stg. per acre; produce was high when the valuation was made, but it kept

falling, so that we had a very hard bargain. We presented a remonstrance to our rector and petitioned for a reduction, but his cool answer was, "No, when I consult a physician, I take his prescription." Meaning, that having employed a person to value the tithes, he would abide by his judgment. We certainly could not complain of any injustice in this decision, because if prices had risen in the same proportion we should not have been called upon to pay any more. But the hardest feature of our case was, that we had to pay him whether we went to his shop for physic or not. He drew between two and three thousand pounds per annum from the parish, and had all the duty done by curates for about £200 per annum. We never saw the rector except for a month, which period he was compelled by law to reside on his living, but he made it a month of Sundays, for he came on the Saturday night and left us again on the Monday morning after the fourth Sunday. Is not such a system as this enough of itself to drive a man from his country, let that country, in other respects, be ever so desirable to live in?

I recollect seeing a letter from an English farmer who had emigrated to this country. Did he express his joy in finding a climate and fare superior to what he had left? No! he commenced his letter by thanking God that he had found a spot of ground where priest had never set his foot, and showed all through his letter a spirit of exultation at escaping from the grasping rapacity of the tithe man.

Yours, &c.

B. M.

Climate and Productions of England compared with the United States.

MR. COLMAN—Your correspondent B. M. comes down upon me with a wet sail, for giving the preference to the climate and agricultural products of the United States over those of Great Britain.

As he very gravely asserts that "English horse beans are equal to our Indian corn for all feeding purposes," I shall leave him alone in the glory of his argument, and confess that I was in "error" when I gave the preference to the agricultural productions of the United States over those of England. But to show that I did not speak without book, and that I had some authority for my "error," I quote the opinion of an English master in rural economy. Capt. Barclay, in his agricultural tour through our country in 1841, invariably extols our soil and climate in the most elaborate and even extravagant terms, while he is very general and unparing in condemning our want of skill, and slovenly neglected system of agriculture. To account philosophically for our defects, he charges them directly to the overflowing bounties of our superior soil and climate; he says "where nature is bountiful man is invariably indolent." In England, where nature gives less, men are more provident and industrious. Struck with admiration at the luxuriant Indian corn in the neighborhood of Philadelphia, where it was grown for feeding cattle and horses, Capt. B. frankly admits that the cultivation of our "corn entirely supercedes the culture and use of other green crops as food for stock."

In equinoctial America, where the cereal grains and tropical fruits alike abound, Indian corn is almost the only bread stuff of the country. Humboldt tells us that there is but one plant, growing from the earth, which yields as much food to man; the plantain (*Musa paradisiaca*) is supposed to yield more nutriment off a given space of ground; but its various adaptation as food for man and beast, bears no comparison to the Indian corn.

In Spain, Portugal and Italy, Indian corn is cultivated to a great extent as food for the poorer classes, and I here once more venture to repeat, that if Great Britain, by some inversion of nature's laws, could be

favorable with our warm, stimulating sun, so that the soil would grow Indian corn, we should hear no more of her hungry population feeding on bread made "damp mouldy grain."

B. M. takes a narrow view of our extended growing region, when he says "that in a good season other crops suffer;" a large crop of corn common with other grain is very general in Ohio, Indiana, and in other states south and west. The present season with us, is called favorable for all crops except corn, and yet at this time, 20th July, we are here on the "Seneca level" the Dutton corn in full bloom, with all the cereal grains on the eve of a dundant harvest.

S. W.

Condition of Ireland.

The subjoined interesting letter should have been given sometime since; but was accidentally overlooked. It will not fail, however, now to be read with pleasure; and we have strong hopes that it may be followed by others.

Dublin, December 14th, 1841.

M. B. BATEMAN—

Dear Sir—I little dreamed two months ago this day when we were at the Fair in Alexander, that I should be in so short a time in the old world. But so it is, although I cannot realize that I am so far from home. Steam has almost bridged the Atlantic, and brought the two worlds to be near neighbors. Three weeks' day I was in New York, and I have been nearly a week in Ireland.

My visit to this country is one of business as well as pleasure, and I shall see all that can be of use or interest to a practical man. I shall make myself familiar with their methods of putting up their beef, pork, as well as butter. I shall examine their cattle, sheep and horses, and see their mode of feeding, and if so that I am blessed with a safe return my own dear country, I shall be able to tell our farmers all that is worth knowing upon these subjects.

I have already filled many pages with notes upon these points, which at a more leisurely period may be condensed or elaborated for the public. I trouble myself very little with viewing old castles or remarkable ruins. They do well for the tourist who wants to spend his time and make a book. The living present is my object, and to that I mainly lend my efforts. Although I have been so short a time in the country, yet I have not been an idle spectator. I have seen some of their best farming country, and their best stock.

Some of the country is very fine, especially a portion of that passed through on the route from Cork to Dublin. To me it has a very odd looking, though pleasant appearance. The fields are generally small, the greater part being from three to five English acres, divided by hedges and ditches, which at this season do not present a very cleanly or snug appearance. I suppose in summer they look much better, though proprietors complain very much that the poor people cut down the trees and brush during the winter for fuel. The soil is good generally, and the climate, though varied.

Winter wheat for the last three years has been very uncertain crop, and the prospect now is that it will be shorter next year than was ever known before. All grain or spring crops grow remarkably well, I give an abundant return. At one time Ireland was to export large quantities of wheat and flour to England, but now she imports more wheat than she exports. The corn factors account for it, by the increased production at home, owing to the great attention attending its cultivation, and the farmers turning their attention more to grazing, which is very profitable owing to the immense demand for all kinds of stock for export, and an increased demand at home, getting out of the improved condition of the people:

temperance movement having done more to regenerate the country than any thing else. It is a very uncommon thing to see any man drunk. I have seen but one man yet in all Ireland that was the worse for drink. So that if they can, by any means, employ their people, Ireland must become a very independent state. I think as soon as it has been fairly tested that property is safe, and the people wish it, manufactures will flourish at once, and soon become a great source of wealth.

The weather, both here and in England, has been wet beyond any thing ever before known. It has rained almost constantly for the last two months. Thousand of acres are all ready for the seed, yet they can get no opportunity to sow their winter wheat, and much that has been sown will rot in the ground. Nothing but a miracle can save them from a short crop another year. Potatoes have not been as productive as usual, and it is so wet, a great many are yet to be doing. To add still more to the misery of the people, the wet weather has prevented a great many from laying up their usual supply of turf for fuel: peat being the chief dependence of large numbers. The prospect ahead for the poor is indeed one of unmingled blackness. Yet the splendid mansion overlooks the humble cabin, and the rich and luxuriantly living proprietor, cannot feel the misery of the ill-fed and half clothed cottager, though a tenant of his wide domain. Oh, ours is indeed a glorious country, and we are blessed above any other people. May we ever be mindful and duly thankful for those blessings, the half of which we cannot appreciate without seeing the misery and degradation of the people here in this old world.

Sincerely yours,

T. C. PETERS,
of Darien, Genesee Co., N. Y.

Useless Complaints.

To the Editor of the New Genesee Farmer:

As this is my first attempt to spread my ideas before the readers of the Farmer, the meanness of my essay may require some apology. I live in a portion of the Union where the paper is but poorly patronized, either by subscription or contribution. Most of the essays which fill its columns, are either from the pen of the editor himself or from those of correspondents living in the same latitude in New York, New England, or the western states. Not long since, two copies of the paper made their appearance at our post office with no definite address, and though they bore no other written message than the word "distribute," I thought this in common with their being sent might be construed to mean considerable. It might signify that the Genesee school of agriculture wished to edify us Marylanders; or that they would know what we were thinking and doing; or that the Farmer desired our support; or, perhaps, all these things together. I would not be the one to undertake the cause of my neighborhood with the New Genesee Farmer, were it not that I supposed there were no other likely to do it. It is true I have some ideas not just of a local nature to communicate, but these I could whisper to that able correspondent, who might present them in a more attractive garb. Consequently, if my friend Colman thinks my remarks would be unprofitable to his readers, he may keep the edification to himself.

It is a common thing with the farmers of this part of Maryland and our neighbors of Pennsylvania, to be making continually complaints about the weather. It may be that you Yankees are less ungrateful and more philosophical on this subject than we are—that you do not foolishly torment yourselves with viewing only what is gloomy in every picture, but make the best of things beyond your control. If happily this be the case, and my remarks could be thought uncall-

ed for by the state of affairs amongst you, I hope you will send us a luminous lecture on the subject in some future number of the Farmer. I shall take great pleasure in presenting it to my neighbors, that they may see I am not alone in maintaining that it is unreasonable as well as unchristian, to complain that our weather is not better. The religious farmer, who is thus inclined to murmur, I would remind of the debts he owes to a kind Providence. The farmer who does not allow obligations to a superior being to occupy much place in his affections, I would remind of the unhappiness he brings upon himself by his proneness to find fault with the weather.

Upon taking a view of the past and this much of the present year, I do not find that heat and cold rain and sunshine, could have been more happily blended in our climate to promote the whole happiness of man. Produce of most kinds comes forth at our cell in abundance, the air has been healthy and pleasant, and yet thus fraught with blessings as it is, I can hear scarcely any thing respecting the weather but a torrent of invectives. Because an occasional frosty night endangered the blossoms that had put forward prematurely, "It is the coldest spring I ever saw." When just a plenty of rain, with a temperature the most agreeable to all who have been cursed to wear clothing, was nourishing with the utmost vigour, or when wheat, oats and grass, "It is bad weather for corn,—the cut worm will have half of it." When the thermometer rose to 80° and 90° and we had a little moisture, quite necessary to prevent things from parching, "Won't this foggy weather be apt to rust the wheat." When, just at hay time and harvest, the rains were suspended for a month together, "I am afraid the corn crops will be short." Now, while the most agreeable vicissitudes of wetness and warmth are forcing our green crops to a most luxuriant growth, almost every farmer who meets me exclaims "What a bad time to harvest." Should this essay meet the eye of any one who has been tempted to such remarks as these, I beg him to consider that should the weather be really accessory to the evils here mentioned, if his care cannot avoid them, how foolish to be troubled about it! If, on the contrary, his management might have averted the bad effect, let him blame himself not the weather.

Such, of late years, has been our progress in knowledge, that the weather is almost the only thing tangible, whose laws we have not reduced to our own administration. J. P. Espy and his compeers may investigate and theorize, but if they contemplate controlling the winds and clouds, I despair of their success. Nor is it to be desired. This control of the elements is one of the essentials of success in farming, which the Creator has reserved to himself. He has promised that "seed time and harvest, cold and heat, should continue" to the end of the world, and hitherto he has verified his word. So auspiciously has he ordered the elements in our favored climate, that we are actually groaning because of our abundance. How unreasonable and impious then to complain! Instead of murmuring, let us be thankful we were not doomed to toil to bring water from the clouds as well as bread from the earth. To the kindness of Providence are we indebted that this additional burden with a thousand more, were not imposed upon us. The receiver of alms has not the shadow of right to choose, and since fruitless murmurs about what he receives can only embitter his condition, it is both wisdom and virtue to be content with our lot.

Since I commenced this article, the 7th number of the current volume of the Farmer has come to hand. An editorial on the first page entitled "Political Anomalies and Inconsistencies," is excellent. In these times of silly complaint, it is a perfect dainty in senti-

ment. Fellow farmers, consider that article. If you have any thing to say about it, I would like to hear it. I would say something myself, but am too near the end of my sheet.

I must yet notice an article on "Noxious Weeds," on page 103 of the late number. I object to the term "noxious," as I have yet to learn that a single plant that has come from the Creator's hand is "noxious." It is true, the sacred historian seemed to consider "thorns and thistles" as an inconvenience, when he speaks of their growth as a consequence of man's disobedience; but since the earth does produce them, we might as well just make the best of it. We have found that thorns make very convenient fences, and to some parts of the world it would be a real loss to part with them. As for thistles, just look at the fair side of T. Tuff's account, on page 105. How much better for his brother's land, that those Canada thistles absorbed from the air a fund of nourishment for some future crop, than if, while its owner neglected it, no "noxious weeds" had taken possession. Continual cropping would exhaust any land, did not a growth (of "noxious weeds") spring up in the intervals of culture, to replenish its fertility by their substance which is not thought worth gathering. Friend Colman, I have not room for more, than to say; but I hope the subjects I have hinted at, will receive more ample justice from able pens. Thy patron,

L. BALDERSTON.

Cecil County, Md., 7th mo., 1842.

For the New Genesee Farmer.

"Spare the Birds."

A sort of skirmish has been going on for some time past between the advocates of the birds on one hand, and the friends of unmangled fruit on the other; the one maintaining that all the depredations of the feathered race on the products of their orchards are immensely overbalanced by the hordes of pestiferous insects they destroy; while the others say that the good they do is greatly overrated, and that even those insects which they do eat, are more commonly of the harmless kind, the more destructive affording not quite such delicate morsels, and as a consequence remaining untouched.

Now all this contention would much better become the mode of philosophical inquiry adopted by philosophers of former centuries, who tried to investigate the operations of nature by abstract reasoning in their closets instead of observation in the open air.

"They could tell what time of day
The clock would strike, by Algebra."

and some of them even went so far as to get into long and angry quarrels whether two angels or spirits could actually occupy the same mathematical point at the same time!

Common sense teaches that when any thing is to be ascertained in the natural world, the right way to do it is by direct observation and experiment not by splitting hairs and dove tailing syllogisms. If you want to know which way the wind blows, why, go out doors and see; or how many bushels of wheat you have to the acre, measure it; argument and guessing will not avail much. So with the bird controversy; instead of battling it out on paper, resort to direct examination. Watch their operations, and see what they eat; dissect their stomachs and see what they have swallowed; and let not hasty examination suffice. The experiments must be repeated, and repeated, and repeated,—in all seasons and at all places; and then we shall not work in the dark, but know which are our enemies and which our friends; which are devouring the noxious and which the harmless insects; and properly estimate the pleasures of their singing, while we are sighing for the loss of our fine fruit which they have just swallowed. J.

We publish the following Circular with pleasure, and hope that all interested will give it their particular attention. The silk culture is certain to go forward. The public mind will presently recover a healthy state in regard to it. We want the results of actual experience—facts, accurately observed, clearly stated and fully authenticated; then no man who puts his hand to the plough need look back. We have had moonshine and Jack-o'-lanterns enough; mystification and impositions in abundance; now let us proceed by the clear light of day. As a branch of domestic husbandry it is sure to afford an ample reward to labor.

SILK CIRCULAR.

To Silk Growers in New England.

Gentlemen—At a Convention of Silk Growers, held in Northampton, on the 10th Nov. last, it was unanimously

Resolved, That, as during the infancy of the Silk business, great practical benefits may be expected from periodical meetings of its friends, a committee be chosen to consist of one from each of the New England States, whose duty it shall be to call a Convention at such time and place as they may deem expedient, to be called "The New England Silk Convention."

Thereupon, I. R. Barbour, Oxford, Mass., Dr. P. Brownell, East Hartford, Ct., David Benedict, Esq., Pawtucket, R. I., Dr. Artemas Robbins, Bellows Falls, Vt., Calvin Messenger, Newport, N. H., and Luther Severance, Esq., Augusta, Me., were appointed as this committee.

In pursuance of the purposes contemplated above, the subscribers say, that they design to invite a meeting of Silk Growers at some central place, the early part of the ensuing autumn. In the meantime, it has occurred to them, that, by an early attention to the matter, a great amount of valuable information connected with the Silk Culture, may be collected as the results of feeding the present season, and embodied in the form of a *Statistical Table* to be laid before the Convention and the public.

It is cheering to know that the results of the past summer's operations have been generally decidedly encouraging, that the aggregate of the Silk Crop in Massachusetts, shows nearly a *three fold* advance upon any preceding year,—but this is probably about the ratio of increase in the other States of New England, and throughout the country,—that public confidence, after the late revulsion, is returning to the business, and that the Silk Culture is extending itself as rapidly as correct information respecting it is diffused; in giving promise that it will soon become fully established.

To secure this important object, all that was wanted by our intelligent and enterprising men, is, *facts*, *facts*—well attested *facts*. The results of feeding in 1841, could they now be all collected, and embodied so as to give a *Tabular View* of the whole matter, would, it is fully believed, at once satisfy any business man, in regard to the *entire feasibility* of the Silk enterprise, and that it profits, when rightly conducted, far greater than in other branches of ordinary farming. Let us, then, be prepared to give to the public these facts, next autumn, in such a form as to command the confidence of business men. Do we not owe this small service to ourselves, to our country, and to the unborn millions that are in future times to be clothed, and fed, and educated from the fruits of this interesting form of agricultural industry?

For this purpose it is only necessary for each one engaged in the business, whether he does much or little, to keep such records as will enable him to answer the following questions—

1. How many seasons have you fed worms?
2. What quantity of land have you fed from the past season?
3. How old are your trees? (If they are of different ages, give the average.)
4. How many lbs. of cocoons have you made, weighed as they are gathered?
5. What has been the expense of making the cocoons here reported?

These questions can all be answered in figures. For a note of estimating expenses, see below. In addition to these questions, there are a few others which we suggest.

1. What kind of trees do you use?
2. Have your trees been essentially injured by standing out winters?
3. Do you head down your trees in the spring?
4. In gathering foliage, do you cut up the bushes?

5. What kind of buildings do you feed in? and how well ventilated?

6. Do you give your worms any artificial heat?

7. Have you ever fed in an open place, like a shed, or corn barn, where the worms had a perfectly pure air? If so, state the results very particularly.

8. Do you use air-shedded lines upon your worms?

9. Have you failed in any part of your operations the past season? If so, state the cause and circumstances.

These points will be all that is essential to the purposes designed, though we shall be thankful for any remarks or facts bearing on the general subject. To give expenses by some uniform rule, we suggest the following simple method. Make a little book, in which, at the close of each day, to enter the number of hours employed by men, women, and children. Then consider the labor of able bodied men at 10 cents per hour; women at 6 cents; boys and girls between 15 and 17, at 5 cents; between 12 and 15, at 3 cents; and under 12, at 2 cents.

The expense of planting trees, we wish to be given by itself, as that is not an annual expense. Give us also, the fair rent of the buildings used, and we have all that is wanted.

That we may have time to prepare the contemplated Table in season for the Convention, we wish to have the returns all sent in by the 15th of September. To every person furnishing a return, free of expense, a copy of the table will be sent. Direct to I. R. Barbour, Oxford, Mass., post paid.

I. R. BARBOUR,
P. BROWSELL,
ARTEMAS ROBBINS,
CALVIN MESSENGER,
LUTHER SEVERANCE,
DAVID BENEDICT,

Committee.

March 24, 1842.

P. S. The Committee design to send this circular to every Silk Grower in New England. But many of course will be overlooked, because unknown to them. Will you, therefore, show this to all in your neighborhood, and get as many returns as possible. In Massachusetts, returns cannot be less than 500 cocoons of some sort. In New England probably not less than 2000. From all these establishments we would hope for full returns, in due time, and free of expense. All Silk Growers are equally interested in the object aimed at, and the committee, as such, have no funds.

10,000 PEACH TREES.

For sale by the subscribers at their Nursery, (near M. cedonville on the Erie Canal,) all of which have been propagated from BEAUMONT TREES, whose genuineness or excellence has been thoroughly proved. They are of fine and very thrifty growth, and have all been at least once transplanted, and the roots thus greatly improved for again re-planting, so that the danger of loss or even check in growth from this operation, is exceedingly lessened. Price 25 cents each, \$20 per hundred, \$150 per thousand or \$160 well packed and delivered for transportation.

THEY ARE THE CHIEF VARIETIES, which will afford a constant succession of fruit from early in 5th mo. (Aug.) till late June ripening according to the order in the list. EARLY ASSAULT—fruit small, good, tree of slender growth. EARLY TOLBORN—fruit medium size, excellent; a good bearer, and a most valuable early peach.

LARGE RED RABBIT—fruit large, excellent. Ripens ten days later than the preceding.

EARLY YORP—large, sweet and rich; a fruit of the highest character.

WHITE IMPERIAL—large, white with a red cheek, sweet, juicy and melting, and most excellent peach obtained probably from the celebrated Noisette, which it excels.

YELLOW ALDERBROOK—fruit rather large, one of the finest yellow peaches—very juicy and white young.

SEABOARD—fruit large, red, of first rate excellence.

RED CHEEK MALACOTON—fruit rather large, be. useful, of fine flavor, ranks as first rate among yellow peaches—bears well.

HILL'S CHERRY—a very large, fine, yellow peach.

LATE YORP—an excellent freestone peach, except in unfavorable seasons.

HEATHY PRING—when not too cold in diameter, sweet and excellent.

Orders directed to Thomas & Smith, Macedon, Wayne Co., N. Y., will be promptly and faithfully attended to and the trees, carefully packed, sent by the Erie Canal, or by the Auburn and Rochester Rail Road. J. J. THOMAS—Macedon, 6th mo. 1, 1842. W. R. SMITH.

Complete pedigrees will be given. Terms liberal. Particulars next month. Easy Lake transport.

SALE OF SHORT HORNS IN CANADA.

A VALUABLE lot of High Bred Durham Bulls, will be offered for sale by auction, on Tuesday, OCTOBER 15th, next, at Dundas W. Flanck, Canada.

Complete pedigrees will be given. Terms liberal. Particulars next month. Easy Lake transport.

PLOUGHS.

A NEW AND IMPROVED KIND OF PLOUGH, (of any size) designed for breaking up summer fallow, may be purchased at the Rochester Eagle Furnace,—price \$6 and \$7 each. Wood and other produce taken in exchange.

A. J. LANGWORTHY.

June, 1842.

BUFFALO NURSERY.

THE stock now on hand for sale is much larger than at any former period, embracing a large collection of the most valuable kinds of the Apple, Pear, Peach, Plum, Cherry, Quince, Strawberry, Apricot, Elderberry, Strawberry, Raspberries, Gooseberries, Currants, &c.

Of Ornamental Trees, Flowering Shrubs and Plants, a fine assortment, comprising a glutinous and desirable article in this department.

A full stock of Green-house Plants. I also offer for sale 25,000 Apple Trees of one year's growth from the Gr. fr. or Queen Anna, in autumn will average 12 bushels of fruit. The cost of 120 of the most valuable kinds—four-fifths of which have been taken out of bare-root trees and consequently will soon produce fruit. They will be sold for cash at the low price of 85¢ per hundred.—No less than 75 to 100 of any one kind to be taken.

Also 5,000 seedling trees of the true English Mazzard Cherry, at 85¢ per 100. Orders, per mail or otherwise, will receive prompt attention. Trees or Plants packed in superior order and shipped at Buffalo on board of any steamboat, vessel or canal boat required. Catalogues gratis to every applicant. Buffalo, Aug. 1842. B. HODGE.

Important Sale to Agriculturists.

IMPROVED SHORT HORN DURHAM CATTLE. On Thursday morning, 8th September, at 10 o'clock, will be sold, at the exhibition ground of the Philadelphia Agricultural Society, Rising Sun, on the Germantown Road, 3 miles from the city, a choice selection of splendid Durham dairy stock from the herd of James Gowen, Esq., of Mount Airy, consisting of imported cows, bulls, and calves from Dairy Maid, Pocahontas, Victoria, &c., and by the celebrated bulls Colostris, Prince of Wales, and Leander.

This sale will afford to breeders an opportunity of adding to their stocks thorough bred animals of high character and pure blood, and their diffusion into proper hands is a primary object in this sale, together with the necessity of a separation of the herd to prevent cross breeding.

Catalogues will be ready in due time, and the cattle may be examined at the exhibition ground two days previous to the sale. August 1.

Remarks on the Weather from August 26th to September 25th.

Aug. 26th and 27th, gentle showers; 28th, foggy this morning; 29th, fair and continued so to the end of the month.

September, the seventh month from March, which was formerly the first day of the year.

Sept. 1st, fair; 2nd, cloudy morning—cleared off in the afternoon; 3d, cloudy; 4th, fair during the day, but rain at night; 5th, fair and continued so until the 8th; 9th, rain; 10th, fair; 11th, thunder shower early this morning, also this afternoon and evening, and very rainy through the night. 12th,

cloudy; 13th and 14th, fair; 15th, rain—a powerful shower this afternoon at 4 o'clock; 16th, rain—cleared off towards night; 21st, a very windy day; 25th, a little frost this morning.

The month has been warm and wet; the rain gauge has shown a fall of water equal to 5.15 inches.

The mean temperature of the first day of September, was 80.16 degrees; the highest this season.

Note.—The planet Mercury may be seen Oct. 8th, 25 degrees and 7 minutes east, angular distance from the Sun.

Farmers' Holidays!

This is the month in which most of the Fairs and Cattle Shows are held, and every farmer should attend one or more of them. In addition to the list given on page 159 of this paper, we mention the following for the benefit of more distant readers.

Queens Co. at Hempstead, L. I., Oct. 13th.

MASSACHUSETTS.

The Hampshire and Hampden Society will hold their twenty-fifth Fair and Cattle Show at Northampton, Oct. 12th and 13th.

Worcester Co. at Worcester, October 12th.

Plymouth " at Bridgewater, " 12th.

Bristol " at Taunton, " 12th.

MAINE.

Kennebec Co. at Readfield, Oct. 12th and 13th.

Cumberland Co. at Gray's Cor. Oct. 19th & 20th.

The Fair at Albany.—The Albany Argus says,—

"The entire affair went off admirably. A great and generous spirit of emulation pervaded the Fair, in all its departments, and its vast and varied displays, producing results surpassing the expectations of its most sanguine participants."

Sale of Short Horns.—Our readers in Canada and the West, will notice the advertisement in this paper of a sale of thorough bred cattle to take place at Dundas, on the 15th inst. We have seen some of these animals, at the residence of the Hon. Adam Ferguson, and take pleasure in stating that they are among the most perfect and beautiful specimens of Durham Short Horns we have ever witnessed.—*Pub. N. G. Farmer.*

Butcher's Meat in England.

One of the most celebrated cooks in Europe, and the favorite of distinguished Sovereigns, gives the following opinion:

"Butcher's meat in London is fine, and yet it has not the unctuousity of our meat in *potages*, sauces, and *consommés*. The cause is in the climate, and in those perpetual fogs which deprive the pasturage of a part of their nutritive juices, by keeping them too green."

American Toast.—"The ladies—the only endurable aristocracy, who rule without laws, judge without jury, decide without appeal, and are never in the wrong."—*Eng. paper.*

Crops in South Venice in 1842.

Mr. ENRICH—Having given the readers of the New Genesee Farmer an account of the crops grown annually in this town, since the commencement of your valuable paper, (the New Genesee Farmer,) I continue the practice.

Wheat.—The crop in this vicinity is not very good; the rust has injured it so that the crop will be very light this season. The wheat, however, is somewhat better than some persons anticipated it would be, a few days before harvesting. Those that have threshed for seed, find it better than they expected; but on an average, I think there cannot be much more than half a crop grown in this town.

Corn.—The crop will be light this season. There are, however, some fields of corn that have the appearance now of being pretty good. The cold months of May and June were injurious to the corn crop; so much so, that many farmers ploughed their corn up and intend to sow wheat. If the frost should keep off through the remainder of this month, there will be some very good crops of corn; but on an average the crops will be exceedingly light in this quarter.

Barley has done well this season. The crop may be considered a good one.

Oats have done very well too; I think I never saw better oats and more on the ground than were sown this season.

Peas are extraordinary good; far better than last season. As a great many were sown this season, therefore, farmers will have enough to fatten their pork without depending upon their crops of corn.

Flax is good, and a great deal was sown in this town, expressly for the seed. Flax is not manufactured much into cloth in this vicinity, other goods being cheaper and which answer the same purposes for wearing apparel.

The Potatoe crop will be a middling crop. The drought in July and August injured them somewhat, but there will be enough for our own consumption.

Spring Wheat.—There was not much sown in this neighborhood; however, what little was sown came in very well, and better than the winter wheat.

Roots.—There are but few roots grown in this vicinity, and what few there are are not very promising. Fruit is very scarce in this region of country; there will be, however, enough for our own use if carefully husbanded. The fruit is very inferior. Owing, no doubt to the cold weather last spring. Under these circumstances, we have great reason to be thankful to Him, who has given us in sufficiency and abundance these comforts and necessities of life.

South Venice, Sept. 19th, 1842. W. S. T.

Swiss Cows in Harness.

We took a drive yesterday up the most romantic valley, and met two peasants driving their cow in a little cart. They stopped to offer us some peas. I particularly remarked the cow, to see if working did her any harm; she was in excellent condition. I wish the cottager in England would adopt this custom; it never comes into his head that the cow can do anything but give milk. We know nothing of economy in England; what is daily wasted in it would save from starvation the miserable creatures who die in the streets. But what is every body's business is nobody's and so those who can afford it go on allowing waste. —*Lady Tarasour's Last Tour and First Work.*

[Translated for the New Genesee Farmer from the German.]

CHANGE OF SEED.

BY PROFESSOR SPENGLER, OF GOTTINGEN.

Occasional change of seed is unquestionably of the highest importance in agriculture. Observant farmers have doubtless remarked that, though all possible pains be taken to secure the best and most perfect seed grain, it is generally more advantageous to procure a supply from some other and distant section of country.

In the year 1811, I obtained a parcel of multicolored rye from Friedland in Bohemia—a celebrated rye district, having a clay soil. This rye, thus brought a distance of 21 miles, was sown in a sandy soil, rich in humus, which had been manured by ploughing in a green crop of vetches. It vegetated well, grew astonishingly, and attained a height of from 9 to 2½ feet, with heads proportionally long—measuring from 9 to 10 inches, and containing from 115 to 120 grains each. In the ensuing fall I sowed some of the rye thus produced, on a soil of similar character and equal quality, manured as before by turning in a crop of vetches. The stalks, however, scarcely attained a height of 7 feet—which was the more remarkable, as, in the summer of 1812, the season being peculiarly propitious, all the other rye in the vicinity was unusually tall. When sown again, the following season, this rye produced stalks averaging only 5 feet high; and the heads were proportionally shorter and less productive, in each year. The deterioration of this rye was rendered the more obvious, as, in the year 1812, I procured some fresh seed from the original locality; seeded it on land of similar quality, after plowing in vetches as before, the stalks of which grew to the height of from 8 to 2½ feet—contrasting strongly with the more stunted growth of the other.

I have experienced similar results in the cultivation of buckwheat, oats, barley, beans, potatoes, and flax. With us, the stalks of Indian corn, also, from seed imported from the southern part of the United States, attain a height of 15 or 16 feet, the first year; but the product of the second seeding will not exceed 10 feet in height; and in the third year, it will not be taller than our domestic corn.

On many soils a frequent change of seed appears to be essential, for various reasons. It is undoubtedly true that the seed can only produce a vigorous and perfect plant, when its germ is adequately developed; and it is equally certain that such a development can result only from a proper commixture of the ingredients of a soil, aided by the influence of climate, seasons, &c. But the success of the plant is determined also, in a great measure, by the kind of nourishment afforded to its earliest germs and radicles. Hence, when seed grain, having a perfect germ, is supplied, seasonably and in due proportions, with those substances which contain, in an assimilable state, the peculiar *pabulum* or nourishment which the infant plant needs, it will grow vigorously, and flourish permanently to maturity if the soil continue subsequently to furnish a proper supply of the requisite food. A field recently manured with fresh stable dung, it is well known, will not produce good seed grain; and hence it is probable that the good or bad quality of seed grain depends on the presence or absence of certain ingredients of soils. Grain grown on land recently manured with animal dung, contains, according to Hermbstadt, more *gluten* than that grown on lands not so manured; and where the land was manured with sheep dung, the grain produced is peculiarly rich in gluten, because this kind of manure contains in abundance the nitrogen essential to its formation. Now such grain is probably unsuited for seed, precisely because it contains too great a quantity or proportion of gluten, whereby the starch of the seed

grain is too suddenly decomposed. Whereas, were a less proportion of gluten present, the starch would be gradually converted into sugar—the earliest food required by the developing germ. We may, therefore, conclude that, in general, all grain is unsuited for seed if it contain a very large proportion of gluten, or of other nitrogenous substances capable of converting starch rapidly or suddenly into sugar. But in grain intended for breadstuffs, this over-proportion of gluten is a very desirable quality; because the more of it any grain contains, the better it is adapted for producing flour—gluten being among the most nourishing substances.

Experienced farmers know it to be very advantageous to sow, in a sandy soil, rye grown on clayey or aluminous upland. The reason appears to be this, that the rye from clay soils contains only the due proportion of gluten. On the contrary, it is found to be improper to sow rye from rich, moist, bottom lands on sandy soils; because the seed contains such an over-proportion of gluten as to convert the whole of the starch suddenly into sugar, and the sugar as suddenly into other substances not congenial to the germinating plant. Sandy soils in general do not furnish good seed grain, inasmuch as such grain is deficient in certain substances—as lime, magnesia, &c.—essential, nay, indispensable, to the perfect development of the germ. That sugar does, in fact, play an important part in the germination of seeds and the first development of the plumule and radicle, is manifested from the fact that all the minute seeds, parsley, carrots, &c., germinate better if steeped for a few days in a solution of sugar or in a diluted syrup. But though sugar is unquestionably of great importance in the germination of seeds and in the earlier development of plants, I do not maintain nor assert that the successful issue of the process is the effect, exclusively, of this substance. On the contrary, I am convinced that, to secure a propitious result, the presence also of alkalies, sulphates, and chlorides, in due quantities and proportions, is absolutely requisite.

There are soils which imperiously require an annual change of seed. But it is, in most cases, sufficient to procure a supply from places in the immediate vicinity, or not more than three or four miles distant—a circumstance which the principles above indicated will serve to explain.

Climate also has a very conspicuous and important influence on the quality of seed grain; and experience teaches that, for seed, such grain is best suited as was grown in a colder region or district. Chemical analysis shows that such grain contains a smaller quantity of gluten than that grown in warmer climates. Wheat from the North of Europe contains much less gluten than that from the southern coasts of the Mediterranean.

The deterioration of grain, so as to become unfit for continued seeding, I have most frequently observed in oats. But I remarked, in every instance, that the soils which produced bad seed oats were deficient in lime, magnesia, or some other substance or ingredient requisite to the full development of the germ. Oats invariably become unfit for seed if sown in soils deficient in lime or potash; and chemical examination shows that good seed oats contain much lime and potash. Now, though we may, from these and similar circumstances, deduce in part the reason to what change of seed is oftentimes necessary, it is not to be doubted, for the full elucidation of this matter, more numerous experiments and observations are desirable. Probably results highly satisfactory could be arrived at if good and bad seed grain, as well as the soils on which they respectively grew, were subjected to accurate chemical analysis.

The great benefit resulting from frequent changes

of seed, is particularly striking in the culture of flax; it being well ascertained that seed imported from Russia is greatly superior to that of domestic growth. Russian flaxseed, though commonly an ill-looking, unpromising article, invariably produces a much longer stalk and fibre than native seed, apparently much better. That climate likewise, in this case, exerts an important influence on the due proportionment and admixture of the ingredients of the seed, may be considered certain. But what the ingredients really are which contribute to, or effectuate, the more vigorous growth of flax from Russian seed, remains to be ascertained.

Again, by means of seed grain, climate may in some cases, and to some extent, be transferred from one region to another. Thus, if we sow, in a colder climate, seed oats from a warmer district, where oats ripen early, the plant will, in its new locality, mature at an earlier period than the domestic oat, though not so early as in its native region.

Finally, it may be considered as an ascertained fact, that soils chemically ill constituted, require the most perfect and best seed grain. A judicious selection will, in such cases, very materially increase the quantity of the product—the difference being in some cases not less than fifty per cent.

From the National Intelligencer.

The Polar Plant of the Western Prairies—a Vegetable Compass.

WASHINGTON, August 9, 1842.

Dear Sir—In offering through you to the National Institution a dry-pressed specimen of the *Polar Plant* of the Western Prairies, it is proper that I should give a description of it, and of its location. It is a species of fern, with one large flat leaf, whose plane always points to the north and south. The leaf is symmetrically disposed about the stalk. It attains the height of from ten to sixteen inches, and it is believed that it never blossoms. It is spread profusely in large beds over all the Western prairies, from the far Northwest to the far Southwest. It has been seen in the prairies of Wisconsin and other regions east of the Mississippi. It is never found in the forests; or, in other words, out of the prairies. It has been well known to the hunters and trappers of the West, and to the officers of dragoons; but I believe that its existence has never (at least extensively) been made known to the world. Its plane is always in the plane of the meridian, when not disturbed by high winds or other external causes. The indications are always most accurate in the valleys, where the beds are sheltered from the winds, and where the traveller finds them arranged in parallel positions, faithfully pointing out the direction of the meridian. The leaf is symmetrical, and thus there is nothing in its indications to distinguish the north from the south.

The specimen which I send was plucked from the prairies near Fort Gibson, west of Arkansas.

That its indications are actually the same wherever found is the universal testimony of all who have known of it; and I have met many who have noticed it from south of Fort Towson to a considerable distance north of Fort Leavenworth. In many instances those who spoke of it derived their first intimation of its existence from that excellent officer and capital woodsman, Capt. Nathan Boone, of 1st regiment U. S. Dragoons, son of the celebrated Daniel Boone.

The cause of the polarity of this curious plant yet remains to be discovered. Being symmetrical in shape, or rather the weight being equally distributed about the stem, it is possible that its sap or fibre is so thoroughly impregnated with certain salts of iron as to be deviated, from the period of its infant growth, by the action of the magnetism of the earth, turning like a compass needle on its stem or root as a pivot. That it is not caused by the action of light would seem probable from analogy, as vegetables acted upon by light are noted for turning their leaves or blossoms towards the sun instead of from it. At mid day the plane of the Polar Plant passes through the sun, and thus it shuns the light. I have noticed it in long-continued cloudy weather, and could find no alteration in its position.

As the existence of the torpedo and the electrical eel exhibited the influence of electricity on animal life, this plant is very interesting as showing its probable connexion also with vegetable life; thus furnishing a link to supply the chain of gradation. It is well

own that there are many distinguished naturalists and professors of physiology who would go higher even to the human frame, and predict the final discovery of the intimate connexion between electricity and the operation of the nervous system. Any connection with the action of electricity or magnetism (as supposed to be one and the same agent) is now generally interesting, when there are so many ingenious minds throughout the world devoted to such investigations.

I have ascertained to my satisfaction, that this plant has been well known to trappers and to many of the Indian tribes, and that they have been in the habit of utilizing themselves (in their tours over those vast tracts) of this humble but omnipresent guide, which a kind Providence has sprinkled over that region, and which is thus available in cloudy weather, when the sun and stars are denied them. Even if it is granted that it is less needed by the red man, no one will deny its uses to the whites in a country destined still for a long period to be roamed by hunters, traders, pioneers, and other white men.

I will here add that Captain Bonn also states that there is spread all over the West a certain root, called the "snake root," whose juices are very grateful to quench thirst, and which is found in the greatest abundance in those parts of the prairies which are high, dry, and most likely to be deprived of water in a season of heat and long drought.

It is needless to descend upon these beautiful and striking examples of the wise provision of Nature, furnishing a vegetable compass and the means of quenching thirst, ever ready for the wanderer, and which located in a region destined perhaps for the long time to come in the history of the world to be occupied by a roving population.

I am, with high respect,
Your obedient servant,
BENJ. ALVORD,
Lieutenant United States Army.
To F. MARKEE, Jr., Esq.,
Corresponding Secretary of the National Institution.

For the New Genesee Farmer.
MANURE.

The first step which a farmer takes towards successful business, is to understand the value of manure. And, as he discovers the value, he uses all the means in his power to increase the quantity. The fact is, if very farmer who owns a hundred acres of good land, and who manages his manure according to the usual practice of the country, were to use the very best means which he possesses for its manufacture and application, he would find his pocket-book heavier at the end of each year, to use the most moderate computation at the present low prices, by at least three hundred dollars.

I need not here attempt to show how that the product of the barn-yard may be increased fourfold by the use of wuck or marsh mud and lime properly applied; but my object is to call attention to another source of manure which appears to be even less known and attended to. But I ought here at the outset to caution the delicate and fastidious reader not to follow me any further, as the Editor did some time ago at the close of a similar article, though of course I mention this fact with all deference.

Poudrette is well known to be a very powerful manure, obtained in the neighborhoods of the cities where it is manufactured. But we, away back here in the country do not possess this advantage which our city friends do; and very few have ever thought of manufacturing their own poudrette. The contents of privies, instead of being regarded as of great value which they truly are, are most people look upon as a downright nuisance. Now, if the offensive odor may be removed, at the same time that a valuable manure is made, two very important points will be attained.

I have searched in vain for a particular account of the process employed by the poudrette companies; and in the absence of such account have endeavored to use such means and knowledge as I could lay hold of, and imperfect as the mode may be, it has been of decided value to me, and may prove so to others. The entrance to the privy is well flanked with evergreen trees,

and on one of the other sides which faces low ground, is a passage or road through the trees for a large tight box or trough to be drawn away from under the building, which is placed about two feet above the ground on that side for the admission of the box. A plank door shuts it in closely. Runners are placed under it so that a horse may draw it away by the iron hooks attached to it; low wheels would be better.

All the care required after this, is to sprinkle every two or three days a few handfuls of plaster (gypsum) over the inside of the box from above. This is all. Air-slacked lime, and ashes, are also valuable; but plaster, by furnishing sulphuric acid for combination with the gaseous ammonia and thus preventing the escape of this volatile but powerful ingredient, is considered the most so. Hence also, the use of plaster is found exceedingly to lessen the fetid odor, a matter of no small consequence. Lime also greatly lessens the offensive smell, but by what means I do not know. There ought to be enough of plaster, lime or ashes, to keep the contents of the box in a dry state. When it is full, it is drawn off, spread upon the ground and mixed with the soil, or made to constitute a part of the compost heap.

I have tried only one experiment on its fertilizing power, and that a very indefinite, but otherwise satisfactory one. Very rich stable manure, and poudrette, were applied to different parts of a small piece of ground—the stable manure, according to estimate, being about ten times the bulk of the night soil or unmixed base. The whole was sown with turnips. The result is, so far, that the turnips on the part manured with the poudrette, have made a growth at least three times as great as those on the part treated with stable manure.

Straw from Rusted Wheat.

We give the subjoined communications from a farmer of long experience. We cannot vouch for his philosophy, which is certainly ingenious enough, and may be well-founded; but his facts are valuable; and a small amount of facts well authenticated by observation and experience, is worth a load of theories. We wish our experienced and respected correspondent would let us hear from him again on various subjects, which must have come within his observation; and we beg him here to send us another valuable communication, not to tax himself with the postage.—Ed.

Mr. COLMAN.—In the number of the New Genesee Farmer for September, you ask the opinion of farmers in regard to feeding cattle with straw from rusty wheat. I have had some experience in that way. Let us first inquire what occasions wheat to rust. It is generally supposed the occasion is from a sudden flow of sap to the head at a certain stage of its ripening, which causes the straw or bark of the straw to burst near the heads, and the sap to flow out, and drying on the stalk, it forms the rust. Now this sap is the most nourishing part of the straw, and makes or fills the berry. Flowing on the outside of the straw and drying there, will it not increase the nourishment of it?

At this time, there is very little wheat raised in the valley of the Connecticut; but formerly, when the country was new, there was considerable; large quantities were exported. It sometimes rusted. I always found that cattle ate this rusty straw much better than that which was bright, which led me to suppose that it was better feed; and why should it not be, if it has that which would have filled the berry if it had flowed to it, dried on the stalk? I verily believe that those who have found their cattle injured when fed on this straw, on further investigation, may account for the injury in some other way.

Shrunk wheat threshes with much more difficulty than plump; much of it cannot be readily threshed out; and when there are large quantities thrown out

daily, the cattle picking out these heads, they may be over fed; or this wheat may be put up in too green a condition and become rusty in the mow, which would entirely change the nature of it.

How this may be, I cannot say, but for myself I had much rather have the straw of shrunk wheat when well secured, as feed for cattle, than that which is bright. We never keep cattle wholly on straw.

FROM A FARMER OF CLAREMONT, N. H.

Smut in Wheat.

One word respecting smut in wheat. When I was first acquainted with this country, being a boy, the wheat raised here was all smutty, so much so that it required to be washed before it was fit to use. The first year we sowed the wheat procured in the neighborhood, which was smutty, for seed, the crop was very smutty. The next season some for seed was procured from a distance, clean of smut; this wheat was washed clean, and while wet, as much good ashes was mixed with it as would stick to the wheat, and sown immediately. The crop was clean of smut, and for more than twenty years in succession we practiced the same way on the farm. We procured wheat clean of smut, washed and sowed the seed, and during the whole time never raised a crop of smutty wheat. I have more than once sown beside my neighbor's lot, nothing but a fence dividing us,—he sowed his wheat dry and I as I have stated—his was very smutty, mine quite clean. All this time winter wheat was sown and occasionally spring wheat; and to this time, which is more than sixty years, I never have raised a crop of smutty wheat, when I observed the above rule; or procured wheat clean of smut, washed, &c. Once I had some spring wheat somewhat smutty; and it was from smutty seed. For a number of years of the time I speak of, there was no lime in the country, otherwise lime would have been used instead of ashes, as we have done since lime has become plenty.

A CLAREMONT FARMER.

Killing Flies.

Many persons, like myself formerly, are much puzzled how to get rid easily of these little annoyances. I have been very successful this year, by the use of cobalt, which is indeed no very new thing, but still but practically known. I procured a six-pence worth at the druggists, pounded it fine, mixed small portions on dishes with water only, and placed them upon shelves. During the fly season, which has lasted a month or two, from two to three hundred or thereabouts have dropped dead upon the floor daily, which were easily swept away. How we should otherwise have fared, I cannot tell; but if all that have died in the house had lived to annoy us, we should have been literally blackened with them. As it was, very few indeed were at any time visible.

X. Y. Z.

Evil turned to Good.

A neighbor, who had last spring a field partly overgrown with a dense matting of Stein kraut or red root, (*Lithospermum arvense*), ploughed the whole crop of this pernicious weed deep under the soil, and planted the ground with corn. The corn on this portion of the field is now decidedly superior to the rest, in consequence of the nourishment of the decaying vegetable matter.

J.

Worms in Swine.

Corn soaked in ley, perseveringly used, has cured the disease in swine called kidney-worm, in numerous instances. A neighbor of ours succeeded with it in a very bad case. If breeders would give their hogs plenty of salt and brimstone, they would rarely be troubled with diseases.—Dollar Farmer.

ERRATUM.—In our last number, in the communication of S. W., page 141, in line 15 from top, for American cotton read foreign cottons and fabrics.

Agricultural Excursion in the Genesee Valley Concluded.

FENCES.—The fences in this part of the country are chiefly worm fences, formed of chestnut or ash rails; and in most cases ten rails in height. A mode of constructing a straight stone and rail fence which prevails here, deserves remark. In this case small stones of the size of a man's fist to that of a cocoa nut or much larger are gathered, wherever they are to be found, and laid up, beginning with a width of two and a half feet at bottom, and gradually drawing in towards the top until they reach a height of about two and a half feet. Morticed posts are set in the wall about ten feet asunder, and two sawed rails finish the fence. But it is most worthy of notice, that in order to prevent these small stones, many of which are round, from spreading or falling down, small flat pieces of wood about the size of the staves of a pail or barrel, and of various lengths, are pretty freely interspersed among the stones; and operate effectually as binders. Such a fence is not only tidy but strong; and stones are used and cleared from the field, which it has been generally found difficult to dispose of, and which have commonly been buried, or spread by the road side to disfigure or encumber the road, or left in unsightly and inconvenient piles in the field.

The want of timber for fencing must presently be seriously felt, and a worm fence, the common fence in the country, occupies a great deal of room. Another strong objection to a worm fence is, that the angles, not being reached by the plough, are commonly secure harbors for weeds and rubbish of various descriptions. In some cases I saw small pieces of hedge of the white thorn, thrifty, clean and close, and in a condition to satisfy me that there would be no hindrance to its cultivation. The common thorn of the country would make a good fence, and is easily propagated. I believe that the beech would make an effectual and durable fence, and its rapidity of growth recommends it. An intelligent English farmer of Canandaigua, whose good management of his farm entitles his opinions to much respect, states that he has seen beech hedges in his own country, which were every way to be commended. They bear trimming well and have no enemies. The white thorn is liable in the older parts of the country, to be destroyed by the borers, which infect the apple and the locust trees; and also to be girdled by the field mice under the snow in winter.

FARM BUILDINGS.—The houses in general are of wood. Here and there is occasionally met with the log-house of the pioneer; but in most cases these have passed away; or if not removed, are converted into lumber houses or sheds; and their place is supplied by neat frame buildings of one or one and a half story in height. The first edition is coarse and unsightly; and seems not in keeping with the clean and cultivated fields around it; but the second often marks a great advance, and appears with embossed covers and gilt edges. The power of habit and of naturalization in these cases often strikingly illustrated, as the "old folks" of the family look back with strong yearnings to the "log cabin" where they first fixed themselves. They are often free to confess that some of their happiest hours were passed in these homely beginnings, when amidst many severe privations and hardships, they were cutting themselves a passage through the dense forest for the admission of light into their unglazed dwellings; and beheld the mighty trees, like a retreating army, falling year after year under their victorious advances; saw the virgin wilderness, which had hitherto been untouched by the hand of civilization, now gradually pouring out its rich and golden treasures for man and beast; perceived with a proud consciousness of new wealth and power,

the rapid increase of their white woolled flocks without and their white haired urchins within door; and resting from their labors at the close of day, at the door of their humble wigwam, saw the smoke of many a neighboring cabin slowly curling upward to the skies, heard the lowing of returning herds, beheld where so lately the stately pine towered above the forest in sombre majesty, the vane of the village steeple like a new star sparkling in the beams of the setting sun, and the triumphs of civilization and improvement every where spreading themselves, as the morning's light is seen scattering the shadows of night and causing the wide landscape to become resplendent with beauty.

There are some brick houses; throughout the country clay is abundant for making bricks; and a fashion has been introduced of building with cobble or small round stones. In this case the window and door sills are of hewn stone, and so likewise are the corners; and then the walls are carried up with these small stones, commencing with a thickness of wall of two feet in the cellar, a foot and a half in the lower story, and gradually reducing it to a foot in the upper story. These stones are laid in a strong cement of lime; and these walls are cheap, durable, and handsome.

Many of the houses throughout the county are built in good taste, and a commendable regard is paid both in the villages and in retired situations, to embellishing the places with trees, shrubbery, and flowers. The locust is cultivated with great success. In these respects I know no parts of the country to be compared with what of Western New York I have seen. This speaks exceedingly well for the character of the inhabitants, for their intelligence and refinement. So far as my observation goes it does them no more than justice, for without disparagement to any other section of the country, and my examination has not been restricted, from what I have seen I do not believe there is to be found a more intelligent, cultivated and improved people, than the rural population of Western New York, a people of better manners or of better morals.

Nor do I believe that Heaven ever placed men in circumstances of more substantial comfort and prosperity. The soil is of extraordinary fertility and of easy cultivation; the climate salubrious, for the intermittent fevers, which formerly prevailed, are now of rare occurrence; the scenery in the rolling or hilly parts of the country, picturesque and beautiful; ready and cash markets are always to be found for the great staple of the country. There are extraordinary facilities of communication by railroads and canals; good common schools and advantages of education by means of seminaries and academies of the best character, and numerous colleges for obtaining, at an expense which puts it within almost every one's reach, the best and most improved education, ornamental and useful.

These are great blessings. If we estimate a man's prosperity by a pecuniary standard, we may find situations in which, by the chances of trade and speculation, men may sooner grow rich; but, if by a far wiser and truer standard, we determine their prosperity by the substantial means of comfort with which they are surrounded, and their advantages for social enjoyment and intellectual and moral improvement, then it would be difficult to find situations more favored.

PRICE OF LAND.—The price of land may be said to vary from 40 to 60 dollars. I speak now of improved farms. There is comparatively a small amount of forest land to be cleared. The land is in many cases in the hands of large proprietors, who do not care to sell and prefer leasing their farms. In some cases leases for a short time, say of a year only, are preferred to longer leases; and with a view to deter-

mine the rent, the general cultivation is prescribed, the probable or practicable return of every piece of land on the farm is estimated, and the rent calculated accordingly. This seems to be an equitable mode, and certainly more satisfactory than naming a gross sum, calculated upon the nominal value of the whole farm. The rent is expected to be paid in cash, not in kind. Short leases, where a change of tenants is likely to take place every year, would be prejudicial to both parties; but where the landlord is willing to renew the lease upon favorable terms to a faithful tenant, and encourage him in making improvements, short leases are better both for landlord and tenant.

The most remarkable sale of a single farm that has perhaps ever occurred in this country, took place in Groveland, in Livingston county; where, as I understood, one hundred thousand dollars in cash were paid for 1800 acres of land, and this was for only one half of the farm of the individual, who sold the estate. The buildings upon it consisted only of a brick house and some barns; but the buildings were nothing more than decent, and these were perhaps some log cabins upon the place. This price a little exceeded fifty dollars an acre, and the estate was bought by the community of Shakers, not for speculation, but for residence and occupation as a farm.

The fact of land in this county being held in very large parcels by individuals, has undoubtedly impeded its settlement and improvement. I certainly do not complain of those who hold it, for I know no reason to question the perfect legality of their possession, and the equitable management of their estates. Nor do I know of any scheme by which property could be generally equalized short of revolution, nor, if even by that fearful remedy, it could be equalized, how by any possibility it could be kept one hour, after the division had been effected. I am likewise as strenuous as any one in maintaining the unquestionable right of every man to the fruits of his own labor, and to the disposition, so far as is compatible with public order and good morals, of those proceeds according to his own pleasure. But I confess myself so far an agrarian as to think that the earth itself, the soil, the very foundation and means of human subsistence, should never be exclusively claimed or appropriated or parcelled out to the prejudice of any, who are disposed to cultivate and improve it, and that it should never be held as matter of mere traffic or speculation separate from the improvements which are made upon it. I could wish that the amount held by any individual should be restricted, that no man should ever be at liberty to possess that which he does not use nor improve; that the fee of the land should always remain in the state; and at the death of an individual should revert to the state, the state always being held bound to make a just and liberal allowance for improvements made upon it, or any increase of its value through the skill or industry of the man who had it in his possession. These notions, I am perfectly aware, will be held by most men as mere dreams and moonshine. Let them go as such. I regard them as purely speculative, and in the present condition of society, how well soever they may be founded in natural right, their realization never likely to be approached. They are altogether utopian. Those who have the property are too strongly entrenched in law and custom and mutual interest, to fear any change, and those who have it not, may make themselves quite contented with the present arrangement; for there will be no alterations for their accommodation. A society or community established upon principles of strict equity and justice, is little more than a mere fiction of the imagination, nor as yet likely to be realized upon any large scale even under the clearest sunshine of the gospel. Even the rich national domain, which ought to be regarded as the great leg-

ney of the people, and held sacred for the rising millions that are yet to demand bread from the earth, is, in the natural course of human rapacity and authorized abuse of power, to be covered with the mere paper titles of men, who never saw it, and care nothing for its improvement, who lie down upon it like the dog in the manger, while they or their heirs are to be made rich by the increase of its value, although to its intrinsic value or improvement they have never contributed and never design to contribute the worth of a straw.

I have already extended my remarks upon this excursion to a much greater length than I had intended. There are many topics connected with it, which I wished to have discussed at large; but this could not be done to my own satisfaction unless I took the whole paper to myself; and this would be little to the satisfaction of my subscribers; and very likely to leave the whole concern, both editing and subscription, to myself.

I wished to have discussed at large the Improvements of which I think the husbandry of the country is capable. Its agriculture, though respectable and productive, is yet in a very imperfect condition. Crops of wheat, the great product of the country, averaging only about twenty bushels per acre, and of Indian corn not more than twenty-five or thirty, are little more than a third of what the soil can be made to produce. I hold that the only limits of production, which should ever satisfy the enterprising and intelligent cultivator, are the capacities of the soil; and the only limits of cultivation are, the relation which the value of an article, when produced, bears to the expense of its culture. The capacities of the rich soil have as yet by no means been fully tested; and the various questions, what products would best compensate for the cultivation, and whether the most expensive cultivation would be warranted, and whether with the present prices of land and of labor, it is better to cultivate a large extent imperfectly or a smaller extent much more thoroughly, and various other matters growing out of these, are all questions, the proper decision of which involves so many and such various elements, the price of land, the cost of labor, the facilities of market, the supply, the demand, and a variety of particular circumstances connected with the particular localities and likewise with the domestic condition of each farmer, that I cannot now enter upon them. At present I must reserve these topics for some other public occasions; and in the mean time I beg leave to suggest them to my intelligent correspondents, hoping they may excite their wits and then, as matter of course, move their pens.

I am unwilling to close this very superficial sketch of the agricultural condition of the Genesee Valley, without acknowledging, as I do most respectfully, the kindness and hospitality with which my visits were welcomed by many of the intelligent farmers of this favored region. I shall retain a grateful recollection of it as long as I live; and be most happy to accept their kind invitations to extend the acquaintance. I deem it among the greatest blessings of my life that my taste and pursuits have led me to cultivate a most intimate acquaintance with the rural and agricultural population; and some of the happiest hours of my life have been spent at their cheerful firesides and under their hospitable roofs. I have heard much of the vulgarity and boorishness of the country; but they do not belong more to the country than to the city. True politeness consists in the habitual disposition and endeavor to make those around you happy. It is not, as many suppose, a matter of mere form and manner, but of feeling and sentiment. Among different classes or conditions of society, certain conventional forms are agreed upon under which it is to be expressed; but in cases, where form are most studied,

it too often happens that forms are all which are regarded. The genuine and substantial disposition may be discerned under a rough as well as a polished surface, and expressed in the most natural and awkward as well as the most graceful and studied attitudes and movements. An old friend of mine, in giving an account of his early life as a candidate for the ministry, told me that the kind woman with whom he boarded where he first settled, in helping him to a piece of hard-boiled Indian pudding, a frequent dish upon the table, was in the habit of cutting it into her hand and laying it in his plate; and with the spirit of a truly benevolent philosophy, he added, that "as I knew her hand was as clean as her heart was pure, I was willing to receive it in any way she chose." Yes; and so it should be to every mind that knows of how much more value is the substance than the shadow, as if it had been handed upon a silver fork or porcelain cover, protected by a napkin of the finest damask. I can say in truth that among the hundreds, I may say thousands, of farmer's families, which I have visited, I have never witnessed the slightest rudeness or incivility; and have in most cases experienced a politeness, as sincere, as genuine, and as refined in character, if not in form, as in the most brilliant and carpeted halls of city palaces.

A considerable portion of the inhabitants of this favored region have enjoyed the highest advantages of education; and to the charms of rural life add the best refinements of polished society, without, as is too often the case, destroying the simplicity of the country by the burdensome and, in the country we may safely call them, the frivolous formalities of city etiquette. When in such residences, to the rich abundance of the products of a well cultivated farm and garden, you find united a disposition for rural labor, a taste for rural scenery and rural sports, and the beautiful accomplishments of music and drawing throwing their charms around, and all mingled with a hospitality as frank, sincere, and unrestrained as it is profuse and elegant, and "books and work and beautiful play," dividing the hours, and the character and mind are found in a corresponding harmony, it is difficult to imagine any earthly condition more favored.

I might give names in these cases, for I know my description may awaken some curiosity; but this would be contrary to all my habits, and as inconsistent with my own sense of propriety as it would be offensive to the delicacy of friends to whose kindness I owe so much enjoyment.

The natural scenery of many parts of the Genesee Valley is of surpassing richness and beauty. The view of the valley from Mr. Wadsworth's residence and from the eminently beautiful residence of Mr. Murray, on the summit of Mount Morris, in its verdure, its luxuriance, its forests, its single trees, and its numerous clumps of trees left here and there with exquisite taste, in the windings of the river, in the numerous scattered residences, in the bright villages seen in different parts of the valley and sparkling upon the summits of the hills, presents a landscape of extraordinary magnificence.

Following up one branch of the valley to the villages of Nunda and Portage, to the upper Falls of the Genesee, the road traverses a comparatively new country, but one destined to be extremely rich in its agricultural productions. At the passage of the Genesee river down the Falls, and through its high cliffs the traveller of taste will find a treat, second, as far as my observation has extended, only to the wonderful and glorious Niagara. In the course of about two miles the river makes a descent, in three successive leaps, of nearly three hundred feet, and in a full state of the water, these falls combine in the highest measure, the elements of beauty and grandeur. The riv-

er has worn its way for a distance of several miles through very lofty cliffs for a long extent, of four hundred, and in some instances, of seven hundred feet in height. The whole passage is perfectly unique in its character; and while it charms by its picturesque, it produces a profound impression of awe for that mighty power which, by a steady operation for successive undefined periods, has carved out this mighty channel for these ever rushing waters through the solid rock. The traveller here, likewise, has a view of the great artificial tunnel of eleven hundred and ninety feet through the mountain, for the passage of the Genesee Valley Canal. This is a great enterprise and a work of immense labor; but standing along side of the deep gorge of the mountains, the mighty work of thousands of years, one can only exclaim, what are the works of man compared with the works of God!

Improved Stock in Genesee County.

Mr. COLMAN—I assume the liberty of calling the attention of those engaged in rearing fine stock, as well as those wishing to improve theirs, to the extensive herd of Peter A. Remsen, Esq., consisting of Durhams, Herefords, (or a cross of Durham with the Devon), the rest of various grades, amounting in all to 156 in number. He commenced his stock by direct importations from various herds in England in 1834—his Bull Volunteer, a white, was out of the stock of Mr. Coling; his Bull Alexander, a red, was out of the stock of Mr. Maynard of Harsley Hall, Yorkshire, Eng., and of as good pedigree as England can boast. I have it in my possession back to the famous Bull Hubback. Mr. Remsen resides one mile east of the village of Alexander, and any person wishing stock will, by calling on him, find him courteous and affable, willing to go into the minutest detail and at once ready to set prices upon his stock in unison with the times. Any person calling upon me can see a sample of his stock in the Bull "Red Jacket," which I purchased of him soon after I came here. He has been fed only on hay and grass, and he will raise the beam 2000 pounds, being only 3 years of age past; he has been let to 100 cows this season, and I have had to keep him in my poorest feed, as his disposition for fattening seems equal to Hubbacks.

I commenced improving my stock of cattle some 35 years since, from the imported stock of Messrs. Adcock & Mason, of Otsego Co., called by them I believe the Bakewell, which stock I continued to improve until a Devonshire Bull was brought into the country, from whence I came, and thinking a cross of my Bakewell with the Devon would succeed, I commenced breeding from that stock, and found the result most highly satisfactory, and continued in that course till I removed hence. I am now breeding, or rather commencing, a stock from pure Devon cows and my bull Red Jacket, and from present appearances I am satisfied with my course.

I cannot close my remarks without offering a suggestion to the various Town Committees of the Genesee County Agricultural Society, which is, that the members of each town committee should visit in person every farmer in their respective towns, and earnestly solicit their aid and membership to said society, and I think we should have but little fear; for when once fairly enlisted in a cause so worthy, the society must flourish, and not present such a scene as was the last year, by a deficit in means sufficient to draw the sum apportioned to this county from the state.

I am, sir, yours with regard,

ZACHARIAH CONE.

Batavia, Sept. 9th, 1842.

Remark—Having on several occasions visited Mr. Remsen's farm and admired his fine stock, we take pleasure in publishing the above notice, and can assure our readers that both owner and cattle richly merit all the praise bestowed.—*Pub. N. G. Fair.*

TRANSACTIONS OF THE NEW YORK STATE AGRICULTURAL SOCIETY.

The next paper in the Transactions is the Report of the Corresponding Secretary. This does great credit to his intelligence, zeal, and industry; and give him claims upon the grateful acknowledgments of the friends of Agricultural Improvement throughout the State. In all such cases as the trust undertaken by him, two things are particularly important; the first a clear conception of the work to be done, and second, all due diligence and perseverance in its accomplishment. In these respects the Secretary deserves all praise.

We have room for only a single quotation.

"The undersigned may be permitted to remark that he deems it one of the first objects of the State Society, to collect and disseminate information in relation to the most approved methods of conducting every process of husbandry, on the different soils, and under the varying circumstances which most necessarily exist on a territory so extensive and diversified as that of New York. To note also the gradual changes and improvements which annually occur in its different sections, and to make them the property of the whole, is also an important branch of our duties. The unprejudiced observer who turns his eye back thirty, or even ten years, will perceive that changes of great magnitude have taken place. Nor has the skill of the husbandman yet reached its height. Science is daily placing new resources at his command, and pointing out to him potent and unsuspected agencies which, for the want of a proper knowledge of them, have lain dormant within the reach of his hand. Chemistry has consented to become his handmaid; and geology at his bidding unlocks the secrets of the earth. Mathematics has wandered from the schools to teach him to construct the utensils of his labor; and zoology has made known her laws, to enhance the value of the flocks and herds who feed and clothe him.

The agricultural periodicals of the day are doing much to disseminate and equalize, among our farming population, the light which is flowing in from so many quarters. It is the duty of the State Society to take the lead in this effort, and to stamp permanently on its archives every progressive step, which attends the advance of agricultural science. In conclusion, the undersigned takes occasion to reiterate the hope already expressed by him, that the agriculturists of our State, if again called on to contribute their assistance to an undertaking of this kind, will evince as much zeal as they possess ability for the task."

AGRICULTURE OF CAYUGA COUNTY.

Two letters on the Agriculture of Cayuga County are next given. We should be glad to insert the whole, but must limit ourselves to some few quotations.

"The principal improvements in this county consist in draining, manuring, and the use of clover and plaster as a preparation for wheat. Our intelligent farmers generally drain each field sufficiently, before breaking up for wheat or corn. The increased product pays the expense in two or three years.

The beneficial effects of plaster consist chiefly in producing a large growth of clover. If this be suffered to fall, or be trampled down by cattle after it has attained its full growth, the land will generally produce a large crop of wheat.

The soil is generally a dry loam. The west, central, and part of the northern and southern sections contain considerable limestone. A part of the northern sections is sandy, with little lime. The hilly parts before mentioned, are nearly destitute of it.

The principal products of the calcareous parts of the county are, wheat and wool. Considerable quantities of pork and beef are also sent to market; the larger portions from such parts of the county as are deficient in lime, and therefore not adapted to the culture of wheat.

For wheat, naked summer fallows on swarded land, are generally used by our best farmers. In most parts of this county, the crop ought to be sown as early as the 1st of September, and the land should be clean and rich. It has been proposed to sow wheat after one ploughing of grass land. This might answer on sandy soils, but on clay, the soil would remain inert, obstruct the wheat roots, and furnish little nutriment to the young plants. Frequent ploughings cause the soil to absorb from the atmosphere substances useful to vegetation.

Barley requires a rich, clean soil, and the more thoroughly it is pulverized, the better. It should be rolled before the last ploughing, and thoroughly harrowed in. Oats are usually sown on stubble land after once ploughing. Spring wheat is but little cultivated where I reside. Until our land can be freed from Canada thistle, charlock, &c., the three last mentioned crops ought in my opinion to be cultivated as little as possible.

I would say to my brother farmers, drain thoroughly, cultivate less land, keep less stock, and never go to the expense of ploughing and sowing, until your land is in such condition as to afford a prospect of a remunerating crop. To new beginners I would say, imitate those farmers in your neighborhood who obtain the best crops."

"The condition of agriculture in this county has materially changed within forty years. The town in which I settled was a wilderness, and all that was necessary was to clear off the forest, and we obtained from thirty to forty bushels of wheat per acre.

Our present condition is different. We obtain now, rarely more than twenty bushels per acre. The decrease is owing to the manner of cultivation. Many farmers have been in the habit of planting their lands to corn, or sowing to oats, peas, barley, &c., in the spring, and after taking this crop off in the fall, immediately sowing to wheat; after this, peas or barley; thus taxing the land beyond its power of production; while others, who have pursued the more judicious course of sowing clover after wheat, and rotating their crops, are still getting from thirty to forty bushels per acre, if the season be favorable.

The soil of the most part of this county is peculiarly adapted to wheat, especially the southwestern part, in the vicinity of the plaster beds. Whenever we sow this crop in this region, if we sow after clover and use the plaster freely, we seldom fail of obtaining from thirty to forty bushels per acre.

The most judicious method, I think, is to sow to wheat in the fall, and the following spring sow from six to eight pounds of clover seed to the acre, with, perhaps, one and a half bushel of plaster. The next season after taking off the wheat, mow the clover the last of June, and plaster well immediately after, then the second crop of clover will start in time to fill well with seed, which will answer to mow early in September; from which crop, we get from six to eight bushels of seed per acre. The next spring after the taking off of the seed clover, we either plough and plant to corn, or let it remain and secure another crop of clover, about the middle of July; after which, we plough and sow to wheat. Frequently, however, before sowing to wheat, we roll the ground, and after letting it remain a few weeks we go over it with the harrow and cultivator, which well pulverizes the surface of the ground. The long tap root of the clover makes a fine dressing for the wheat.

Often of late, after sowing our wheat, we cover the ground from one to two inches with straw, which keeps the ground moist and protects the tender wheat from the spring frosts.

With respect to the best method of fattening cattle, I consider one bushel of flaxseed worth more than four bushels of corn, if properly prepared. I will give you

my method. I put six quarts of flaxseed into a five gallon kettle, and fill it with water, then hang it over the fire in the evening and let it simmer (not boil) all night. Set it off in the morning, and you will have a kettle full of jelly. With five or six quarts of this jelly mix the same quantity of shorts or meal, which an ox or cow will be exceedingly fond of, after eating of it few times. Any one will be convinced of this who has been accustomed to feeding oil cake. If the oil cake is worth three shillings per bushel after extracting six quarts of oil, what is the seed worth in the pure state?"

The agriculture of Cortland County is next noticed.

AGRICULTURE OF CORTLAND COUNTY.

"This is comparatively a new country. Within half a century it was one dense forest. The land which now sells for fifty dollars and more, were purchased for less than five dollars. We see in almost every part of the county evidence of well directed effort in the cultivated fields, comfortable dwellings, out-houses, public buildings, temples, seminaries of learning, and above all district school houses, which are the glory of our country. The general aspect of the county is uneven, though not mountainous. There is, properly speaking, no waste land in the county; no large bodies of water; no barren mountains, sterile plains or sunken swamps. The hills are capable of cultivation to their summits, and afford some of our finest grazing land. The county is remarkably well watered.

The soil best adapted to cultivation is a deep gravelly loam, well adapted to the production of grain crops and grass, the three great staples of agriculture produce. The state of agriculture in the county is such as might be expected in a new country. There are some well cultivated fields, but no well directed system of agriculture prevails. Many fields have been under the plough for a number of years in succession producing annually small crops of corn and other grains.

The most important question remains to be answered, viz: what agricultural changes are requisite?

A well directed system of convertible husbandry by which I mean a judicious rotation of crops, and proper attention to the making and application of manure. The annual production of all our tillage land may be doubled in a very few years, and the intrinsic value of the soil greatly increased.

An acre of good tillage land in Cortland county with thirty loads of long manure on a clover or grass ley, and properly cultivated, will produce eighty bushels of corn with as much certainty as forty in the common way, after other crops, and without manure. After corn, the root crop can be cultivated to great advantage, and without any detriment to the succeeding crop of spring grain, and after roots the ground will be in perfect order for the succeeding crop. After roots, sow spring grain, wheat, barley or oats, and sow grass seed and plaster with a liberal hand; and for two or three years you may expect three tons of good hay to the acre, and at the expiration of that time a good grass ley for an other eighty bushels of corn.

The culture of roots, in a stock county like ours, is of great importance. Cattle may be well wintered on any kind of coarse fodder, such as cornstalks or straw with a small portion of roots daily, better than they can on hay alone. Every farmer must adopt that system which best suits his soil and circumstances."

The agriculture of Dutchess County is next reported, in a very condensed and business like manner.

AGRICULTURE OF DUTCHESS COUNTY.

"The present state of agriculture is favorable, much improvement having been made of late years.

Dutchess county has some broken and rugged lands, but the aspect of the county generally, is very fine.

The soil is mostly gravelly and sandy loam.

The products are beef, pork, mutton, butter, cheese, eggs, poultry, hay, Indian corn, wheat, rye, oats, and wool; the last, is fast diminishing as a staple production.

New and improved modes of agriculture are taking the place of old modes.

The horses are mostly of English descent. Among this blood, the Duroc breed is in highest estimation. The best cross, is considered that formed by the French and English breeds; this gives the horse more constitution and hardiness, and consequently, less liability to disease, as well as greater endurance.

Horn cattle—The Short Horn Durham is preferred for milk and beef, but as working cattle, the Devonshire is thought superior; a cross of the two breeds is preferred by many.

Sheep—Formerly the fine woolled Merinos and Saxons were in vogue; but are now giving place to sheep of coarser wool, natives, Bakewells, and South Downs; the latter varieties being reared more as mutton sheep, which is considered most profitable.

Swine—This animal has been much improved within a few years, by the introduction of the English breeds, Berkshire, Norfolk, &c.

Cattle and sheep are, for the most part, fattened upon grass. More or less beeves are stall fed through the winters, and generally fed upon meal and roots. Some few sheep are also fed for the market during the winter. Swine are generally fattened upon corn, at least, the heavier pork; shoats on boiled feed, milk, &c.

Ploughs mostly in use, are the invention of a man in this county, by name of Chamberlain. Various other kinds are used.

The common square, four beam harrow is mostly used; others of late invention are getting into use.

Hay rake—The revolving rake is preferred, as decidedly the best.

Value of our lands, is from \$25 to \$120 per acre, by the farm; average price, about 60 dollars per acre.

The timber is mostly oak of different kinds, chestnut, hickory, and maple.

A diffusion of agricultural science would lead very much to advance the general prosperity of the county. To this source alone, may be attributed most of the improvements within the last few years."

Next follows the agriculture of Herkimer county.

AGRICULTURE OF HERKIMER COUNTY.

The experiment of Aaron Petrie, to whom we are indebted for the report on this county, in preserving and feeding broom corn to his stock is not new. The family of Shakers at Canterbury, N. H. and others, have long practised it and with great success. So have others within our knowledge.—Ed.

"The principal products here, at the first settlement of the country, were wheat and peas. They were marketed at Albany. Almost any kinds of tillage brought large crops, and little or no attention was paid to rotation. Crop after crop was taken off the soil, without any return to it, except such manure as was actually in the way. The soil of the interior is not so well adapted to the growing of wheat as the Mohawk lands, yet they raised some; but their principal products were barley, and the products of grazing. The barley business became large. Large malt houses were erected in different places, after the completion of the Erie canal, and it was sold to them. The lands of the whole county, with few exceptions, became so exhausted that farming was considered rather an uphill business. About 1820, the dairy business began to attract some attention in the northern parts of the county, (particularly cheese making.) All who adopted it flourished at once.

The principal products marketed in the eastern cities now, are cheese and butter. Among the principal products marketed here are wool, oats, barley, In-

dian corn, rye, hay, beef, pork, mutton, &c. In consequence partly of the large profits of dairying, the exhausted state of the soil, and the ravages of the weevil there has been little wheat raised in this county for several years past. We get our supply from the west. Our distillers and maltsters, have greatly diminished in number, and now import much of their grain from other counties and other States. The present condition of agriculture in this county is rather favorable. It is owing to the accidental improvement of our lands by the dairy business, and the profits of that business, to which our county is peculiarly indebted.

One-half of this county is yet a wilderness, most of which will probably in time be settled; but until the boundless, fertile west becomes nearly filled, settlements here must be very slow.

There is little attention paid to the breeding of horses here. Some years ago, the Archia breed of Virginia horses was introduced here, but experience taught us that a horse that can win a purse at a Long Island race, will not answer for a draft horse. I believe the Duroc and Messenger are the best breeds among us. The favorite breeds of cattle for beef are the Durham; but the general opinion is that they are not first rate for milk. There are comparatively few cattle raised here. In the spring of the year, large droves of cows are brought here from the eastern, western, northern and southern counties, and Canada. They are milked through the summer, and in the fall the oldest and poorest are partially grass fattened, and driven to the eastern markets.

The Merino and Saxon sheep have been the favorites of our wool-growers. The South Downs and Bakewells may now be added to the list of favorites. The Berkshire hogs are the best as yet introduced here, although there are others nearly equal to them.

Neat cattle and sheep are generally fattened for market on grass, and hogs are fattened on whey, potatoes, apples, grain, &c. There is much doubt whether it is profitable to fatten hogs or cattle on grain wholly.

There are several kinds of ploughs in use here. I have never seen any kind that would answer our purpose as well as Clute's old patent cast iron plough, and our plough makers should have continued making them; but they were induced to lay them aside by other patentees, and we must buy what we can get. We use the common three beamed harrow. The patent revolving horse rake is in general use here, but there are a few exceptions among those farmers who are so violently opposed to "improvement," in any of its forms, that they had rather, and do still have their wives and daughters use the hand rake in their meadows.

The general value of the improved lands of this county is from thirty to fifty dollars per acre. Some, however, is sold under thirty, and some, favorably located, over fifty dollars per acre. The prevailing timber is maple, beech, birch, basswood, elm, &c., and we are not without our pine plantings, hickory groves, and hemlock and cedar swamps.

Nothing will so advance the prosperity of this county, as a general agricultural education by our farmers, which we can now only acquire by taking an agricultural paper. Although there is much room for improvements, men will not adopt them until they are convinced, and that can only generally be done through the press. A great deal of the matter in our agricultural journals is not intelligible to the uneducated mind, which discourages their circulation. There is hope, however, that the rising generation, which is being better educated, will work the necessary reforms.

Allow me to mention an experiment of my own. The scarcity of coarse fodder, and the high price of hay, occasioned by the drought of last summer, induced me to gather a quantity of broom-corn stalks: I am now having them tried. We cut them with one of Green's "v" cutters, and feed them to cattle without

any other preparation. We have kept our cattle on them about two weeks, and I have full confidence in the success of the experiment. It may have been tried before, but is new to us here.

Silk Culture.

MR. EDITOR—I am much pleased with the favorable notice you have taken of the progress of the silk business.

I have been four years successfully engaged in producing silk, and am now making arrangements for entering largely into the business in 1843. My cocoonery is 20 feet by 60, two stories high, built expressly for raising silk. I have made 130 lbs. of cocoons the past season, and at a cost not exceeding the state bounty, which is fifteen cents per pound. The profit I shall realize will depend upon the demand for eggs next season, having need all my best cocoons for producing eggs.

I believe the silk culture is now firmly established among us, and only needs a general dissemination of facts, which any silk grower is capable of imparting, to induce the former to engage in this lucrative and pleasant employment. The erection of my cocoonery has awakened in the minds of my neighbors a spirit of inquiry which it is hoped will result in a careful investigation of the subject.

It is believed the number of silk growers will be more than doubled next season. I know of many who intend to build cocooneries, and many more who will begin in a small way, having become fully satisfied that it is the safest and most profitable employment which can engage their attention.

My cocoons are converted into raw silk on a reel of my own construction, which works admirably well. The art of reeling silk is found, after a little practice, to be very simple and easy. It requires a little patience by the inexperienced, but perseverance will soon overcome all difficulties.

A market is already open for cocoons and raw silk in various parts of the country, where the highest price in cash will be paid for any quantity that may be produced. To give you a specimen of what I have done, and to show you this is not "all talk and no either," I herewith send you a skein of sewing silk of my own raising and manufacture, which I wish you to examine, and if convenient, you may show it to your best judges of the article, and then let us hear their decision.

Yours respectfully,

JAMES W. CHAPPELL.

Lima, Sept. 15th, 1842.

We are happy to insert the foregoing, and should be glad to hear from others engaged in this business. Our columns shall in due proportion be heartily devoted to this object, which we believe destined to become a great branch of agricultural interest. The skein of white silk, which accompanied this letter, was very handsome and good. Some merchants and tailors to whom we showed it, pronounced it very good. One very competent judge said it was as good as any Yankee silk which he had ever seen; but that it was not even enough nor strong enough. We cannot expect to reach perfection at a single stride. There is no difficulty whatever in the way of our producing as fine and as good an article as can be made. The goal is already in sight.—Ed.

Plucking the Blossoms of Potatoes.

M. Zeller, director of the Agricultural Society of Darmstadt, in 1839 planted two plots of ground with potatoes. When the plants had flowered the blossoms were removed from those in one field, while those in the other field were left untouched. The former produced 476 lbs., the latter only 37 lbs.—*Farmers' Magazine.*

ROCHESTER, OCTOBER, 1842.

Apology—Disappointment.

This number of the Farmer has been delayed nearly a week, in expectation of giving some account of the Fair at Albany. The editor attended the Fair and was to have sent home a report thereof at the close—but nothing has been received from him, and we conclude that he sent a communication by private hands and it has miscarried. We can delay the press no longer, and our readers must submit to the disappointment, with our promise to make amends next month.—*Publisher.*

Important Notice.

Postponement.—The Monroe County Agricultural Society Show and Fair, to be held at Rochester, notified for the 14th and 15th Oct., instant, is postponed to Tuesday and Wednesday, 25th and 26th of October.

The preparatory meeting is to be held at the Arcade on the 15th inst. by adjournment, attendance upon which is particularly requested.

To the Friends of the Agricultural Press and the Subscribers to the New Genesee Farmer.

The subscriber respectfully announces that he has become the sole proprietor, after the first of January next, of the New Genesee Farmer, Mr. Bateham, the former proprietor, having, through ill health, retired from the concern. At the same time, he will continue the editorship as heretofore. He regrets to state likewise, that hereafter the annual subscription for the paper must be one dollar, payable in advance as heretofore. Yet his regret is not unmingled with satisfaction in the assurance, which he has already received from a great many of the readers of the Farmer, an assurance in almost every case volunteered, that such an alteration would be deemed by them equitable and would meet their active approbation. Possibly the approbation may be universal, and then he will be happy to learn that his regret was uncalled for. This would be a little too good to expect in a world where opinions are so various, where one of the strongest passions in operation in society, among men as well as the *kinder sex*, seems to be to get a thing cheap, and where the fact is too much overlooked, implied in a remark of the celebrated Madame Roland, that "she always heard with pain of any one's making a good bargain, because she knew in that case that some other person must have made a poor one."

This remark is but too applicable to the proprietor and editor of this paper; for to our subscribers, the New Genesee Farmer has certainly been worth fifty cents a year, to the farmers for wrappers and to their wives and daughters for curling papers, if such profane witchery in the vanities of this world has ever crept into their premises, while to the editor and proprietor, at 50 cents, its publication has been a serious loss. Wides as our circulation has been, that sum has not the present year covered the expenses; and without the subscription be increased as is proposed, the paper must go out; for no righteous master will require us "to work for nothing and find ourselves."

We respectfully ask our friends to look at the case with an eye of candor; and to sustain us, if we deserve to be sustained. We promise to do all that we can to merit their good will and their substantial

kindness; and we ask in return little more than the means of saving us from coming upon the county and being cast upon the tender mercies of Mistress Dumble.

We intend that our paper, on the first of January, shall be enlarged, and printed on finer paper and with clearer type; that it shall contain more miscellaneous intelligence of an agricultural nature than it has hitherto done; more information in regard to foreign and domestic markets; a greater variety of subjects connected with rural life and condition; the contributions of some of the best writers in the country whose aid is already engaged, and whose aid we need an increased subscription to secure by some just compensation, without which, we have not the face to ask nor the humility to accept, unless in our greatest straits; and we will spare no pains to make our humble sheet a welcome visitor in every farm house where it is permitted to enter; and that it shall not be regarded as an intruder even in a city parlor. We mean that it shall be, to a certain extent, the companion of the gardener as well as the farmer. We promise that the most delicate hands shall not be soiled by its touch, nor the hardest hand find occasion to cast it by in disdain. Wherever there are fruits and flowers, there we shall try to bring our baskets full decorated with the fairest wreaths which we can contrive. We will speak of the plants of the field, from the cedar that waves his proud head upon Mount Lebanon to the hyssop that climbs upon the wall. "Our talk likewise will be of cattle." We will gather around us the lowing herds and spread out the fleeces of gold. We will go forth in the spring to sow the precious seeds; and rejoice with the farmer at harvest home, when, by the blessing of the Lord of the Harvest, he returns in triumph, bringing his sheaves with him; and if, in doing this, we can so the infinitely more precious seeds of truth and virtue, and show the dignity of honest labor, oftentimes far outshining even in the shade the Imperial purple, and inspire and quicken the love of rural pursuits and rural pleasures; and open men's eyes and hearts to the beauties and glories of God's visible creation, to the abundance, the variety and the ceaselessness of his bounty, we shall be but too happy in the delicious consciousness that we have not labored altogether in vain.

We ask our friends to aid us in this attempt. A life not short has been given, as far as other obligations would permit and justify, to the cause of an Improved Agriculture, and especially to the elevation and improvement of the agricultural and rural classes. In what we have done for this cause we have no regrets and no misgivings. We believe it to be under the blessing of Heaven the cause of human happiness, of good morals, and of religion, and we rejoice in the deeper and still deeper hold which it seems to be every day taking in the public mind.

We extend to all our coadjutors and brethren in the agricultural press the hand of cordial friendship. We do not promise that our paper shall be better than theirs, or even as good as any of them; but we promise only to do our best to make it worthy of being read. Such is the cheapness of agricultural papers, in former times altogether unexampled, that a subscription to several of them would create no burdensome tax, nor occasion an expense which any farmer would find it difficult to save from many useless purposes upon which it is now inconsiderately squandered. Devoted to this purpose, it can scarcely fail to do good.

We ask those of our subscribers, who purpose to continue their patronage, to make as early remittances as their convenience will allow. This post-masters will kindly forward them. To those persons who will act as agents, we promise the most liberal terms.

Our arrangements, when fully completed, will be announced in our next number.

Respectfully,

HENRY COLMAN.

Rochester, 1st October, 1842.

Monroe County Agricultural Society Awarding Committees.

The following is the list of Judges or Awarding Committees, appointed for the Cattle Show and Fair to be held at Rochester on Tuesday and Wednesday, the 25th and 26th inst. It is earnestly desired that the gentlemen will all consent to attend to the duties assigned them, and that they will be present at an early hour on the day of exhibition.

On Horses—Dr. F. F. Backus, Rochester, Abram Voght, Victor, Wm. Read, Wheatland.

On Bulls, Cows and Heifers—Wm. Garbutt, Wheatland, J. Allen Frost, Rochester, Jirah Blackmir, Wheatland.

On Oxen and Steers—Wm. Fixley, Chili, Cornelius De Witt, Gen. T. Brown Wheatland.

On Sheep for Fleeces—Mills Landon, Ogden, Daniel McNaughton, Wheatland, J. H. Robinson, Henrietta.

On Sheep for Carcass—Jacob Thorn Rochester, H. Schenck, Brighton, Benj. Birdsall, jr., Mendon.

On Swine—Jesse Harroun, Ogden, Alfred Fitch, Riga, M. Parsons, Brighton.

On Ploughing—L. B. Langworthy, Greece, Jacob Strawn, Chili, C. F. Crosman, Rochester.

On Butter and Cheese, Sugar and Honey—C. M. Lee, Rochester, Elibu Kirby, Henrietta, M. Garrett, Gates.

On Silk, Domestic Cloth, &c.—Lewis Brooks, Rochester, Caleb K. Hobbie, Irondequoit, Henry Martin, Clarkson.

On Horticultural Productions—N. Goodsell Rochester, H. N. Langworthy, Irondequoit, J. H. Watts, Rochester.

On Non-Enumerated Articles—Alex. Kelsey, Rochester, N. Haywood, Brighton, William Otis, Gates.

Committee of Arrangements—L. B. Langworthy, H. M. Ward, M. B. Betcham, P. Barry.

(For the Winter Meeting.)

On Grain and Grain Crops—L. B. Langworthy, Greece, Abram Colt, Mendon, Henry Calman, Rochester.

On Roots and Root Crops—Wm. Garbutt, Wheatland, Stephen Legget, Henrietta, Zera Burr, Perinton.

At the last meeting of the Society, it was

Resolved, That the awarding committees on animals be instructed to require the competitors for premiums, to give certificates of age, pedigree, food, work, &c., according to the 4th section of the Regulations published with the list of premiums.

It was also *Resolved*, That the President be requested to deliver an address to the Society on the day of the Fair.

Also *Resolved*, That the time of holding the Fair be on the 25th and 26th of October, instead of the 13th and 14th.

Further *Resolved*, That the officers of the Society and members of Town Committees, and others, be requested to meet at the Arcade Hall, Rochester, on Saturday, the 15th October, at 11 o'clock, for the purpose of devising ways and means.

Agricultural Addresses.

This number of the Farmer is issued during the absence of the Editor, and the publisher takes the responsibility of announcing, that, by the request of the several Societies, Mr. Colman has agreed to deliver addresses at the approaching Fairs in the counties of Cayuga, Seneca, Ontario, Monroe, Genesee and Niagara, and perhaps at one or two other places.

*From Colman's Second Report***Experiments and Improvements.**

The improvement of agriculture, as a science and an art, depends greatly upon facts. Experiments, illustrating what can or what cannot be done, are of great value. Farmers object to agricultural experiments, as involving expenditures beyond their means; but an experiment on a small scale, within the means of the humblest farmer, may be as instructive and conclusive, in reference to the point sought to be ascertained, as an experiment of an extended and expensive character. The point to be mainly insisted upon, and that, in which farmers commonly fail, is exactness of observation. Without this, no experiment is of any value. In this matter I have been so often disappointed, that my impatience, I hope, he excused, when I urge upon farmers attempting, or at all disposed to attempt, experiments, to pay the most pointed attention to the mode of conducting them; their progress; the circumstances under which they are begun and carried on; and their actual results.

I believe it must be admitted, that there is no class of men of business so little attentive to exactness, in all their operations; and none more ready to draw hasty conclusions, or to deal in what are mere guesses, than farmers.

I certainly design no disrespect to the farmers, when I give an example of a conversation to which I am too often a party. Indeed I should be almost willing to give offence, if I could by any means induce to more precision and carefulness.

Thus: if I ask a farmer, if he has used lime on his land or his crops? he answers, yes. In what quantity to the acre? he did not measure the lime or the land. Could he see any difference where he limed, and where he did not lime? he limed the whole field equally. Did he apply it with or without manure, single or in compost, or did he apply it to a part of the field with or without manure? he applied it to all parts of the field in the same way. Did he perceive any good effects upon the field thus limed and manured? yes. How were these effects ascertained? did he measure the crop? no, he measured nothing, but he was of opinion that the land was benefited by the application: he thought there was a difference in the result from what would have been, had it not been limed. But was this difference attributable to the lime or the manure? it was all limed and manured alike; but he supposed it was the lime. I might go on, but this will suffice. This is a true account of the manner in which my inquiries are often answered; and shows how what farmers call experiments are often conducted. But can any thing be plainer, than that by such experiments no certainty is reached. Whether any advantage was obtained from liming alone, or liming with manure, cannot be determined, because the field was all served alike, and there were, therefore, no means of comparison. Again; if the crop is not measured and compared with a crop not thus manured, how can it be determined what has or has not been gained? Again; if neither part was served with lime alone, and neither with manure alone, and neither part separately from the part with lime and manure in combination, how could any thing be determined in regard to the comparative value or use of lime or manure singly or in conjunction? Then again, if any thing has been effected, yet, if nothing has been measured, neither lime, nor manure, nor land, nor crop, how can it be ascertained what has been done, and its efficacy or utility is to be accredited to the lime?

I state this case, which is not in any respect exaggerated, to illustrate the difficulty of arriving at correct results solely from the neglect of intelligent and exact inquiry and experiment. But I shall be an-

swered, that it would be too much trouble to be as exact and particular as I propose. This is an answer which an inquisitive and intelligent farmer, if he means to respect himself, will be very shy of giving. In most cases, however, it costs scarcely more pains to conduct and observe an experiment with exactness, than to do it in the uncertain way in which it is commonly done. But in the latter case we may be properly said to determine nothing; in the former we reach the object of our inquiry, which is generally much more than a compensation for any pains-taking it may cost us. But in no matter whatever is knowledge of any substantial value acquired without labor and careful inquiry. We might as well complain that we cannot obtain the harvest without sowing the seed, and tending and cultivating the growth. But the constitution and laws of the divine providence in these cases are inviolable, and not to be turned aside for our convenience or indolence; and as far as concerns man's moral benefit, the benevolence of this unchangeableness corresponds with its infinite wisdom.

For the New Genesee Farmer.
The Orchard.

The cultivation of good fruit is of such importance to the farmer, that it cannot be too often nor too strongly recommended to his attention. I have lately travelled through a considerable portion of the country, and have taken some pains to ascertain the quality and condition of the orchards particularly. I have found many excellent apple orchards, loaded with the finest varieties of fruit, but these would not average one in fifty.

The greatest number are of the most worthless character, and the trees miserably taken care of.—Suckers are growing up for several feet around the trees, and the heads or tops have never been pruned or thinned out. This neglect would in a few years deteriorate the very best of fruit.

Besides the neglect with which Farmers themselves have treated this subject, there are other causes to which the scarcity of good fruit may be very justly ascribed, viz: the peddling of apple trees around the country by persons possessing comparatively no knowledge of fruit culture themselves, and caring as little, if they could only make a profitable business of it. The practice of such persons, I find, has generally been to recommend such kinds, whatever they might be, as they had in greatest abundance.

Extensive frauds have been practised throughout the whole country, by persons who make a business of engrafting. They generally represent their scions as some of very excellent and popular kind, when in fact they know nothing of their character whatever. Scarcely a farmer with whom I have conversed, but has been thus deceived. These gentlemen and their scions are well worthy of notice.

Every person who plants a fruit tree, or propagates one in any way, should spare no pains to get the best kind, and from a reliable source. No confidence should be placed in these itinerants who have no character at stake, for disappointment will be the result in nine cases out of ten.

Pears, plums, peaches and cherries, are ten fold more deficient than apples. There have been very few, if any, good pears in market this season; those that have been brought in, have sold at \$2.25 to \$2.50 per bushel; but you might travel 20 miles in many parts of the country, and not find a single pear tree with fine fruit in use at this season. Plums are plenty, but of poor quality, and mostly the common blue. The green gage is to be found in many gardens; some fine yellow eggs, and Huling's superb, and Bolman's Washington, &c., have been selling at 12½ to 25 cents per quart, while the common sorts would scarcely sell for so much by the bushel; and so with

peaches; fine, large, good flavored peaches command \$2 per bushel, while the great bulk of those brought to market, are sold for 37½ to 75 cents. In fact, persons who have been in the habit of eating fine peaches, would scarcely consider the great bulk of those that come to market at all palatable. Such fruits only encumber the ground, for they will never sell for enough to pay for picking them.

Quinces are well worthy of cultivation, and yet are exceedingly scarce. This region is well adapted to their growth—they bear abundantly wherever they are to be found, and sell readily in market for \$1.50 to \$2.50 per bushel.

The cultivation of the small garden fruits, such as strawberries, raspberries, currants, gooseberries, &c., is much neglected; they are easily procured, easily cultivated, and add greatly to the comforts and luxuries of the family board, at a season of the year when fruit is generally scarce. P. B.

Transplanting.

The fall is decidedly the best season for transplanting all kinds of hardy trees, though this is contrary to the general opinion throughout the country. Many say they have never succeeded as well in the fall as in the spring. The reason of this is that their fall planting has not been performed in due season. If trees are carefully planted and secured from being blown about by the winds, any time in the latter half of the month of October, or the first week in November, they will gain nearly a year's growth over those planted the following spring. Besides the spring is always a busy season with the farmer, and the planting of trees, shrubs, &c., if deferred till then, is too frequently forgotten entirely.

Persons who intend planting orchards or making improvements around their dwellings by planting ornamental forest trees and shrubs, &c., should avail themselves of the very earliest period of the present month suitable for doing so. It is also the only proper time for transporting trees, &c., to the interior of the country. Trees can be carried safely by canal to the most distant west, if shipped early; in spring it is quite impracticable, as vegetation is invariably too far advanced before canal navigation commences.

Many persons possessing a heavy clay soil, have become quite discouraged from their trees dying year after year: several have told me that it is no use for them to plant more, as they will not live. The difficulty is, they have taken no more care in planting than is requisite in the finest sandy loam.

In stiff adhesive soils, the subsoil should be dug out at least one foot deeper and two feet farther in circumference than the roots of the tree require, and good friable surface soil filled in; and the surface should be kept as well hoed as a flower border, during the first year at least after planting. Let those who have a heavy clay soil, pursue this practice and they will be successful. P. B.

Orchard Caterpillars.

Attentive observers will doubtless have noticed that these insects have been on the increase for a year or two past, and it would be well if effectual measures were taken to destroy them while their numbers are yet small. The perfect insect deposits its eggs, during the latter part of summer, in the shape of belts or cylindrical rings on the smaller branches and near their extremities. These rings are then covered with a resinous substance which excludes moisture and they remain uninjured till the following spring, when the young caterpillars hatch, grow, and devour. Each ring of eggs produces a nest of caterpillars.

At this season of the year, these nests of eggs are easily seen, and if cut off and burned, the operation will save the more troublesome task of destroying the insects next spring, and at a season when less time is allowed for its faithful performance. J.

We have received from a respected correspondent in Michigan, several articles on the subject of a Tariff for protection. Our correspondent shows only one side of the question, and that certainly not the most popular. The true wisdom is to hear both sides. We certainly shall admit no articles properly speaking of a partizan character, but this does not preclude the fair discussion of a subject so intimately connected with the agricultural interests of the country as this. Our own opinions on this subject have been very fully and frankly given; but we are not the less willing to hear the opinions of others for having made up our own; nor to changing or amending our opinions, whenever we see reason to change or amend them. It may be said that Congress having adopted the protective policy there can be no farther reason for the discussion. This certainly, in a government where any laws may be altered or amended, does not apply; and the subject being no longer a matter of doubt and struggle, may therefore be examined the more calmly. Our columns will be as open to the arguments on the one side as the other, and we invite discussion so far as we have room, without interfering with favor of more general interest. Our friend having favored us in this way, will, we hope, do more for us in some way more directly practical.—Ed.

For the New Genesee Farmer

PROTECTIVE TARIFF.—No. 1.

MR. EDITOR—Of several subjects on which I wish to express my views through the medium of the "Farmer," the one foremost in my mind at present, is the subject of the "Home League" or Protective Tariff; from the fact, that hardly an Agricultural paper comes to hand but that contains more or less argument in favor of that object.

I propose to examine, in a cursory manner, several of the arguments in favor of Protective Duties; as they occur in my daily intercourse.

If my views are incorrect, some of your valuable correspondents will be able to convince me of my error through the same medium; and if my positions can be refuted by sound logic and experience, no political bias shall deter me from acknowledging my error. I have no other object than my own information and the promotion of the best interests of the farmers of America.

In the first place, I would state, that I am in favor of "Free Trade" in its literal sense, and opposed to a Tariff for Protection, as a general policy. I consider it nothing more nor less than indirect taxation; but I cannot see why we may not as well or better (under present circumstances,) be taxed for the support of Government in that way as any other.

I am therefore in favor of a *Discriminating* Tariff exclusively for revenue, sufficient for the support of our Government, administered upon principles suited to our Republican Institutions.

What I mean by discrimination is, that the duty should be levied in such a way as to collect a revenue and not oppress the laboring classes. I hold it to be unjust to tax the poor man as much as the rich, for the support of government, by way of a duty on necessary articles, of which the poor individual consumes as many or more than the rich one. For that reason, I am decidedly opposed to a uniform ad valorem duty on all imports. I have no objection to any incidental Protection that may be afforded by a Tariff for Revenue founded upon correct principles; but there is a material difference between a Tariff for Revenue and one for Protection "proper." They are directly opposite in effect.

A discriminating "Tariff for Revenue," if judiciously laid, would not wholly prevent foreign competition, or materially enhance the price to the consumer, but would rather have a tendency to keep up an equilibrium of prices, and encourage legitimate commerce, in opposition to prohibition and smuggling.

It is obvious, if an article is prohibited, there can be

no revenue derived and no business left for commerce, except by smuggling. Unless we import something, we cannot expect to export our products to any extent whatever. Whereas the object of a Tariff for the "protection only of American Manufacturers," would be to prohibit importation, and thereby cut off the government Revenue, and materially enhance the price of goods to the consumer.

I support the "Home League" so far as it goes in discouraging, by way of practice and example, the use of all foreign "gaw-gaws" which are useless or injurious to us as a nation; on the same ground that I would support a temperance society, but doubt the expediency of special legislation in favor of either subject.

I am not opposed to the refinements of life, (such as do not enervate the faculties,) nor to the moderate use of luxuries, providing that we limit our expenses to our income, after providing for the common casualties of life. I do not wish luxuries prohibited, but admitted on such terms as will collect the greatest amount of revenue. Their moderate use is far preferable to a miserly, Shylock disposition, as it has a tendency to keep down overgrown wealth, and distribute the means among the many.

All the civilized nations of the earth have latterly turned their attention more to commerce, and the production of the necessities and luxuries of life: In a great measure, the "swords have been beaten into plough shares and the spears into pruning hooks." We are in the commencement of a new era, and Heaven grant it to continue and progress!

If peace should continue and the earth bring forth bountifully, and pestilence not walk abroad, nor anarchy prevail, all the nations of the earth will produce more than the whole world can consume.

What is to be done with the surplus, is a subject to be considered. It was calculated before the great improvements of the day, that active employment of every individual four hours each day, would produce all the necessities of life. The facilities for producing have increased in a short time an hundred fold; by the use of steam, the improvement in labor-saving machinery, and the application of science to agriculture and the arts. If this desirable state of things continue, who can calculate the immense surplus that would accumulate, under the present rate of consumption, in half a century to come? To my mind, low prices are inevitable.

The great strife among civilized nations, at the present time, is for the ascendancy in commerce, and the facilities of production; and lamentable to contemplate, that, with perhaps one solitary exception, the leading motive that impels them onward, is the aggrandizement of the few, and the consequent oppression of the many. But the tendency of *moral reason* is in the ascendant, and it will ultimately prevail over mere force—but before that is fully consummated, all these systems of government founded in oppression must crumble to dust. I sincerely wish the revolution may be bloodless, but come it must—the vengeance of Heaven will not always be "stayed" upon the heads of those nations that work and starve their population to death, under a wicked pretence of "protecting their industry."

I shall endeavor to show by argument, in my next number, that a *Protective Tariff* is decidedly opposed to the best interest of the farmers of America and the nation at large.

I anticipate that some of your readers may consider the discussion of this subject as out of place in an agricultural paper; on the account of its being ultimately connected with party politics.

I consider it a great National Question, (not necessarily a party one,) and one that concerns the farmers as much as or more than any other class of producers, and as such, I shall endeavor to treat it—wholly regardless of party considerations.

Monroe, Mich., 1843.

J. S. DUTTON.

Protective Tariff.—No. 2.

I propose now to examine the argument adduced in support of a Protective Tariff. The friends of the measure maintain that it will be beneficial to the whole community, from a great contrariety of reasoning.

First, it is asserted by some of the advocates of protection that a duty does not increase the price to the consumer, but merely collects the government revenue out of the foreign producer.

Can any man maintain that the corn laws of England operate in that way? Must they not admit that when those laws exclude our products from the English market, at the same time they cut short their own revenue, and also that the said laws are an oppressive burden upon every class of community except the privileged land holders.

I would ask further, why do the American manufacturers manifest so much anxiety on the subject of protection? Why are we told that unless the duty is raised that the majority of all the manufactories will be compelled to stop business for want of sufficient profits to sustain them? And how can the profits be increased on the manufacture of a ton of iron, or a piece of coarse woolen, or a paper of pins, (by a tariff) unless the prices are raised by it? The fact is, and it admits of no cavil, that the prices are raised by duties, and if they were not, manufacturers would derive no benefit whatever from a tariff; it would be all the same to them whether there was a duty or not, and the manufacturers themselves concede the argument and admit the principle, when they "resolve that a duty upon the raw material is a tax upon the manufacturer."

Another reason set forth in support of a protective tariff is, that by protecting the manufacturer you incidentally protect the farmer, or in common parlance it is called, "building up a home market," which to my mind, is a subtle, deceptive *cant phrase*, that has caused more delusion among the producing classes than every other in the tariff calendar. What! the manufacturers of New England consume all the surplus of this "mighty West!" They could not do it if they were fifty times as numerous; but I am admonished that declamation proves nothing, so to the argument of logic, fact and figures, on which I rely to sustain my views.

They admit that although the farmers at first would have to pay a little higher price for all the goods they consume, yet it would enable the manufacturer to make larger profits than they now do, and the result would follow that a portion of those farmers who are now engaged in agriculture would abandon their business for that which was more profitable; consequently, by the operation of the inflexible laws of trade (supply and demand on less competition,) the farmers would obtain an equally enhanced price for their products.

I am not prepared to say the position is wholly groundless and that it is not a true one to a certain extent in most cases; but let us examine the practicability of the argument in this case. By referring to the last census, we find that there are five millions of persons actively employed in the different pursuits, and that 10 per cent, or five hundred thousand of that number, are engaged in trades and manufactures of every description, and that the whole amount of manufactured goods produced in the United States for that year, was estimated to be worth \$395,832,615, and that the aggregate amount of like manufactured goods imported, amounted to \$51,145,711. Now by applying simple proportion we shall find the result. If 500,000 persons, by the use of machinery, produce \$395,832,615, how many persons will it take to produce \$51,145,711, the amount imported that year? Answer, 64,610 men, women and children.

Is it not obvious then, that if the whole number o

persons required to perform that amount of work were to be taken exclusively from the agricultural community, that there would still remain a number sufficient to produce an immense surplus of agricultural products? Every individual may form his own conclusion what number of those persons would be abstracted from among the present number actively engaged in agriculture, if we were to commence and manufacture every article which we now consume. My own judgment is, that it would not lessen the present number of agriculturists sufficient to produce one million of dollars less than we now do. It must be borne in mind, that manufacturing is mostly carried on by the use of machinery, and the employment of females and children, who could not be employed in agriculture generally, under any circumstances whatever: so that in any view of the subject, the conclusion is certain that America must necessarily produce a great surplus of agricultural products; and as long as we have a surplus, we must depend in a great measure upon a foreign market to establish the price; consequently a high tariff would not raise the price of "bread stuffs" here, but would rather have a tendency, in my judgment, to depress prices, as it would deprive foreigners of the ability to purchase our products by excluding their manufactures from our own market.

Every nation that sustains a commerce, must necessarily produce a *surplus* of some kind; and sound policy would dictate that government should encourage the production of such articles as we can produce to the best advantage, as compared with those nations with whom we exchange products; or at least, that government should place no restriction or impediments in the way of raising those products by burdensome taxes in order to encourage or build up some other interest or business which we as a nation cannot prosecute to the same advantage. Now in what consists the great natural advantages of the United States if not in agriculture, emphatically agriculture, and does not every man respond to the sentiment? Is it not the great balance wheel of our republican institutions and government itself? whilst extensive manufacturing, in the nature of things, is incompatible with the equal rights and equal privileges of a Democratic Republican Government. Manufacturing requires concentrated capital, and creates a great distinction between the employer and the employed; and those two things combined, ever have and ever will oppress the many in every land where they existed; and I religiously believe that no nation of people, whose leading business was decidedly manufacturing, ever did or ever can support a Republican form of government.

Entertaining these views, I am decidedly opposed to the agricultural interest being made of secondary importance and subservient to all others. The natural tendency is to drive all men who have mental energy and active business habits into other employments, which is one cause why the farmers, as a class, are considered by many inferior to the merchant or manufacturer.

I am confident that the farmers work harder, live cheaper, and receive less at present for their labor and capital invested, than the merchant or manufacturer, or even less than they will under the tariff, according to the "compromise act," and I think that the farmers require protection more than the manufacturers, and are at least as much entitled to it as they are.

But they tell us that hard work and plain fare is conducive to health and sound morals; that our sleep is sweet and we are not troubled with Bank debts, and the headache after a night's carousal. I have no doubt that they think extravagance in dress is a great sin in a farmer's family, but not so much so in a merchant

or large manufacturer; and what is that but the doctrine of all monarchies and a sure way to build up and perpetuate a privileged order. Now I claim for the farmer, after producing his share of the wealth of this nation, as much leisure time for the cultivation of the intellect, or to be appropriated to pleasure, as any other class of producers; but such is not the case at present; and I call on the advocates of protection to give the farmer "protection" direct—give us a bounty of 20 per cent on all the products which we export, (that would be perfectly consistent with the doctrine and practice of "protection"). The farmers have the same argument to offer that the manufacturers have; namely, that a portion of those persons at present engaged in trade and manufactures would then engage in the more lucrative business of farming; and then by the operation of the same laws of trade, (supply, demand and competition), merchants and manufacturers would obtain a higher price for their goods than they now do.

I have no doubt that supply and the demand, as a general rule, establish the price of all our staples. The doctrine must be considered good in a healthy state of trade; but sometimes the spirit of monopoly, through and by the instrumentality of a *credit system*, subverts all those salutary laws; I offer, therefore, for the consideration of the farmers, another proposition to raise the price of their products,—suppose they spend a portion of their time in ornamenting their grounds with fruit trees and shrubbery: produce less in quantity at a greater per cent profit, by cultivating less land—not forgetting the most important of all culture, the *cultivation of the mind*—and my word for it, they will, as a class, be in better circumstances in a short time than they will be with a "protective tariff," or to continue on in a system of overproduction. To ensure the more we produce the more we enrich the nation at large; (as it certainly will be exported when at very low prices here,) and furnish cheap bread for the mechanic, the merchant and the manufacturer. At the same time when we produce a large surplus, we lessen our own profits, while they in their turn, are not willing to come down to our profits, but are calling on government to protect them by giving us high priced goods and manufactures.

J. S. DUTTON.

Monroe, Mich., August, 1842

Agriculture in Russia.

The estates are estimated by the number of souls upon them, taking into account the *male serfs* only. This is an ancient custom derived from the old times, when the revenues depended upon the number of hands at the disposal of the owner. At present the case is changed; the land is the source of the profits, while the serfs are a dead weight upon the proprietors. The custom of the country is to allot to the peasants the half of the land which belongs to the owner of the estate, to defend them against all aggression, and to respect their property with strictness.

With these means and this order of things, the peasant is by no means in a bad condition. His habits and desires are, owing to his want of civilization, simple in the extreme. But were his wishes enlarged, he could easily gratify them; land, and the time to cultivate it, are at his disposal. A village of 200 souls, (i. e. male peasants of all ages,) possesses usually 2,000 acres of productive land. Two hundred souls are usually reckoned to furnish 80 laborers, women and men; for the wives toil as well as their husbands. These work 3 days in the week for their master, who gives up to them in return, the half of his land.

The system of agriculture is triennial, with fallows: that is, the land bears two crops in three years. Each married couple receives two acres in each of the three portions, i. e. winter grain, spring crop and fallow, into

which, by this system, the arable land is divided so that they have in all 6 acres, in addition to one acre of meadow and one also of pasture: besides this, they have the ground for a house, garden and out-buildings; by way of rent for their allotment, the peasant and his wife are required to cultivate as much more for their master.

The fine season being very short, the operations of husbandry are performed with surprising activity. The vast tracts covered by abundant crops, are quickly barred, and the produce is heaped up in open barns. In winter the grain, consisting of rye, (the staple food of the country) wheat, barley, oats, pease, millet, and buckwheat are threshed, usually with the flail, but sometimes with a Scotch threshing machine, and it is then transported into the towns—sometimes to a distance of 100 or 200 versts, that is 67 or 134 miles. The straw is consumed by the cattle, and is also used in the steppes, where wood is scarce, for heating the stoves. There is, however, often a surplus, which is employed to make fences for gardens, or embankments for ponds and marshes. The roads and highways not being stoned, the immense transports of produce can, generally speaking, only be made in winter on sledges; if it ever takes place in summer, it is effected by means of oxen, the keeping of which costs nothing, since the road itself supplies them with pasture, for it is not less than 210 feet, or 30 sagines wide, and all as green as a meadow. A few ordinary sheep, pigs, poultry of all kinds, and one or two cows in addition to the horse of a very sorry kind, complete the live stock of the peasant, and help to consume the produce of his land, which he cannot sell at any price, however low, on account of the distance of the markets. In a year of plenty, the different kinds of corn become exceedingly cheap, and are consumed with a reckless improvidence, since no one thinks of laying any thing in reserve. And this will explain the terrible deaths which sometimes visit Russia.

Every peasant cultivates for his master and himself, in addition to the fallow, eight acres and mows two acres of meadow. Every acre, in a plentiful year, gives not less than ten measures, termed chetverts, of grain, equal to 216 lbs. An opinion can, therefore, readily be formed of the immense quantity of the produce annually raised in Russia, of which more than one half remains on their hands, owing to the lowness of the price and the prodigality of the consumption. Two or three successive years of good crops overload them to the greatest possible degree; and the storehouses are not capacious enough to contain the corn raised, the more so, as buildings of all kinds, from the scarcity of stone and wood, are expensive.

However full of grain of all kinds the storehouse may be, it is utterly impossible to check the production—they cannot dismiss their laborers (serfs) when they do not want them, as if they were hired laborers. And in spite of the superabundance on hand, they must continue to produce, were it only by way of employment. In fine, the result of this state of things is an extreme lowness in price of all articles, almost below the cost of production. Witness the following prices of produce at Tamboff in November, 1837. Meat from 1 to 4 cents per lb.; Rye, per chetvert, 87 1-2 cents; Potatoes, 15 to 20 cents; Fat Turkeys, per pair, 43 cents; Geese, per pair, 58 cents; Fowls or Ducks, per pair, 30 cents; Flock Game, 24 cents; Gelinottes, 40.

Tomatoes a Cure for scours in Pigs.
Last fall, we had a pig that was taken with the scours badly. We tried various remedies for it with but little effect. One day we threw over to it two or three tomatoes, which it ate readily, and which we found gave it relief. By following this course a few days, it was finally cured.—*Alma Farmer.*

Indian Corn.—The first severe frost of the season occurred in the vicinity of Rochester on the 23d Sept. The largest portion of Indian corn was beyond its injury.

From Colman's Second Report.

Shakers' Establishments.

In a survey of the Agriculture of Berkshire, it would be inexcusable to pass over these establishments.

1. The Family at Tyringham consists ordinarily of one hundred members. The farm is understood to contain more than one thousand acres, principally situated on the side of a high hill, and running down into the valley, where it is crossed by the small stream called Hop brook, which empties into the Housatonic river at South Lee. The view from this eminence, as the prospect extends towards the northwest, embracing the village of Lenox, "set upon a bill," with the whole intervening valley of a diversified aspect and luxuriant soil, the little manufacturing bee-hive of South Lee, and the many rich summits every where scattered in the background of the picture, their tops and sides fringed with the chestnut and the rock maple; and the noble pile of Saddle-Mountain lying in the distant perspective like a contemplative giant in his repose, is among the most beautiful of those enchanting views, which are constantly opening upon the traveller, in this picturesque region.

The principal object of their farming, at Tyringham, is the raising of stock; neat cattle especially. Their dairy is well managed; and they have a garden of four or five acres, devoted to the raising of garden seeds and medicinal herbs, under skilful and successful cultivation. Their annual sales have sometimes amounted to \$3,100; and they allow to their agents twenty-five per cent. commission on sales, and take back what is unsold. They produce some wheat, corn, and oats; and they are now effecting with great labor and admirable skill, the redemption of extensive alluvial meadows on Hopbrook, by draining, rooting out the stumps, and cultivating the soil, which will bring those lands under a course of most productive improvement.

Of the religion of this peculiar people, it is not for me in this place to speak. A religion which holds the severest restraint over appetites and passions ever liable by their excesses to lead men astray, which encourages industry, frugality, mutual love and kindness, and that which is certainly not lowest in the scale of virtues, the most exemplary neatness and order in every thing, is so far entitled to respect and commendation. Under whatever aspect we view it, we have at least occasion to congratulate ourselves, that we live under a government tolerant to every honest difference of worship and opinion; and to remember, that the same principle, which secures freedom to ourselves, should guarantee to others a like boon.

2. The establishment of the brethren at Pittsfield and Hancock, consists of about seven hundred acres, lying together; and is possessed by three large families, containing upwards of three hundred individuals. They are united for all the general purposes of their society; but in their financial concerns are as families separate from each other. The land is not of the best description, being low, cold and wet; and their attention is mainly directed to the cultivation of grass and garden seeds, and the keeping of cows and sheep. Their first purpose is for their own supply. They raise the best they can, and they eat the best they raise; and though from their temperate and careful habits their thrift is remarkable, yet the accumulation of property is evidently not a principal object with them. They have various mechanical contrivances by which their labor is abridged or lightened. They have made the best use of the water power which their place furnishes, and husband it with care and economy. They have an extensive saw-mill carried by water, and all their fuel is cut in the same way. A simple arrangement which it may appear

trifling to mention, impressed me by its shrewdness and good judgment. Ordinarily, fire wood is piled horizontally, and when exposed to the weather, becomes water-sunk and mouldy. Their billets of wood being sawed were stacked up in convenient piles, the sticks being placed upright on the end, so that any water which fell upon the pile was immediately drained off. After being sawed they were neatly put up under cover.

I have already referred to their magnificent barn, built of stone of a circular form, three stories in height, ninety-six feet diameter, and capable, as well as may be calculated, of containing from three to four hundred tons of hay. The carts enter in the second story; the floor or drive-way is continued round by the wall for the whole of the circle, so that the cart passes round the entire distance, and when the hay is discharged, goes out at the same door at which it entered. All the hay is deposited in the centre. Several loaded wagons may stand in the floor, and be sheltered and unloaded at the same time.

The roof is a beautiful and curious specimen of carpentry; and appears to be most securely supported. In the centre of the floor, there rises to the apex of the roof a single column as large as an admiral's mast, around which a hollow frame of slats is fixed, and which serves as a ventilator or chimney to discharge the steam of the hay. It is open at the top, and protected by a small cupola against the rain. At the same time the hay is raised from the ground, about a foot by an open floor of slats, so that there is, while the hay is new, a constant circulation of air up this chimney; and one of the friends informed me, that the steam passing from the hay in this mode was oftentimes so dense, that, to use his own expression, "you could wash your hands in it." The arrangements for the cattle are in the lower story, where every animal has its place and number, and where every cow is designated by a label on the post as in milk or otherwise. In this circular form, there is of course a considerable loss of room; yet the method of feeding is easy; the place is kept clean; the whole arrangement is convenient; and the kindly treated animals standing around this huge mass of hay, have at least the pleasure of seeing the good things in store for them. These friends have singular advantages, in the amount of labor which they are able at any time to command and apply to any object which they have in view; and their establishment presents a beautiful illustration of the advantages of well directed industry, neatness, and order. The great rule of domestic economy "a place for every thing, and every thing in its place," is no where more strikingly exemplified; and though they make no pretensions to the fine arts, and have little of what is called taste, yet all their arrangements, and the products of their labor, exhibit the proofs of tidings, permanency, utility, and substantial comfort.

Their dairy is exquisitely neat in every part of it. Their piggery is the exclusive concern of a single individual; and illustrates the utility in a large concern of a division of labor and of individual responsibility. They have attempted an improvement of their neat stock, by the introduction of some of the improved breeds, and the young stock which they were raising from this cross, promised extremely well, though no opportunity had been had to test their qualities for milk. Their land is considered in a great measure unfavorable to the production of grain; and a large portion of their bread stuff therefore is purchased. They have likewise occasionally hired extensive tracts of meadow on the Mohawk river in the state of New York, which they have cultivated by colonies, in order to obtain brush for the manufacture of brooms, a branch of business which heretofore they have carried on to a con-

siderable extent. They keep a large flock of sheep; and all their woollen fabrics are manufactured among themselves. They likewise are very extensively engaged in the raising of garden seeds, which are put up in a very neat manner, as is well known, and distributed over the country.

A three story brick building or college, erected for one of their families, is most remarkable for its neatness and the excellence of the materials and workmanship. What by the "world's people," is called taste, that is a study of symmetry and beauty in the forms of objects, is studiously abjured by this remarkable community. Yet in the perfection of finish, which they bestow upon every production of their mechanical industry, they show that native perception of fitness, order, and harmony, which constitute the elements of the most cultivated and refined taste. The same amount of expense and labor, of which they are never sparing, already devoted to the construction of their buildings and the arrangement of their grounds, had they indulged themselves even in a slight degree in tasteless ornament and embellishment, without impairing at all the convenience, utility or permanence of their works, might have rendered them extremely beautiful. In so doing they would have found in them a new and prolific source of pleasure, may I not add also of improvement. I know their candor will pardon these suggestions which have no unkind origin; and which have their foundation in the universal beauty of the natural world, as seen every where and always even in the perishable crystals of the frost, and the fading tints of the sky, in the plumage of the birds, in the unrivalled splendor of the vegetable world; in a word in every production of the divine power and goodness from an atom floating in the sunbeam to a planet, wheeling its course in the glittering arches of the skies.

From Colman's Second Report.

Compost and Liquid Manures.

Manures are the very sinews of agriculture; its food; its life-blood. To this matter the attention of most farmers cannot be too strongly directed.

It is generally conceded that all animal manures have most efficacy when applied in the greenest state. They are then most active; and their chemical effects upon the soil are immediate and powerful. In a direct application to the soil, however, they cannot be very thoroughly intermixed; and on this account, without question, they are less efficacious than they would be, if uniformly distributed and thoroughly incorporated with the earth. To effect this object in the best manner, it is desirable to form them in compost heaps, with other substances; mud, scrapings of yards, scrapings of roads, sods or decayed vegetable matters of every description; and even simple loam or mould, or any substance which will act as a retentive absorbent. Thus compounded the liquids of the manure will be retained and the escape of the valuable gaseous effluvia prevented; and by being thoroughly and equally intermixed and diffused, the whole mass becomes a valuable and efficacious manure. The amount of manure in this way is greatly increased; and it is believed, that one part of green animal manure combined in this way with two parts of mould, swamp mud, decomposed peat, and even some portion of clay, will prove quite as serviceable as if the whole mass were animal manure applied in a raw and unmixed state. Some intelligent farmers maintain that the proportion of animal manure or dung requisite to impregnate a large mass in compost is much less than I have allowed. This can be always favorably done in a well constructed barn-yard. The bottom of a barn-yard ought always to be kept well covered with loam or mud, or other matters to absorb the liquids of the yard. But it may often be done to ad-

vantage, where the manure on a field designed to be cultivated is seasonably carried out and mixed with mould obtained from the headlands to form the heap, which being turned over and worked up once or twice, will then be fit for use.

There is another matter, to which I invite the attention of farmers; that is, the saving of liquid manures. In the best districts on the continent of Europe, the liquid parts of manure are considered in every respect equal to the solid. There provision is made for saving and compounding them with the greatest care; in stone and water-proof vaults formed under their cow-houses. In our dairy districts especially, where large herds of cows are kept, a great amount of this manure might be secured by vaults, formed under the stalls with apouts leading into them. With a view to the same object likewise, the cattle instead of lying in the yards at night, should be always tied in stalls. If the barn is properly ventilated, and the stalls littered, they will lay as comfortably and securely as in the yards; and the saving of manure would much more than pay for any extra trouble, which it might be supposed to involve. These are homely subjects, but as important as they are homely. Doubling our manures is quadrupling our crops; and whoever will look with disdain upon a manure-heap, is indifferent to some of the most wonderful and beneficial operations of the divine Providence; and to the most remarkable and instructive lessons of religious philosophy.

THE URINE CISTERN.

From Rodcliff's Flanders.

The urine cistern is constructed to contain any given quantity. The usual capacity of the vault is for 1000 *tonneaux*, (barrels containing about 38 gallons, English,) which quantity for the rape crop, will manure little more than two *bonniers*, or seven English acres. But the cistern under the stables is nearly of double size; from this the exterior cistern is filled; and between both the farmer can fairly count upon manuring in the best manner, six *bonniers* or twenty-one English acres; or perhaps two *bonniers* in addition, of crops which do not require so much manure. The whole of this quantity (exclusive of farm-yard dung, ashes, composts, &c.,) is produced by eight horses and thirty six head of cattle, housed winter and summer in well constructed stables, increased by the adventitious aid of the rape-cake and the *ridanges* from the privies. In a cistern of 1000 *tonneaux*, it is not unusual to dissolve from 2000 to 4000 rape-cakes at 2 lbs. each. Indeed neither industry nor expense is spared for the collection of manure, so upon that depend the produce and fertility of a naturally bad soil. The farmer, who fails to make these exertions, is sure to be left in the back-ground.

The cistern is for the most part formed under the range of stables from each stall of which the urine is conducted to a common grating, through which it descends into the vault. From thence it is taken up by a pump. In the best regulated, there is a partition in the cistern, with a valve to admit the contents of the first space into the second, to be preserved there free from the later acquisition, age adding considerably to its efficacy.

This species of manure is relied on beyond any other, upon all the light soils throughout Flanders; and even upon the strong lands, originally so rich as to preclude the necessity of manure, is now coming into great esteem, being considered applicable to most crops, and to all the varieties of soil.

HARLEY'S EXPERIENCE.

Harley who kept a dairy of a hundred cows, near Glasgow, says "that the advantage of irrigating grass lands with cows' urine, almost exceeds belief. Last

season, some small fields were cut six times, averaging fifteen inches in length at each cutting; and the sward very thick."

EXPERIMENTS OF C. ALEXANDER.

The following extract transferred from the Farmer's Magazine to that spirited and valuable agricultural work, Young's Letters of Agricola, is so important and instructive that I subjoin it:

"This intelligent farmer, Charles Alexander, near Peebles, Scotland, had long been impressed with the great importance of the urine of cattle as a manure; and he set about to discover, by a long and well conducted series of experiments, the best method of collecting and applying it. He began by digging a pit contiguous to the feeding-stall, but distinct altogether from that which was appropriated for the reception of the dung. The dimensions of this pit, according to his own account, were 36 feet square, and 4 feet deep, surrounded on all sides by a wall; and the solid contents were 192 yards. Having selected the nearest spot where he could find loamy earth, and this he always took from the surface of some field under cultivation, he proceeded to fill it; and found that, with three men and two horses, he could easily accomplish 28 cubic yards per day: and the whole expense of transporting the earth did not exceed £41. 16s. When the work was complete, he levelled the surface of the heap, in a line with the mouth of the sewer, which conducted the urine from the interior of the building, on purpose that it might be distributed with regularity, and might saturate the whole from top to bottom. The quantity conveyed to it, he estimates at about 800 gallons; but as this calculation was founded partly on conjecture, for he measured not the liquor, it will be better and more instructive to furnish and proceed on DATA, that are certain and incontrovertible. The urine was supplied by 14 cattle, weighing about 34 stone each, and kept there for five months on fodder and turnips. The contents of the pit produced 288 loads, allowing 2 cubic yards to be taken out in 3 carts; and he spread 40 of these on each acre, so that this urine in five months, and from fourteen cattle, produced a compost sufficient for the fertilization of seven acres of land. He states further, that he had tried this experiment for ten years, and had indiscriminately used in the same field either the rotted cow dung, or the saturated earth; and in all the stages of the crop, he had never been able to discover any perceptible difference. But what is still more wonderful, he found that his compost lasted in its effects as many years as his best putrescent manure; and he therefore boldly avers, that a load of each is of equivalent value.

"Conclusions of vast importance are deducible from this statement: and I cannot resist the feelings of placing them in a strong and advantageous light. They speak a volume of instruction; and if we are willing to learn, they must lead to a very material alteration in the construction of our barns. It appears, then, that in five months, each cow discharges urine which, when absorbed by loam, furnishes manure of the richest quality, and most durable effects, for half an acre of ground. The dung-pit, which contained all the excrementitious matter of the 14 cattle, as well as the litter employed in bedding them, and which was kept separate for the purpose of the experiment, only furnished during the same period 240 loads, and these, at the same rate, could only manure 6 acres. The aggregate value of the urine therefore, when compared with that of the dung, was in the ratio of 7 to 6; so that we are borne out by these premises in this extraordinary inference, that the putrescible liquor which in this province, and under the management of our farmers, is wasted and annihilated as far as regards any useful purpose, is in-

trinsically worth more than the dung, as an efficacious and permanent dressing; and if we take into consideration, that this latter manure is not treated with any skill and judgment, it will not seem surprising, that the culture of white crops has never been carried here to any extent, since we have despised and neglected the only means of eradicating them."

Management of Bees.—No. 2.

MR. COLMAN—I resume the subject of bee management. Few insects or animals furnish more materials for instruction and reflection, than the honey bee. Therefore, why not use our best endeavors in preparing good places for their protection, that the millers and moths may not destroy their works. The blind Huber was the first to give mankind a history of that industrious creature, (the honey bee) which so much conduces to man's comfort and happiness.

In the management of the honey bee, very much is required of the apian to guard against the moths. In order, therefore, to do this, it is highly important that we obtain a good hive for the reception of the bees, and lend our leisure moments in taking care of them. The winter, being so long and cold in this latitude, seems to be a great detriment to the honey bee. In warmer countries it seems nothing to keep bees; it is evident, therefore, that they require warm places in the winter season to have them live and do well the following summer. Some apianists bury their bees in the winter, and some let them be exposed to the inclemency of the weather. Those that have practiced the former way, have very often been the losers. I do not think it is a good plan to bury bees, because there are other ways than to bury them in the ground better adapted to protect them through the winter. Those persons who keep bees, should build a good bee house, and have it open to the south that the sun may shine occasionally upon them. I know of no better way to protect the honey bee from the winter storms.

About twenty-five years ago bees were kept to good success—it was easy to raise them and have an abundance of the sweets of life. But of late years it is almost impossible to raise bees on account of the moths getting possession of the hive. There are but few farmers in this region of country that keep bees. They think the trouble and expense in taking care of them, is a great deal more than the profit. Some farmers have good and others have poor luck in keeping bees. I do not see any thing in the way to hinder the farmer from keeping bees, if he will only employ a few leisure moments in taking care of them. I would advise all who keep bees now at present, and intend to keep them for future years, to abandon the old fashioned hive and obtain the patent hive invented by Mr. Weeks. They are, in my opinion, superior to any other hive now in use in the United States.

I think, by using the above hive, bees can be kept as well now as formerly. Why these hives excel all others is, that we can obtain the sweets of life and not kill the bees. It seems a great cruelty to destroy such industrious insects, which conduce so much to human comfort and happiness. In my next I intend to give a more minute detail of the mode in which bees can be kept with success. W. S. T.

South Venice, N. Y. 1842.

Slaughtering and Packing.

The following terms we saw offered on an advertisement at a tavern in Monroe Co., and dated at Syracuse. We thought they might have some interest with the farmers:

Prices for killing, packing and inspecting, including barrels, \$1.25. The offal reserved to the packer. Tallow rendered from 7 to 8 cents. Hides from 4¢ to 5¢. Freight to New York, from 65 to 80 cents per barrel. For rendering and barreling tallow, \$1.25. Cattle will be kept free of expense, while killing off the drove. Syracuse, Aug. 15, 1842.

Mediterranean Wheat.

Every thing connected with the Wheat Culture is of immediate and the highest importance to the Farmers of Western New York. This induces us to give an insertion in full of the subjoined correspondence. The parcel of wheat has been duly received and will be placed in hands which will do it full justice. We acknowledge ourselves in this and in many instances, personally and publicly indebted to Mr. Ellsworth, for his distinguished and disinterested efforts for the advancement of the agricultural interests of the country.—Ed.

PATENT OFFICE.

July 20th, 1842.

Sir—I have the honor to transmit a parcel of Mediterranean Wheat, respecting which much has lately been published, and the peculiar qualities of which are described in the accompanying letters from Dr. Smith of Philadelphia, and Mr. Powell, seedsman, in the same city.

I am, most respectfully yours,

H. L. ELLSWORTH.

Philadelphia, July 14th, 1842.

Dear Sir—Yours of the 6th instant, came duly to hand, and I should have answered it sooner, had business and other circumstances permitted.

That variety of the Mediterranean Wheat which I have sown for several years past, I consider *proof* against the *Fly* and *almost* *proof* against the *Rust*.

For the former, no rational explanation has thus far been given: but the instances have been so numerous where this and the other kinds of Wheat among us have been sown on adjoining lands in the same field, with cultivation precisely the same—where this has remained untouched by the Fly, producing a heavy crop, and the others almost entirely destroyed, that the most sceptical have no longer any doubts upon the subject.

But, that it should so generally escape the mildew we have endeavored to explain from the fact, that it ripens from ten to twelve days earlier, than any wheat now sown in the Middle or Eastern States (as far as my knowledge extends). But that this is a full and satisfactory explanation I am not entirely prepared to believe; for the causes to which we have generally attributed the production of mildew may exist, when this Wheat is susceptible of being acted upon by them, as well as the other kinds.

These causes we understand to be:

1. That state of the *Plant* when the grain is fully formed but very soft and milky, the whole energies of the plant directed to its perfection, and the esp vessels not distended.

2. That state of the *Atmosphere* which tends still farther to distend the vessels; as heavy dews, and fogs and clouds, which obscure the Sun for several hours after his rising.

3. A sudden outbreaking of the Sun, with such power as to rupture the esp vessels of the plant, thereby giving a nidus for the Seeds of the Parasite to take root.

But be the causes what they may, it is rarely if injured by the *Fly* or *Rust*; nor are these all its advantages over any Wheat among us. For it may be sown from the first of September to the middle of October, and upon soil so thin that the farmer would not think of sowing any other kind of Wheat, and yet produce a fair crop.

I have sown it for two years, after a crop of corn and potatoes had been taken from the ground, and fully believe, that the yield after the potatoes, was upwards of thirty bushels to the acre.

If sown early, one and a half bushels per acre will be enough, but if not sown till in October, at least two bushels should be sown.

Now although the straw is so soft that it will most certainly fall in rich ground, still it ripens well, even should the timothy grow up through it and hide it from view. And although the grain is not so white and mellow, as some other varieties of Wheat, still, that it will produce more superfine flour to the acre for a given number of years than any other Wheat now extant, I feel no hesitation in asserting.

I shall be able to supply any moderate quantity in time for sowing, delivered at any place to be mentioned in Philadelphia.

With sentiments of a regard,

I remain your friend,

MOSES B. SMITH.

HON. H. L. ELLSWORTH,
Commissioner of Patents.

Philadelphia, July 14th, 1842.

H. L. ELLSWORTH, Esq.—

Dear Sir—So far as heard from, the Mediterranean Wheat grows more in favor as it becomes better known. Mr. White, formerly a merchant of our city, stated to me last fall, that he had sowed side by side with two or three others, and that this was the only one escaped Rust, Fly, &c. It is an early Wheat, adapts itself to the generality of soil, but especially to light sand—and as it becomes acclimated assumes more the cast of our Orange Wheat. I find a concurring opinion from many neighborhoods, that the Mediterranean Wheat this season, exceeds by great odds, all other varieties. I can supply a clean good article, as per sample, at \$1.75 per bushel.

Very respectfully,

M. S. POWELL,

23 Market-street.

Silk Machine.

Dr. A. K. Spaulding, of Maumee, Ohio, writes, that he has a Silk Machine far superior to any apparatus to be found elsewhere. That it—

1. Secures the most perfect ventilation to the worm in all its stages.

2. It enables the feeder to change them with great rapidity, even a hundred thousand per hour.

3. It furnishes the most complete winding chambers, exactly suited to the wishes of the worm.

4. The cocoons can be gathered from these chambers 500 per cent faster than from any other known, saving all the fluss perfectly clean.

5. It may be adapted to a room of any size, and may be used in any spare room or parlour without injury.

6. It can be made by any one who can use a hand-saw and hammer, and at an expense little more than that of plain shelves—being the most simple and most economical as well as the best method of fitting up a room, ever yet invented, either in Europe or America.

He adds—

“A letter enclosing one dollar current in New York and Boston, free of expense to the proprietor, shall be answered, and enclose a perfect drawing and description so perfectly plain that it may be understood by any one who can read the description—and twenty five dollars enclosed as above shall entitle the payer or payers to free rights, or the right to the country in which they live. Single rights ten dollars, and a perfect model sent to order.”

We confess we are anxious to know something more of this invention; and when we shall have become better acquainted with its merits, will inform our readers of the same.

Indian Corn.

When David Thomas travelled through Indiana in 1818, he visited a prairie near Vincennes on which a luxuriant crop of Indian corn had grown for more than sixty years in succession, without the aid of any kind of manure. He was then of opinion if I mistake not, that the soil contained a mineral substance which contributed to the inorganic structure of the plant; performing at the same time the office of collecting by chemical attraction the carbon and ammonia of the atmosphere, to nourish the organic development of the plant.

When travelling along the alluvial flats of the Cuyahoga in 1828, I noticed that each stalk in a hill of corn produced one large ear and sometimes two ears; I have every year since tried, by high manuring, to produce the same result in my garden, but without success until the present season. I could always produce stalks as thrifty and large as the river bottom, but the ears did not set or fill to the same extent. I attribute my success this year to the accidental combination of a just proportion of heat and moisture at the time when the pollen was distributed; this happy combination nightly takes place on the river bottoms, and perhaps, also, on the upland prairies near the Wabash at Vincennes, by the aid of the heavy night dews and river fogs almost unknown in this region, at least to the same extent of aqueous profusion, as it exhibits on the bottoms and prairies of the great South West.

But *apropos* of mineral or inorganic manures, it is now well known that wood ashes contains about eleven different incombustible substances in greater or less

quantities, all of which must be sufficiently component in the soil, before the perfect development of vegetable growth, and the full maximum of cereal maturity can be produced in the plant; vegetable manures undoubtedly supply all these substances, but they are not sufficiently concentrated or administered in sufficient quantities, to do any thing more than to produce during its decomposition (which in warm lands hardly reaches beyond two or three crops), the maximum yield.

May we not, therefore, infer that the cause of the perpetual fertility of Vincennes Prairie, is the great abundance of decomposed vegetable matter there found, not in the usual form or deposit of semi-vegetable decomposition to be diminished or exhausted by a few years cropping, but in something like the more condensed and indestructible form of wood ashes? I have often wished that we had in our country more analytical skill and enthusiasm in the cause of agricultural chemistry, in order that the theory of mineral manures might be better understood. The learned and indefatigable Sprengel, supported by the opinion of Liebig, has shown incontestably that plants have inorganic parts which must be fed and grown by the aid of inorganic or incombustible food, that they “must have mineral food as well as vegetable food.” These learned authors have faithfully exploded the old physiological doctrine about the essential nature of vegetable matter, their chemical analysis goes to prove that “all plants have two essential parts, an organic and an inorganic part.”

S. W.

Waterloo, Sept. 8th, 1842.

The Prospect of Prices.—The New Tariff.

Farmers should not be discouraged at the present low prices for their products. If our agricultural staples are low, all other commodities are low or will be low in proportion. Besides when prices are low the export of our surplus productions is then the most active. In 1834 the crops were good in England, yet owing to the extreme low prices of flour in the United States, more was exported from this country in that year, than in any one year since that time! It is probable that the wheat crop in Great Britain will be abundant this season. Still as soon as the price in New York falls much below \$5, an active export of that article will commence even to England, not perhaps to be consumed there, but to be sold in bond, out of which large quantities are taken for exportation to foreign British ports, and colonies in the Mediterranean, and in the East and West Indies.

Since the reduction of duties under the new British Tariff, our export trade to England has very much increased. Our packet ships to London and Liverpool now go out full freighted with our agricultural productions, including naval stores and pot ashes, the duties on which are reduced very materially under the new tariff.

Thus we see that the late fall in the price of our great western staple, Flour, so far from being a calamity to the farmer, has had the effect to clear the market by creating an export demand, which, while it gives activity to the market at home, also pays our foreign debt, or brings back an equivalent in specie, commodities, or credits.

In 1838 our Flour Factors in New York were aided by the Banks to monopolize the flour market and prevent an export at \$8 the barrel, which was offered for shipment to Great Britain; the result was that England got her supply from the continent, and the flour which might have been sold at \$8 the barrel, fell below \$6. In New York, Factors, Millers and Banks were ruined; many farmers were ruined, not directly by the high prices they received for their products, but indirectly by the means for speculation, and extravagant living which these high prices induced.

The protective tariff bill recently passed by Congress, is doubtless looked to by high tariff advocates, as the certain harbinger of a prosperous trade to the nation. I wish I could view all its prohibitory provisions with that eye of faith, which enables the friends of restrictive law to look beyond the simple laws of trade, for that mysterious accumulation of wealth, which is based upon buying and selling to each other, at prices sufficiently high to chest both parties into the belief that they are growing rich.

Waterloo, 1842.

S. W.

For the New Genesee Farmer.

MR. EDITOR—In your paper of the last month, I notice some remarks in relation to drinks and the proper time of drinking. The following article, from the writings of a celebrated Physiologist being in point, I have transcribed for your paper, if you think proper to publish it.

S.

Times of Drinking.

If man were as simple and as true to the laws and instincts of his nature as the lower animals, it would be of comparatively little importance at what time he drank, so that it was always in obedience to the truly instinctive demand of his vital economy. But in civil life, where many causes are co-operating to depress the physiological powers of the human body, and particularly to debilitate the digestive organs, it becomes of much importance that the times of drinking should be properly regulated. In regard to alimentation, we have seen that the best interests of the system require that the food should be perfectly masticated, and mixed with the salivary fluid before it is swallowed. We have seen also, that when the food is received into the gastric cavity in a proper condition, the stomach secretes a solvent fluid, which by the muscular action of the organ, is thoroughly mixed with the food for the purpose of digestion; and that when the food is received in a fluid state, containing considerable aqueous matter, the water is first absorbed and then the gastric secretion and digestion commences; because if the gastric juice were to mix with the water, it would be so much diluted that its solvent power would be wholly destroyed. Hence, if in the midst of a meal, or after a meal is completed, a portion of water or other drink is received into a vigorous stomach, and more particularly if true thirst is felt, the organ suddenly and powerfully contracts upon the food and preases it into the pyloric or small end, and by the contraction of a number of the circular fibres of the muscular coat, which gives the stomach somewhat of the appearance of an hour-glass, the food is held there till the fluid, which is received into the splenic or large end, is absorbed,—which is done as rapidly as possible, and then the circular fibres relax and the regular function of the stomach goes on, with little interruption or embarrassment. But if instead of properly chewing our food, and mixing it with the fluid of the mouth, we continually wash it down with some liquid, or between every two or three mouthfuls of food, take a small portion of drink, the fluid and solid ingesta are so thoroughly mixed together that the process of digestion cannot commence till the meal is completed and all the liquid removed by absorption; and this leaves the alimentary contents of the gastric cavity much more dry and compact than if no drink had been taken; and then we greatly retard and embarrass the function of the stomach, and serve to debilitate, relax and break down that organ. Yet while the stomach continues to be vigorous and active all this may be done without any appreciable symptoms of gastric embarrassment; but never without more or less real detriment to the organ and its function. In that state of gastric debility, however, which is almost universal in civil life, the case is very different; the fluid received into the stomach during the ingestion of food, is very slowly and with great difficulty absorbed; and if the food, with little mastication and insalivation, is continually washed down with some kind of drink, the process of digestion, instead of commencing immediately, as it ought to do, will be delayed for half an hour or an hour, and sometimes even longer, till the relaxed and debilitated absorbents can remove the fluid and bring the food into a consistency proper for the action of the gastric juice; and now the food, instead of being properly mixed with the saliva, and thoroughly saturated with healthy

gastric juice as it came into the stomach, mouthful by mouthful, lies in an oppressive and almost impenetrable mass, and the already weakened organ must, if possible, in its relaxation and lassitude, secrete a sufficient quantity of solvent fluid to digest it. But in this state the stomach is poorly fitted to secrete a healthy and energetic fluid; and, therefore, it is not surprising that under such embarrassments the vital powers of the debilitated and worried organ, are not able to control the inorganic affinities, but suffer them to become active in the formation of gases and acids, which by their acrid and irritating properties, create a morbid and intense thirst, which vehemently asks for some liquid to dilute those acid substances and almost irresistibly compels us to drink. If, however, in this state of things, we yield to the morbid demand, and take a quantity of water or any other liquid into the gastric cavity, the feeble organ cannot, like the vigorous stomach, contract upon its contents, and save them from the inundation; but the flood will come down and sweep over the entire mass, and reduce it to a more unmanageable wash than it was at first; and then will follow a distressing sense of distension, attended frequently with eructations and belching, and often a part of the crude contents of the stomach, are spasmodically thrown up, and a part perhaps ejected into the intestines to produce irritations, flatulency, colic, &c. This is a true description of what every day takes place in civil life, in hundreds of individuals; and if all who indulge in the mischievous practice of washing down their food with liquids of any kind, do not experience all these evil consequences, they may be assured the practice always tends to such results.

If the use of even pure cold water with our food in the manner I have described, is incompatible with the physiological interests of our bodies, and the cause of functional disturbance and organic debility, much more is that water objectionable when it is habitually used hot, for the same purpose and in the same manner. As with our food so with our drink, every thing taken into the mouth and stomach in a higher temperature than our blood, is relaxing and debilitating to the parts on which it acts, and through them to the whole system. The teeth and every other organ and part in the oral cavity, are injured by hot drinks; the throat and oesophagus and stomach are relaxed and debilitated by them. In short, as we have seen, every part of the system is in some measure relaxed and debilitated and rendered more liable to disease, by the dietetic use of any thing in an elevated temperature; and if, instead of hot water or milk and water, we use tea or coffee or chocolate or any other made beverage, the mischievous effects on our digestive organs are still greater, and always in proportion as the qualities of those beverages are more or less unfriendly to the vital powers of our bodies. Tea and coffee and wine and all other narcotic and alcoholic beverages are exceedingly deleterious, but as I shall have occasion to speak of them more particularly in another place, it is not necessary to say more concerning them now.

On the whole then, in regard to the drink of man, it were best, and most truly natural, if his dietetic and other habits were such that the demand of his vital economy for water, were fully answered by the aqueous juices of the fruits and vegetables which properly composed a portion of his food. But if he must have drink, every law and property of his nature unequivocally declares that it should be the most perfectly pure water; and that he should not drink it warmer than his blood; and as a general rule, it is better that it should be considerably cooler. It can be too cold, but with people in health and of good habits, there is very little danger in this direction. It is also,

fully evident that as a general rule, drink should not be taken with the food, nor too soon after eating. It is far better, if one is thirsty, to take a draught of pure cold water some twenty or thirty minutes before eating, or three or four hours after the meal; and they who are regular in their habits can regulate their thirst with perfect ease and comfort. An individual whose dietetic habits are tolerably correct, may soon accustom himself to take a glass of water in the evening or morning, or any other hour in the day he chooses, and only at that hour; and he will feel his thirst return regularly at that period, and never trouble him at any other time, unless occasioned by something extraordinary. They who are tormented by a morbid thirst produced by gastric irritation from too much or from improper food, had far better take active exercise in the open air, than drink. The cool fresh air upon their skin will greatly abate the fever of their stomach, and thus alleviate their thirst; and exercise will increase the action of the stomach and enable it to digest or to reject its contents; and then let them be more careful to avoid transgression.

Statistics of Vegetable and Animal Life.

Botanists record 56,000 species of various plants—35,000 are to be found in catalogues. Humbolt makes the species of insects 44,000, of fishes 2,500, of reptiles 700, of birds 4,000, and of mammiferous animals 5,000.

Important Notice.

There is a large amount due us from Post Masters and Agents in the Western States and elsewhere, mostly in small sums it is true, but our whole resources depend on such small sums, and therefore we hope no one will delay sending on that account.

¶ *One word to our friends.*—We have a large supply of back numbers of the current volume on hand, which ought to be in the hands of subscribers. Will you not help us—would you not be doing your neighbors as well as ourselves a real kindness, by soliciting them to subscribe? The currency is now considerably improved, and bills of most of the states will answer for remittances.

PUBLISHERS.

Cattle Shows, Fairs, and Ploughing Matches.

We subjoin a notice of the times of holding the several Agricultural Fairs, which come within our knowledge, within the district where our paper principally circulates, and shall keep it until the times arrive. We shall be obliged to the Secretaries of the different Agricultural Societies in New York, Ohio, New England and Canada, if they will give us (post paid) the notices of their respective fairs.

Postponement.—On account of the session of the Circuit Court in Canandaigua at the time first appointed for the Show and Fair of the Ontario Agricultural Society, the Show and Fair are postponed by the Executive Committee to Tuesday and Wednesday, the 18th and 19th of October.

Advantages of Law.

A young man who studied law in Connecticut, became acquainted with the following facts, which are certainly very remarkable, though not so singular. A farmer cut down a tree which stood so near the boundary line of his farm, that it was doubtful whether it belonged to him or his neighbor. That neighbor claimed the tree, and presented the man who cut it for damages. The case was continued from court to court. Time was wasted, temper soured, and friendship lost; but the case was gained by the prosecutor. The last my friend knew of the transaction, the man who "got the case" came to the lawyer's office to execute a deed of his whole farm, which he had been obliged to sell to pay cost! Then, houseless and homeless, he could thrust his hand into his empty pocket, and triumphantly exclaim, "I've beat him!"—Selected.

FRUIT TREES,

Of Excellent and Proved Varieties

In addition to the list of Peaches given in the last number of the New Genesee Farmer, the subscribers have for sale the following select varieties of the Cherry: viz.—Black Tartarian, White Tartarian, Early Richmond, Black Crown, Mayduke, Transparent Gage, and Carnation. The trees are of large size, and of uncommonly handsome growth, price 50 cents each.

Nectarines, two excellent varieties, the Early Violet and Elrings, price 25 cents each.

Apricots, three very fine varieties, the Breda, Early Peach, and Peach apricot; 37½ cents each.

Pears, six excellent varieties, Madeline, Skinless, Julienne, Summer Bouchretien (or September), Seckel, and Virgalieu; 37½ cents each.

Apples, consisting chiefly of select summer and autumn table fruit, and a few winter apples, of the following varieties; Yellow Harvest, Woolman's Early, Sea Queen, Non-Buffington's Early, Strawberry, Rambo, Bullflower, Tallman Sweeting, Swann. Price 25 cents each.

The object of the proprietors has been to reduce their list to a few of the very finest kinds, and none are ever offered for sale by them but PROVED VARIETIES whose adaptation to our climate has been fully tested by experience.

Catalogues, with practical directions, furnished gratis at the Rochester Seed Store, or on postpaid applications.

J. J. THOMAS.

W. R. SMITH.

Macedon 10 mo. 1st, 1842.

M. B. BATEMAN respectfully informs his friends and customers, that he has disposed of his business, and all claims of debt are soon for the benefit of his health; he therefore earnestly solicits all who are indebted to him to make immediate payment, in order that he may be enabled to go to his home in the West. The business of the Rochester Seed Store will be continued by C. F. Crossman, whose experience in the business and facilities for growing Seed, entitles him to the confidence and patronage of the public.

M. B. BATEMAN.

Oct 1.

ROCHESTER SEED STORE AND SEED GARDEN.

NEW ARRANGEMENT—C. F. Crossman having purchased the entire business and effects of the Rochester Seed Store, desires to inform the Agents and Customers, and all who may wish to patronize the establishment, that he is now bringing in from his large Seed Garden in "Marquette," a complete assortment of such seeds as are best raised in this climate, and he will import from the first seedsmen in Europe and elsewhere, such kinds as are better raised in other climates. And such of continental vitality will be thoroughly tested by sowing, and none offered for sale but such as can be warranted genuine. The proprietor is fully confident that his long experience in the business of growing and vending seeds, will enable him, with strict attention to conduct the business in a manner that will prove satisfactory to the public.

Rochester, Oct. 1.

C. F. CROSSMAN.

SALE OF DURHAM SHORT HORNS IN CANADA.

THE Subscribers propose to sell by public sale, in Dundas (Plainboro') West, on Saturday, Oct. 13, being the day of the Gore District Agricultural Show, a valuable herd of thoroughbred DURHAM BULLS. The animals are half-bred, and of fine symmetry, and correct Herd Book Pedigrees will be furnished. Their ages vary from fourteen months to four years and. Hereafter, be reminded that this is our opportunity of obtaining Genuine stock.

To us fair and liberal, Easy water conveyance from Dundas is. Sale to commence at 12 o'clock noon.

Orders to Mr. H. WITTE.

ADAM FERGUSON.

Same day and place Mr. H. WITTE will expose a large and valuable lot of RAM LAMBS, pure Leicesters, South Down and Cross. Also, six valuable calves, one year old.

MOUNT HOPE GARDEN & NURSERIES.

ROCHESTER, NEW-YORK.

THE Proprietors of this Establishment offer for sale a general assortment of Nursery articles, comprising Fruit and Ornamental Trees, Flowering Shrubs, Herbaceous Plants, Tulips, Hyacinths, and other Bulbous Flower Roots, Double Dahlias, &c. &c.

They have also on hand a large and fine collection of Green and Hot House Plants, including Geraniums, Chinese Monthly Roses, Camellias, Japonicas, Chinese Azaleas, &c. &c. &c.

Orders for any of the above articles, whether large or small, will be promptly and faithfully executed, and charges in all cases will be very moderate. Persons ordering from this establishment may rely on their articles being carefully packed and marked and shipped as their orders may designate.

To such persons as are about forming new establishments or who may wish to dispose of Trees, Shrubs, Plants, &c. in their neighborhood, our terms will be very liberal.

Gardens and Pleasure grounds will be laid out in any part of the country, and skillful gardeners furnished on reasonable notice, and information, and all subjects connected with the business will be cheerful and promptly imparted.

It is expected that persons unacquainted with the proprietors will either accompany their orders with a remittance or name a guarantee in the city of Rochester or vicinity.

ELLISWAGER & BARRY.

Rochester, Oct. 1, 1842.

Our Fruit Trees comprise the most desirable early and late varieties, and the utmost care has been taken in propagating from such trees only as were in a bearing state and whose qualities have been sufficiently tested. Price Catalogues will be forwarded gratis to all applicants.

COTSWOLD SHEEP.

AND OTHER FINE STOCK, FOR SALE.

THE Subscribers offer for sale, his full blooded Cotswold Bred, Blackmore, imported or bred by Thomas Dunn of A. Bayly. Also, thirty 3-4 and 7-8 Cotswold Bucks, Yearlings and Lambs. Also, his thoroughbred Durham Bull Animal, bred by or for his friend, Durham Heifers. Also, a thoroughbred Leicester Bore.

These animals will be sold on the most favorable terms—at prices according to the times. It is not previously disposed of, but he is charged with the duty of being sold at the Show and Fair at Rochester on Tuesday, the 23rd of October.

W. M. C. COINELL.

Henrietta, Sept. 21, 1842.

10,000 PEACH TREES.

FOR sale by the subscribers at their Nursery, (near Macedonville on the Erie Canal), all of which have been propagated from BEAUFORT TREES, whose genuineness or excellence has been thoroughly proved. They are of fine and very thrifty growth, and have all been at least once transplanted, and the danger of loss or even check in growth from this operation, is exceedingly lessened. Price 25 cents each, 2500 hundred, \$1500 per thousand or \$1500, well packed and delivered.

The following are the chief varieties, which will afford a constant succession of ripe fruit from early in May (Aug.) till late frosts, ripening according to the order in the list.

1. Early Yellow—fruit medium size, excellent, a good bearer, and a most valuable early peach.

2. Large Yellow—fruit large, excellent. Ripens ten days later than the preceding.

3. Early York—large sweet and rich; a fruit of the highest character.

4. Early Red—large, white with a red cheek, sweet, juicy and melting, a most excellent peach, abundant probably from the celebrated Noblesse, which it exceeds.

5. Yellow Almond—fruit rather large, one of the finest yellow peaches, and one of the earliest.

6. Seedling's—fruit large, red, of first rate excellence.

7. Red Cheek Malacodon—fruit rather large, beautiful of fine flavor; ranks as first rate among yellow peaches—leaves well white young.

8. Hull's—fruit a very large, fine, yellow peach.

9. Late York—an excellent freestone peach, except in unfavorable seasons.

10. Heath Yellow—fruit when not grown early, and in favorable seasons very large, often three inches in diameter, sweet and excellent.

Orders directed to Thomas & Smith, Macedon, Wayne Co., N. Y., will be promptly and faithfully attended to, and the trees, suitably packed, sent by the Erie Canal, or by the Auburn and Rochester Rail Road.

J. J. THOMAS.

Macedon 9th mo. 1, 1842.

W. R. SMITH.

PLOUGHS.

A NEW AND SUPERIOR KIND OF PLOUGHS, (two sizes) designed for breaking up square and oblong fields, may be purchased at the Rochester Eagle Furnace, price \$60 and \$75 each. Wood and other produce taken in exchange.

A. J. LANGWORTHY.

BUFFALO NURSERY.

THE stock now on hand for sale is much larger than at any former period, embracing a large collection of the most valuable kinds of Apple Trees, viz.—Piedmont, Quince, Nectarine Apple, Filbert, Strawberry, Raspberries, Gooseberries, Currants, &c.

Of Ornamental Trees, Flowering Shrubs and Plants, a fine assortment, comprising almost every desirable article in this department. A large stock of Green-house Plants.

I also offer for sale 25,000 Apple Trees of one year's growth, of the most desirable varieties, in quantities not elsewhere over one foot high. They consist of 130 of the most valuable kinds—four-fifths of which have been from bearing trees and consequently will soon produce fruit. They will be sold at such a low price as \$2. per hundred—No less than from 5 to 10 of any one kind to be taken.

Also, 5,000 seedling trees of the true English Mazzard Cherry, at \$6 per 100.

Orders by mail or otherwise, will receive prompt attention. Trees or Plants packed in superior order and shipped at Buffalo on board of any steamboat, vessel, or canal boat required. Catalogues gratis to every applicant.

Buffalo, Aug. 2, 1842.

B. HODGE.

ISABELLA GRAPE VINES.

OF proper age for forming vines, propagated from and containing all the good qualities which the most improved cultivation for over ten years has conferred on the vineyards at Croton Point, are now offered to the public. Those who may purchase will receive such instructions as will enable them to cultivate the Grape with entire success, (provided their locality is not too far North.) All communications, post paid, addressed to T. UNDERHILL, No. 2, Broadway, N. Y., will receive attention. He feels quite confident that he has so far ameliorated the character and habits of the grape vines in his vineyards and nurseries, by improved cultivation, pruning, &c., that they will generally ripen well and produce good fruit when planted in most of the Northern, all the Western, Middle and Southern States.

PROSPECTUS.
 The subscriber announced himself in the last number of the New Genesee Farmer as the sole proprietor and editor of this paper, after the first of January ensuing. He renews this announcement; and asks the aid of his friends and the agricultural community in sustaining the paper as far as they can conscientiously render that aid; and he will respectfully and gratefully acknowledge every such service.

The paper will be so much enlarged; and if suitable encouragement is given, in all respects essentially improved. He has made arrangements to enlarge his correspondence extensively at home and abroad; and pledges himself that no pains shall be spared to render the paper worthy of support in its matter and execution. He can promise no more than this.

The price of the paper will be one dollar in advance by the year. Six copies will be sent for every five dollars; ten copies for eight dollars, and fifty copies for thirty-seven and a half dollars, paid in good current money. Gentlemen who have heretofore acted as agents are requested to continue their agency. Postmasters are universally found courteous enough to transmit names and subscription money free of expense. Other arrangements as soon as completed and the names of special agents will be enounced in the December number. It is earnestly requested that returns should be made early, that the number of copies to be printed may be ascertained.... The universal complaint is that the times are hard; but the productions of the press, even in times infinitely harder than the present, were never half so cheap as now. The farmer now gets his political paper and two or three agricultural papers for less than what one respectable political paper or general magazine used to cost. The times must indeed be hard, when the farmer cannot afford the miserable pittance, which he may save in innumerable ways, required to obtain that information, which may increase his products a hundred fold; to say nothing of the satisfaction and improvement to himself and family from knowing what others are about, and witnessing the general progress of knowledge and the arts. What the temperate farmer now saves year after year in the expense of spirituous liquor only for his haying, to say nothing of other expenses and losses connected with its use, to which he was formerly subjected, will pay five times over for his agricultural paper, and leave enough to buy eight or ten useful volumes besides for the winter reading of his wife and daughters. When we go into our farmers' houses and see their loaded tables and their comfortable and luxurious clothing and fur-

niture, and hear them talk of hard times, we are constrained to ask ourselves, whether this is the English language which is spoken, for under what sky, in what country, and at what period, were men ever in a condition of more substantial comfort and independence. If they are but just to themselves and to their advantages, no change of times or of prices can seriously effect their prosperity.

In truth we see but one single circumstance, that should hinder every farmer in the country from subscribing at once for the Genesee Farmer; and that is Millers' doctrine that the world is to come to an end next summer. But even Millers' disciples are very anxious to get subscribers at a dollar per head for the "Second Advent Journal" which is now published periodically in Boston, tho' we are quite at a loss to know what they are to do with the money, unless as the Romans believed, there is some ferrige to pay for themselves and other friends before they can get into the Elysian fields. But besides we have been informed by one of their Chief Priests that it is not settled that the prediction is certainly to be fulfilled in April, but probably some time in the course of the next year; so that the farmers will stand a fair chance of getting for their dollar six or eight months good agricultural reading at any rate, besides the satisfaction and merit of contributing to the good cause of agriculture and of helping a poor Editor, who has borne the heat and toil of more than forty years in their service.

Farmers! then we expect you to honor the noblest of all arts, by which you live; and to give us a fair and public-spirited support; and we promise to do our best to deserve it. "Do not muzzle the ox that treadeth out the corn." Do not be too impatient to get a crown in one hand before you let a dollar go out of the other. The welfare, character, and happiness of millions yet unborn may depend on the efforts we now make; and your co-operation that those efforts may be successful. Let us early and late sow the precious seeds of knowledge, wisdom, and virtue and "the Lord of the Harvest will give the increase."

HENRY COLMAN.

Rochester, 1st Nov., 1842.
 N. B. Mr. M. B. Bateham proposes to pass the winter in Ohio and the South Western States, and will act as Agent for this paper—we anticipate likewise the advantage and pleasure of his regular correspondence for the paper.

Mr. C. F. Croaman, of Rochester, is an authorized Agent for this paper. Mr. C. having taken the Seed Store in the Arcade, recently occupied by Mr. Bateham, designs to render the Establishment complete in all its departments. His skill in raising and managing seeds is well known, and his honor and integrity undoubted.

NOTICE.

The Address delivered before the Monroe County Agricultural Society, by H. Colman, together with the Constitution and list of officers and members of the Society, and the reports of the awarding committees, will be published in pamphlet form, for distribution, as soon as they can be prepared.

By order of the Executive Committee.
 M. B. B.

Rain Gauge for Sept., 1842, 5.19 inch.
 " " " " 1841, 6.14 "
 " " " " 1840, 2.81 "
 Mean Temperature of " 1842, 58.04 deg.
 " " " " 1841, 26.96 "
 " " " " 1840, 57.44 "

Remarks on the Weather from September 26th to October 25th.

Sept. 28th, rained a little at night; fair to the end of the month.

October, from Oct. eighth; the eighth month of the primitive Roman year. The tenth month of the year in our calendar.

This month has been mild and pleasant. Mean temperature first half 51.13 degrees. Severe frost on the morning of the 6th.

Oct. 15th, cloudy with little rain; not much wind; but there was a severe gale on Lake Ontario, thro' the day and evening. It has been remarked by those who know, that the Lakes have been "uncommonly rough" this season.

It is remarked by observers, that there are many strong indications of a severe winter.

There arrived at Buffalo on the 10th ult., seven steamers, 5 brigs, 15 schooners, and 1 sloop. These brought a large quantity of produce, among which are 12,471 barrels of flour, and 51,866 bushels of wheat.

SCIENTIFIC AGRICULTURE.

Extracts from an Address

Before the Massachusetts Horticultural Society, at
their Fourteenth Anniversary, by
J. E. TISCHMAYER.

This Address is in all respect so beautiful and admirable, that we know we shall do a kindness to lay it before our readers:

I congratulate you that we again meet to give countenance and support to a pursuit which, at the present day, interests and is the delight of the whole civilized world. Yes, wherever a ray of civilization sheds its lustre on this earth, one of the objects of that ray is Horticulture; it forms the charm of the leisure hour of the highest, the wisest, the best; it is the healthy occupation of the humble, and the industrious.

Absorbed in the cultivation of his favorite flowers, his patch of vegetables, or his orchard of fruits, the poor man carries not the wealth, nor is his sane and well-braced mind disturbed by the disease and empty dreams of the ambitious.

So thoroughly convinced am I that indulgence in these pursuits carries in its train content and cheerfulness, these serene signs of health, both of body and mind, and induces that position of the heart which enables one to view, without envy, without desire, the place of the prince or the luxuries of the nobility, wherever it shall please a kind Providence to allot me a station, there will I to my latest day advocate the cause, encourage the dissemination, and strive for the improvement of Horticulture, with all the powers entrusted to my charge.

How happy for millions had Horticulture, with its refinements, been in earlier times more universally disseminated amongst mankind! What would have been the pages of the history of South America from its discovery to this day, had Pizarro, and the ministers of religion who accompanied him, associated the cross which they bore in one hand, with the spear, the rake, and the pruning knife, instead of the lance, the sword, and the gun, in the other? How different would have been the existence and fate of the whole generations of natives, who passed lives of misery, and were finally exterminated—how different would be, at this day, the face of the immeasurable plains, the far stretched forests, in such a heavenly climate! Her history would have been one of peace and prosperity, instead of one of blood and desolation; her plains would have been covered and adorned with swarms of happy and industrious races, by whom the names and the memory of these discoverers and civilizers would have been venerated & held sacred, like that of Mango Capac, who in ancient times introduced the simplest arts of peace among them, instead of being held in that extermination which has at length resulted in their total expulsion from thence from the country.

Horticulture may be emphatically named as one of the arts which exhibit most prominently the peace and prosperity of a nation, and should certainly be upheld by all to whom these happy results of human reason and divine religion are dear.

I have read in an English agricultural periodical, otherwise of some eminence, several arguments urged rather vehemently against Horticulture and Floriculture. The arguments are chiefly based on the ill-will, the evil disposition, or trickery, which sometimes exists amongst the competitors or judges. As if this evil could be entirely avoided in emulation or competition for any thing on earth, whether for a diadem or for a throne; as if the ill-will engendered by these exhibitions among the few, could be at all placed in comparison with the pleasure they impart to the many, or with the encouragement they afford to a healthy and delightful occupation. The solidity of such objections stands about in the same rank as those to reading and writing, on account of the forgeries now and then committed.

There is, however, much higher ground at the present day, for congratulation to the lovers of the cause whose advance we here signalize.

It is the rank to which Horticulture has recently attained as a science. It is no longer a mere curiosity of gardeners' secrets for propagating or growing certain plants, of nostrums and recipes for destroying insects and cleansing trees; it has become the constantly improving art of applying scientific, rational and well-digested principles, to perfect the cultivation of the vegetable kingdom; it has suddenly almost become a subject of delightful and interesting investigation for scientific men of the most refined attainments.

I am far, however, from despising these secrets, these nostrums; they have frequently resulted from

the close observation of men of most excellent judgment, men who will be the first to accept the aid of science to strengthen their reasoning powers and guide their judgment. I only rejoice that neither the facts themselves, nor the principles on which they are founded, will any longer remain secret; they will henceforward be made known and communicated to all those accustomed to study and to trace exactly the minute operations of nature, to reason and reflect on each new appearance, and to exert all their acuteness in tracing its cause to the utmost verge of human knowledge. And these clear and simple principles, on which all improvements are grounded, must henceforward be described in such plain and intelligible language as will guide those who, without these habits of study and observation, pursue the cultivation of the soil either as an occupation or a pleasure. Horticulture is now capable of becoming to the agriculturist what the chemical laboratory is to the dyer and the manufacturer. It is in the garden and the greenhouse that useful experiments may be made on the value of different manures when mixed with different soils, their effects accurately tested on various kinds of plants, the mode of application carefully and accurately observed, and the economy of that application practically ascertained. And these experiments are more necessary at the present day, when we are inundated with artificial and natural manures and composts of all descriptions, whose virtues and efficacy are boasted of and lauded for the purpose of sale, with more than a pedlar's energy.

Owing to the kindness of Mr. Benjamin Bangs, of this city, who presented to me a small portion of Guano, brought by one of his vessels, the Henry Lee, from the coast of Peru, it has fallen to my lot to try the effects of this much celebrated manure on several plants. The chemical constitution of this substance renders it probable that it is the excrement of birds, which has, during countless ages, accumulated on the Peruvian coast, where it forms beds of considerable thickness, and where it has for several centuries been used by the inhabitants of that sterile coast to raise luxuriant crops of corn. There are this year sixty English vessels employed in fetching this manure to the English markets.

The most recent, and probably most correct analysis of Guano, that by Voeckler, shows that it contains many of the ingredients favorable to vegetation, such as several salts of ammoniac, phosphates of lime or the chief component part of bones in abundance, potash, soda, and as much as one-third of organic matter, which would furnish humus with a little clay and sand.

Immediately on receiving this Guano, about the 17th June of this year, I commenced my experiments, which I will now explain in order, and as briefly as possible.

First observing that all those plants which were treated with Guano were potted in a mixture, consisting of plain earth without any manure, sand, and little leaf mould and peat, with which the Guano was mixed—that those plants which compare with them have been grown in our richest compost—and that both have had the same attention, and been grown otherwise under the same circumstances,

Fuchsia—*fulgens*—one year seedling, potted 17th June, 24 inches high with one teaspoonful not potted up, of Guano—repeated 17th August, then 12 inches high, with another spoonful of Guano—a now 44 inches high.

Plant contrast between this and the two years old plant is very striking, both as to luxuriance of growth and color of the foliage, the plant with Guano being vastly superior. I think also that the color of the flower is improved; it is well known among gardeners that it is rather difficult to grow this plant well.

Parlagonum—two seedlings grown with Guano and one of the same sowing without; on the 17th June these two were potted with one teaspoonful of Guano, and repeated on the 17th August with another teaspoonful; here also the difference in favor of Guano is very great.

China Rose—two cuttings with Guano, potted 17th June, with one teaspoonful Guano—one was then 7 inches high, the other 43; they are now 34 in. & 38 in. respectively, with large healthy foliage and stems; these have not received a second application of Guano.

Celastrus cristata or Cockcomb—one seedling, with one teaspoonful and one of the same sowing without—the size of the stem, foliage, and head of that with Guano is more than double that of the other, and the difference in the green color of the leaves remarkable.

Sylvia patens with one teaspoonful of Guano—the

effect here has been to lengthen the joints, and the flower appears a trifle smaller than usual.

Aceria Farnesiana—a seedling showing the effect of the foliage and length of the joints previous to the application of a teaspoonful of Guano, and the remarkable growth of both afterwards.

Camelia with two teaspoonful 17th June, and no more. This specimen, which was quite small and unhealthy before the addition of Guano, is now as healthy by the lower leaves, exhibits in a most marked manner, by its beautiful large deep green leaves a healthy bud, the action of this manure.

I have also exhibited a Camelia grown with large proportion of wood which, the foliage at least is extremely fine and luxuriant, and of a very healthy green color, but as may be seen, not at all equal to that worked with Guano.

One Balsam, 17th June, 24 spoonful, repeated 9 August with two more to which a little lime was added.

This is an ugly specimen, being nearly past flowering; but I sent it to confirm an observation in the London Gardener's Chronicle, which states that if Balsams worked there with Guano, come with smaller flowers—it is evidently the case here, but I have watched it carefully and found that not a single flower bud forming its seed vessel, and that every seed vessel I have opened, is quite full of perfect seeds containing from 11 to 20 in. I wish this point to be carefully remembered, as I shall sound some farther remarks upon it.

From what I have seen of Guano it is quite clear that its action is rapid and powerful on the stem and foliage, increasing their size and deepening their green color; of this fact there can be no doubt. I think it probable that it diminishes the size of the flower in some cases, and that it improves the seed, both in quantity and quality—of this, however, much more experiment is required to prove the certainty. I have one more remark to make, when these plants were repeated, which received a second application, it roots were very numerous, and appeared in the most vigorous healthy—thick, succulent, pure white, tips with that hairy appearance so well known by cultivators as a sign of strong growth.

In Peru it is customary, when using Guano to raise pepper, to manure three times, first on appearance of the roots, then on the appearance of the leaves and lastly on the formation of the fruit.

I think the experiment of its action on all fruits particularly the larger fruit trees, as apples, pear, peaches, &c., will be extremely interesting, as we as on the vine, which is well known to be excessively greedy for rich soil, particularly for bone manure, the chief ingredient of which, phosphate of lime, Guano contains in considerable quantity.

But if Horticulture be indebted to science for man improvements, it is amply able to repay the debt with interest. The Garden, with its convenient Greenhouse, is the true study-chamber of the Botanist—here he will find arranged, as on shelves, in perfect order for reference and examination, nature's works in thousands of volumes, written in living characters. Here he can consult with, or investigate from, the living plant, the characters and descriptions of the old Botanist, often only imperfectly obtained by their from the dried specimen of the Herbarium; nay here imagination may sometimes even transport him to the once visited Alpine rock, or Tropic forest, and for the purpose of studying properly the plant or his own country, a living collection is highly important. It is impossible for him to exhaust his time in watching the growth, inflorescence or habits of each in its native spot, but collected in the garden or greenhouse, with proper attention to their natural soil and circumstances, this often becomes both practicable and delightful.

For if the Horticulture of the olden time be no that of the present, neither is the Botany of the past that of the present one. The time has gone by when a Botanist could boast, without a blush, that he had never cultivated a plant; he must now know no merely the name, but the nature, of the individual of the vegetable kingdom; he must study their structure during the advance from germination to maturity must become acquainted with the functions of their various parts, must watch their growth and transformations, and examine with his own eye many operations of the living plant, on which it is impossible to gather knowledge from the Herbarium; in fine, the study of vegetable physiology in the living individual, is now indispensable to the Botanist.

It is the want of good collections of living plants that we find here the great barrier to our advance in this science; in Europe, Botanic gardens abound everywhere, into which all newly discovered plant

quickly introduced; and thus the multiplication of the essential means of study is rapid—here we must depend chiefly on books, and I need hardly state how much more valuable and interesting is the book of nature than the book of man. A remnant of the ignorance of the older botanists, I think is found in the opinion of many of them still entertained towards the transformations in flowers, effected by the art of the horticulturalist, either by hybridisation or by the multiplication of parts, causing what is called double flowers. To me this aversion appears to arise from a contracted view of the subject—all these transformations or operations of nature, which all take place in accordance with her laws, and therefore all are deserving of study and of systematic arrangement, and when well understood they must throw much light on the functions of different parts, as well as on the relations these parts bear to each other. Every deviation from regular structure, called by the man of science abnormal, must afford insight into the laws of that structure, and I am convinced that the more these changes are studied by the scientific Botanist, the more enlightened will become the views on those portions of the vegetable kingdom which are now comparatively obscure.

I cannot resist the temptation to explain a single instance where the close observation of the growth of plants is of importance, and I do so most willingly, as the result is likely to be useful, and bears directly on the interesting subject of Guano.

The nectariferous juices, or, as it is commonly called, the honey in flowers, is usually separated or secreted by glandular bodies called nectaries, and this honey has by many been supposed to be of indispensable service in the fecundation of the seed; but there are also glands on the leaves and leaf stalks (petioles) of many plants, which perform the same office of secreting honey; here, of course, it cannot be of use or of this purpose. Such glands exist on the petioles, or leaf stalks, of most of the *Acacia* tribe, on the tips of three or four of the lower serratures on the leaves of *Grewia*, on various parts of the leaves or stems of the *Balsam*, on *Pasiflora*, and many other plants.—The glands only secrete honey during the youth and growth of the leaf; it is then only that their operation and beautiful structure can be properly observed; when the leaf has attained its full growth and perfection, the nectariferous parts close up, and the time for observing their powers is past, and the leaf then proceeds in its own important function of elaborating the sap. It has been lately surmised, and it appears to me with every probability of truth, that this honey is an excretion thrown off, of the superabundant and useless part of the juices, after the leaf or flower has selected all that is necessary, precisely analogous to the excretions of the animal frame. I will attempt, very briefly, to show that this view, if correct, is of some importance both to Agriculture and Horticulture. Mr. A. A. Hayes, of Roxbury, in a beautiful, simple, and I believe original experiment, exhibited before the Chemical Society of Boston this spring, proving the existence of phosphoric acid (probably combined) in several seeds, by immersing sections of them in weak solutions of sulphate or acetate of copper; in whatever of the seed phosphoric acid existed, on that part was deposited a precipitate of phosphate of copper; this was particularly evident in the seeds of Indian corn.

A certain quantity of phosphoric acid, or phosphorus, is therefore necessary to the existence of these seeds, and that part of the plant, (probably the flower), destined to perform the function of preparing the juices for these seeds, must go on exerting its utmost powers in selecting and rejecting until the requisite quantity of phosphates and other ingredients for the seed are obtained. Now the phosphates in most soils exist in extremely minute quantities; therefore, those plants and flowers whose seeds require any quantity, must extract large portions of food from the soil before they can select the amount of phosphates necessary for the perfection of their seeds; and probably only as many seeds arrive at maturity, as the plant can procure phosphates to complete; the remainder, embryos of which are always formed in abundance, are abortive; that is, never come to perfection.

The same line of reasoning of course applies to the other necessary ingredients of seeds. If, therefore, we present to a plant food containing an abundant supply of these ingredients, it seems reasonable to suppose that we shall produce more seeds, or rather that more of the embryo seeds will be perfected. Now I have before stated that the chemical analysis of Guano shows that it contains, in abundance, most of the necessary ingredients of plants and seeds, the nitro-

gen of its ammonia being absolutely requisite for the cellular, vascular and other parts of the stem and leaves, and its phosphoric acid, as well as its nitrogen, for the seeds; and of future experience should confirm what I have to-day stated as an opinion, that the flowers of plants manured with Guano become smaller, it may be accounted for on the assumption that as there is presented to the plant these ingredients in abundance, particularly those necessary for the seed, the flower and its glands, whose office it is to prepare the latter, have less work to perform, less food to analyze, less to select and less to reject; hence there is no necessity to have them of so large a size as where much exertion of these functions is required. The seed will also be larger and in greater quantity.

I offer this train of reasoning on an abstract and little understood subject with the utmost diffidence, and certainly under the impression that we have not yet sufficient evidence or experience on this most interesting manner to offer a solid and well-grounded opinion; but it is at all events a sufficient foundation on which to lay the superstructure of experiment.

Horticulture is probably still in its infancy in this country; but if so, it is the infancy of a giant. How few have hitherto devoted their whole attention to raising new varieties of fruits, flowers or vegetables from seed, and yet we have already, among flowers, the almost unsurpassed *Canella Walderi*, raised by our indefatigable President, with several others of great beauty. The seedling *Pelargonium*, exhibited this spring in the rooms of this Society, are not far from some of the best imported from Europe. In fruits, we may with pride refer to the strawberry, raised by an active member of this Society, which has deservedly acquired so much celebrity.—So many of our native apples and pears, to Mr. Manning's cherries, to several new plums which have been exhibited. I have also tested seedling peaches from private gardens, unnamed and little known, which may successfully vie, for flavor and size, with many European fruits possessed of high sounding titles. And indeed, we have everything to encourage endeavors in this branch—for it requires but little attention from the hand of man to produce these improvements.—Nature has been lavish in her gifts to this climate.

The glorious beauties of our sunsets amply attest the purity of our atmosphere, and the almost tropical sun which rides over our heads during the summer months, perfectly matures the wood, the juices, the pollen and the seeds of our plants. For the grateful shade of other lands, the ingenuity of the Horticulturist here can easily find a substitute, beyond to produce or imitate our glorious sunlight, is beyond the art of those of many other countries. It has been thought that our long winters are a serious impediment to our Horticulture, but it is not so. The very essence of this pursuit is to overcome difficulties, to make the wintry desert blossom like the rose; if every circumstance were favorable, if everything flourished spontaneously, of what value would be the exertions of the gardener? It is the long privation of the charms of Flora and Pomona, by our protracted winter, which makes them so eagerly sought after when they do come. The very length of our winter acts, on the one hand, as a stimulus to the gardener to produce his early fruits and flowers; and on the other hand, increases the desire of the patrons of Horticulture to enjoy them. I believe that it would be a very profitable speculation for the builders of new houses in the country, or even in the town, to contrive, at the back of each, a small greenhouse about 15 by 12, just enough for the inhabitant to employ his leisure hours in cultivating, with his own hand, a few exotic plants. The expense of this structure could not exceed \$400, or \$150, and no doubt many would be found who would cheerfully pay from \$20 to \$50 additional rent for such a true and constant enjoyment. If properly arranged originally, by placing a small boiler in the brick work, at the back of the fire-place in the adjoining room, with pipes containing hot water circulating around it in the interior, no extra expense for fuel, or trouble would be required. Even those who do not delight in exotic flowers, would have no objection if it were a greenhouse, where fine sorts of this luscious fruit might be cultivated in the highest perfection.

There is evidently an increasing taste for plants to decorate the parlor, but the greatest hindrance to their flourishing luxuriantly is the want of vertical light and properly regulated heat; in structures such as I recommend both these difficulties are obviated, and they would no doubt succeed admirably. Those who remember Mr. Towse's well cultivated plants, will not require proof of this statement.

I must also, that, in a few years, attention will be

more directed to the exhibition of true taste, whether in laying out the small garden plot around the house, or in more extensive ornamental grounds. For the cost is the same, whether the labor of planting and making walks be expended in a manner consonant to true taste or otherwise; and the principles of true taste are extremely simple and easy of application. Had time permitted, I should like to have laid down a few of these principles, and also to have said a few words on the subject as essential to landscape gardening, of harmony, which should be studied with an artist's eye, both in the plantation of masses and lines of trees, with regard to their mode of growth and foliage, as well as in the arrangement of the colors of the flower garden. I must also leave untouched another subject of great importance; I mean the scientific arrangement of trees and plants in gardens, an object which, when attained, not only increases immeasurably the interest of a garden, but leads even those unscientific minds, which are strongly imbued with a love of order and arrangement, to enjoy and delight in the beautiful domain of the vegetable kingdom.

It would be wrong, however, to devote all of our attention to the ornamental branches of Horticulture; the useful demands on equal, if not a more extensive share. Perfection in the growth of those healthy luxuries of the dinner-table, vegetables, is a main part of the gardener's aim. The value of one portion of these edible plants consists in the perfection of the early shoots, the stems and the foliage, such as the asparagus, rhubarb, the cabbage, the lettuce, the celeriac, &c.—of another portion, it consists in the perfection of the seed, such as peas, beans, &c.—in a third, the perfection is to be produced in the pulpy or cellular mass which covers and surrounds the seed, as the squash, melon, cucumber, &c.—and, in a fourth, in the perfection of the root, as in the carrot, the beet, the potatoe, &c. Now in the consideration of the national various manners, these points must be the chief objects of study, and it is here that experiments on Guano and other manures seem of importance. If, as appears by the plants exhibited, that the action of Guano is great on the stalk and foliage, then its value should be great in the cultivation of celeriac, rhubarb, &c.; if it be found, as appears to me likely, that it improves the seed, then it will be valuable for peas, beans, &c.

All these considerations induce me to think it probable that we are still in our infancy on these subjects, and that the value of horticultural societies, to nurse this infancy to a healthy manhood, will become every year more and more evident.

But if horticultural societies have done much to advance this pursuit, horticultural publications have perhaps done more. Without such publications many of these societies would not now be in existence, and that thousands of individuals who have found innocent and delightful resources and excitement in Horticulture, would have been ruined at the tavern or the gambling-house,—finally, that it is impossible to calculate the advantages bestowed on mankind by the vast diffusion of a taste for Horticulture, which these publications have mainly contributed to produce. I cannot now enter more into detail of these advantages; besides a very brief instance will elucidate them with more force.

In the *Gardner's Chronicle*, published in London 5th May, this year, there is an account of the method of growing melons, &c. at Guisnesco, on the Spanish coast. The beds are formed on the borders of salt water, which at spring tides is allowed to flow in through channels cut for the purpose, thus inundating the roots. Once a year they are covered with about two inches of night soil, which is forked in in the autumn; in the spring a thick layer of leaves is laid on, through which the asparagus shoots rise, in size from three to six inches diameter, or more than double the size of the finest grown here. Nearly the largest head of asparagus I have ever seen, I found during one of my botanical excursions growing wild on the edge of one of the salt marshes at Dorechester in this vicinity, just where the land rises into little hillocks covered with small wood. Here, with the exception of the night soil, nature's operation closely resembles that followed at Guisnesco; the salt water has occasionally access to the roots, and the shoot's rise through the head of leaves with which the natural defence has protected the root. On reading the account in the *Gardner's Chronicle*, all these facts recurred to my memory, and I have no doubt that some pieces of salt marsh, to which, by a little management, the salt water might be occasionally admitted, could be most profitably converted into asparagus beds, which in luxuriance and produce would far surpass many at present in existence.

5. 2 " " horse manure, " 25½ " " 30th, mowed the grass. 31st weighed it," product as in the above table.

the result of the above experiment shows most conclusively the value of ashes as a manure for grass. *Quere.* Is not the value of the ashes chiefly derived from the potash they contain?

All plants of the grass kind require *silicic acid of ash*,"—Liebig's Ag. Chem., p. 200.

The *silica* or *flint* of the soil is dissolved by the ash of the ashes, this forms *silicate of potash*, which is absorbed by the grasses, forming one of their constituents, as found by chemical analysis. Is this the true solution of the question? I leave it to our intelligent farmers to make the right use of the facts.

lora our friend will see has anticipated his wishes.

Foot Rot in Sheep.

WEYBRIDGE, Vt., June 27, 1842.

TR. EDITOR, SIR:—I have delayed sometime in giving you my mode of managing and curing foot rot in sheep, as requested.

Various opinions have arisen about the foot rot in countries as well as here. Some English authors treatises on sheep husbandry ascribe the disease to wet pastures, to the superabundant growth of hoof, &c. &c. I believe none of these causes sufficient to create foot rot. It is a disease that spread only by an inoculation of the infection, which may be introduced different ways. I have seen flocks of sheep to graze for years in different places, side by side; one flock would be troubled with the rot, the other be always clear of it; and I know flocks to be cured of the disease and period to graze in the same low pastures for years afterwards, and not again become infected. I never did of the disease, and presume it was not known on our continent nor the seaboard sheep, until it was introduced here by the Saxony sheep. If low wet areas will create the foot rot, as it has been asserted by Quat and other writers, why was not the disease among us thirty years ago? All the different flocks of sheep are exposed and liable to foot rot if range in the same pasture when any one of the is diseased, or when any of the infected sheep been in it months previous. It may be mysterious ones with some how they came by the disease. It be communicated by driving them along the high- where a flock of foot rotted sheep passed months ere, or by washing them in the same pen where diseased sheep have been washed. In cold weather now then a sheep will carry the disease for months, and but but little lameness, if any. Those sheep that long hoofs and others with very close hoofs, are difficult to cure, and the most liable to be inoculated, because they are more liable to draw the grass between the hoofs on which the infection has been de- Tightly hooved sheep are more subject to friction, and therefore cannot heal as quickly; lambs and lings are more easy to be cured, because the hoofs smaller and more open.

A sharp pointed knife is the best instrument that be used, and blue vitriol is the best and softest ointment that can be applied, of the many kinds I have tried; different mixtures and medicines, as willow bark, oil of vitriol, alum, butter of antimony, saltpetre, corrosive sublimate, &c. &c. Al- Anystringent or medicine of a dry nature is bad, such as quick lime or dry dust of the road, coal, &c. The infection therefore spreads most in

moist lands and in wet seasons, because there is no dry dust or any thing of a drying nature to operate between the hoofs—however it scarcely ever is eradicated from a flock without some labor and external means are applied. I have known it to leave small flocks in a dry season in dry pastures, and also in winter, because if all the infection freezes, it kills the vitality. In England and Ireland they are less subject to frost and their soil is naturally more moist than with us—therefore the foot rot may be expected to be more prevalent.

Before I proceed farther I will inform your readers that I have cured thousands of sheep so that they "staid cured," unless in some instances they were again exposed by infected sheep getting among them. I have now several hundred sheep on my farm that were infected with the rot two years ago, that were then soon cured by the application of a solution of blue vitriol and zig between the hoofs with a swab, after all the infected part had been thoroughly and carefully pared.

The winter season or when we have frosts, is the best and surest time to cure the infected flocks, because all the infection that leaves the hoof is frozen, and is as surely destroyed as would be the infection of small or skin pox. When of long standing it cannot be entirely eradicated from a flock, especially in warm wet weather, unless they are permitted to range in another pasture where there is no exposure after the treatment. When they are to be examined, it is not only a saving in time but labor to construct a trough out of two boards, set up flaring about fourteen inches from the ground, something like a butcher's trough, in which the sheep are placed upon their backs, where they require no other fastening to keep them quiet while the examination is going on. The horn of every infected hoof must be pared off so far as the disease has got under, and all the feet swabbed whether sound or unsound; and if the application be in winter, the medicines should be warm. If thoroughly done by a skilful hand, the rot will be removed, and the foot healed in less than one week. The diseased animals should all be separated from the flock if it be warm weather, and examined again in five or six days. I have known them to become lame in 3 days after they were inoculated. I never knew a sheep of a strong constitution to die with this disease, excepting that in warm weather the infection getting on the body of the sheep when lying down, creates a sore on the body which becomes infested with maggots, and eventually killing the sheep if let alone. I have prevented its raging in warm weather by obliging them to pass through a trough of vitriol water now and then, according to the state of the disease and weather.

As for sheep ranging in a swamp breeding foot rot, puts me in mind of what I have heard asserted by some people, that a man lying in the woods on a bed of leaves for a length of time, would breed fleas. If I had been informed that they would and could thus breed the rhinoceros, I would the sooner have believed them, because the machinery and mechanism would not be so very minute and complicated but of a coarser kind.

Yours very respectfully,
S. W. JEWETT.

Large Cattle.

We saw the beautiful animal mentioned before repeatedly, from his steerage to his oxbood. We advised his making the Grand Tour. A friend of ours, who had resided in England nearly thirty years, and assumed to be an eminent connoisseur in Cattle, undertook to say he would receive no notice there; and a good deal else indicating how easily prejudice warps the judgment: even in intelligent minds. We

are glad that he proved a false prophet, and that the British agriculturist public have so strongly sanctioned our own opinions. This animal was not of the pure blood, but half blood. He was an exceedingly well-formed animal. We were about to speak of his good points, but he was so fat and smooth, it would be difficult to find any points about him but the points of his hoofs and his horns.

The noble ox belonging to Mr. Ruet, of Syracuse, Oneida Co., is of pure native stock: he weighs 4100 lbs., and is still healthy and thrifty. We had his dimensions taken a year since, at the Syracuse Fair, but as he has grown largely since, we prefer waiting for a more recent measurement before we give them. We apprehend that he is destined to bear the palm from all the mammoth oxen on record. Mr. Godfrey's oxen, (of Geneva,) exhibited at the State Fair at Albany, were most remarkable animals, of astonishing size, fatness, and thrift. There were represented as native stock. We cannot however decide definitely on this point. We shall, as is the fashion in Court Gazette, know more about the movements and exploits of all these Great Folks presently, and shall duly chronicle them.—Ed.

THE AMERICAN MAMMOTH OX OLYMPUS.

This astonishing animal was bred by Isaac Hubbard, Esq., in the town of Claremont, State of New Hampshire. He was sold in October 1837, and taken down the Connecticut river to New-York, from thence to Boston; and was imported to England in the fall of 1838 under a heavy bond to Her Majesty's customs to be re-shipped to America in six months. Her Majesty's government was pleased to extend the Bond; at this period his name was changed, and was called Brother Jonathan. He weighed at New London before leaving the country 3600 lbs. He was sold late in the fall of 1838 to a company of gentlemen for a large sum, who exhibited him over most of England. This beautiful creature was exhibited at the Egyptian Hall, Piccadilly, London, seven weeks, during which time 22,368 persons visited him, including most every branch of the Royal Family, and the leading agricultural noblemen and gentlemen. By special permission he was admitted into the great Fair at Oxford as an American Ox, and over four hundred dollars was received in one day. In 1840 he was slaughtered at Horncastle, his weight being 3700 lbs., and it was the opinion of good judges had he been quiet a few months, with good attention, he could have been made 400 lbs. heavier. He was of the Short Horned Durham breed, and in form considered by connoisseurs to be the most perfect model of his kind; color, Dapple Bay. He was calved January 4th, 1832, and his weight at different periods was as follows:

Jan. 4th, 1833, being 1 year old, he weighed 874 lbs
Dec. 23d, '33, " 1880 lbs. gain 11 m 19 ds 456 "
Jan. 5th, '35, " 1800 " " 12 m 13 ds 530 "
Dec. 26th, '35, " 2250 " " 11 m 21 ds 450 "
Feb. 15th, '37, " 2910 " " 13 m 10 ds 560 "
April 4th, '38, " 3370 " " 13 m 17 ds 460 "
" 40, " 3700 "

PROPORTIONS.

Measuring in length from nose to rump, 11 ft. 10 in.
" Height over fore shoulders, 5 ft. 11 in.
" Girth, 10 ft. 9 in.
" Loins, 9 ft. 11 in.
" Breadth of Hips, 3 ft. 1 in.
" Shoulders, 2 ft. 11 in.
" Girth of fore arm, 2 ft. 6 in.
" Height of breast from ground, 1 ft. 11 in.

GREAT YIELD OF HOPS.

Gordon Avery, in the village of Waterville, Oneida county, N. Y., raised this year on 12 acres of land, 29,937 lbs. of hops. He proposes to challenge the world to excel him as to quantity and quality, on the same quantity of land, for \$1,000—separately—quantity without quality, or quantity without quality, or \$300, on satisfactory evidence.

Cattle Show and Fair at Albany--September 27, 28, 29, 30.

We had prepared the subjoined account of this festival for the last number of the Farmer, but though seasonably mailed, it was unfortunately not received in season. Our account must be imperfect for two reasons: first, because we are necessarily restricted in our limits; the second, because having been placed upon the committee for the examination and testing of ploughs, we were, in the discharge of our duties, for nearly the whole of three days exiled from the field, and had no opportunity of doing more than to take a passing glance at the exhibition.

The Show was held at a distance of about two miles from Albany, in an enclosure of more than twenty acres, known and used as the trotting course. A wide and smooth drive encircled the field. The outside of the drive was occupied by a few booths, though the greater part of the booths were without the enclosure; the ground within the drive was entirely devoted to the objects of the Fair. A large wooden building was erected for the exhibition of dairy products, vegetable products, silk, maple sugar, fruits, flowers, small agricultural implements, such as hoes, spades &c. &c., bee-hives, eocooneries, various models of an agricultural character, specimens of the product of the spinning wheel, the loom and the needle, and many other articles of this description, which the reports of the various committees will hereafter describe. There was on the field likewise a large marquee for the offices of the Secretaries of the Society and the Executive Committee, and the tents of a military company were erected upon the field for shelter in case of rain. The threshing and fanning mills were exhibited in the rear of the enclosure; the ploughs, straw-cutters, corn-crackers, sowing machines &c. &c. &c. in front; two or three ranges of pens were formed for the exhibition of the swine and sheep, and calves; and the principal animals were tied to stakes, within and around the circle. The weather for the three first days was never more propitious. The fourth day, devoted to the public sale of animals and goods, was slightly rainy in the forenoon, but no one was seriously inconvenienced. The attendance during Wednesday and Thursday was very large, not less than 8000 tickets of admission having been sold the first day exclusive of those which were given away; and a badge, which entitled the bearer to a free admission at all times was presented to every gentleman known to be from out of the State. The money received at the gate was exclusively devoted to the actual expenses of the occasion and the objects of the Society. The arrangements throughout were excellent; and although, as was to be expected, and, as in such cases was unavoidable, mistakes may have occurred, and omissions may have taken place which are to be regretted, and improvements may have suggested themselves, which actual experience only could point out, yet the arrangements throughout reflect great credit upon the gentlemen who made them and whose laborious services were all rendered gratuitously, among whom, without invidiousness, may be named, Mr. Tucker of the Cultivator, Mr. Prentice of Albany, Mr. Wadsworth of Genesee, President of the Society, Mr. Nott of Guiderland, late President of the Society, Mr. Beament of Albany, and Mr. Walsh of Lansingburgh. To the latter gentleman is without doubt due the honor of laying the foundation of the Society; and of having watched over and assisted its progress with disinterested and parental assiduity. To several other gentlemen, who cheerfully rendered their assistance on the occasion, the agricultural community are greatly indebted.

The show of ploughs was beautiful; thirty-three having been entered for competition and exhibition.

ful construction. The show of other implements was numerous and respectable. The show of animals, especially of the Improved Durham Short Horn, of the Hereford Stock, of Southdown, Cotswold, Leicester, Dishley and fine Saxony sheep, for quality, at least, has probably never been equalled in this country. The admirable Durham stock of Mr. Prentice and Mr. Vail, and the Hereford stock of Messrs. Corning and Southam, the perfect specimens of Southdown sheep from Mr. Rotch of Batavia, of Cotswold and Leicester from Mr. Dunn of Albany, excited universal admiration. Three of the Cotswold sheep of Mr. Dunn weighed together 889 lbs. There were other fine specimens of sheep, the names of whose owners we could not learn. The swine we had no opportunity of inspecting; but Mr. Lincoln of Worcester, one of the committee, celebrated for his Porcelain skill, will give a full account of them in his own good humor. The horses were on the ground only in our absence. In specimens of native stock, as far as we could see, there was an almost entire deficiency, which was much to be regretted. In fat oxen, though the number was small, yet the show was magnificent. Mr. Ives' cattle were excellent; but the ox of Mr. Rust of Syracuse, and the two oxen of Mr. Godfrey of Geneva may challenge the world for their equals. The live weight of Mr. Rust's ox was 4100 lbs, and he is still gaining rapidly. The famous cow from Maine, for her size and fatness, of her kind probably the most extraordinary animal ever seen, was there for private exhibition. One yoke of Devon working oxen attracted universal attention and admiration. In appearance we have never seen their superiors. But we cannot now farther particularize.

The trial of ploughs took place on a field distant half a mile from the show-field. Fifteen different ploughs were entered for examination. The points to be ascertained were mainly the power of draft required to move the plough, and its general construction, durability, and expense. The dynamometer was applied to each plough, and four different observations taken and the whole compared; but from the imperfection of the instrument, from the nature of the power applied, different teams and different harnesses being necessarily used in different cases; and from the impossibility, with the imperfect arrangements which had been made, of making the trial equal to all the competitors, the committee determined to submit to the competitors themselves, the question whether a decision on the partial and unsatisfactory grounds which the committee possessed, should then be made, or whether the whole matter of premiums in this case should be abandoned until another year, when the society would be expected to make such arrangements for the trial, that the committee might arrive at a fair decision; at least one which would satisfy themselves. The competitors perceiving all the difficulties of the case and knowing how very important to their interests a decision would be, expressed their unanimous desire that the decision for this year should be omitted; and their request that the money designed for premiums this year might be applied to the increase of premiums for the same object at the next show.

The ploughing match for a sweepstake of 100 dollars came off on Thursday forenoon. Ten teams entered the lists; and ploughed each one quarter of an acre. Nine of these were teams of one pair of horses; one, a team of one yoke of oxen. A greater part of the ploughing was admirable; and for its skill and beauty could not be exceeded. The different lots were merely numbered; and no name was known to the judges, who were not on the ground until the teams had left. The points to which their examination was directed, were simply the depth and width of the furrow, and the parallel lines or exactness with

clusively the majority of the committee decided in favor of lot No 1: John Keeler, who drove the entered by Mr. Hillhouse. The plough used in case was from the plough factory of Ruggles, No. & Mason at Worcester, Mass. one of the most extensive establishments for the manufacture of ploughs other agricultural implements in the country. The grounds of the judgment of the committee were extremely limited; but were presented to them by managers. What would have been the decision of the committee had the whole subject of ploughing, the skill of the ploughmen been taken into view have no means of knowing; but the result is have been different.

The society met on Thursday afternoon at the hotel, to listen to an admirable address from Gov. Seward. Its subject was general; the importance of agriculture, its economical and political bearings; its improvements; its debt to science and its prospect of advantage from science, and the value of education to the agricultural classes. In relation to these, though brief, it was sensible, judicious, and profound in sentiment, and perspicuous, beautiful, and new in its style and illustrations. It commended universal attention and respect.

The farmers and others interested in agricultural improvement held a meeting on Tuesday evening at the room of the Young Men's Association, a Wednesday evening a very crowded meeting in the Capitol, for the discussion of subjects connected with agriculture. Judge Sackett of Seneca Falls presided. The subjects considered were the condition of the agricultural classes, their just claims to protective patronage from the government, and especially importance of provision for the education of farmers, the establishment of agricultural schools at permanent farms. The meetings were addressed by Mr. Majum of Boston, Mr. Johnson of Onondaga, Mr. Holcomb of Delaware, Mr. Miller of Virginia, Mr. Peters of Pennsylvania, Mr. Baldwin of Syracuse, and Mr. Stone of New York. Other gentlemen participated in the discussion. The committee of eight, one from each Senatorial district, was appointed to draft a memorial to the Legislature on the subject of Agricultural Education. Meetings were conducted in the best spirit, and evinced a strong and enthusiastic interest in the education and improvement of the rural classes.

An agricultural dinner was given at the Knickerbocker Hall on Thursday evening, where a large party of gentlemen enjoyed, in a high measure, the festivities of the occasion. The sitting was protracted a late hour, and rendered interesting and agreeable by a very handsome and appropriate address from the President of the society, Jas. S. Wadsworth, by speeches and sentiments from Lieut. G. Bradish, Gen. Tallmadge and Col. Stone of York, Mr. Nott, Dr. Beckman, Mr. Vail, G. O. Choates, Mr. Barnard of Congress, Mr. Baldwin of Onondaga, Mr. Marx of Richmond, Dr. Thompson of Del., by a speech in Dutch Judge Van Bergen of Coxsackie, and by a most interesting, loyal, speech from Mr. Ferguson of Dutchess County. Mr. Ferguson, by his excellent humor, the waters of good fellowship, active, bright sparkling through the whole evening. Mr. Albany Co. in this matter, likewise played hand. The company separated in good humor, the best wishes for each other's prosperity, and bright hopes of a repeated interchange of kind feelings and sympathies at the next anniversary.

RAILWAY SPEED.—The lines upon which trains travel at the greatest speed are as follow: Average speed, exclusive of stoppage. North Eastern, 36 miles per hour; Great Western, London and Brighton, 30, Newcastle and

We should like to give all the speeches made at an agricultural dinner at the Knickerbocker Hall on a 25th ult., but our restricted limits forbid; but there was so much heartiness, cheerfulness and good sense in the speech of Mr. Ferguson of Dundee, L. C., that we give his remarks on this occasion, a summary reported in the Albany Argus.

Mr. Ferguson, of Canada, rose to respond on behalf of the visitors from other states, to a very handsome compliment, he said, which the gentleman at the other end of the table had just paid to him. But before I deliver a word or in just (said he) I beg leave, in the spirit of good fellowship, to ask if there is in this room the illustrious chairman of the committee on agriculture? [Laughter.] If yes, if that gentleman is present I will not read one word more until I hear him.

[Renewed laughter.] This allusion there was to Mr. Lincoln on Thursday afternoon, that kept the audience in a roar from its beginning to end. The meeting allusion to it by Mr. F., called up a vivid recollection of all Mr. L.'s very happy points. He is not present," continued Mr. F., in a tone of disappointment. "I then, gentlemen, will tell you why. It is to save his name. [Laughter.] No, gentlemen, I address you as fellow farmers. I have among my fellow citizens, but fellow farmers. As farmers I beg leave first to express to you my deep sense of gratitude for the honor conferred on me, a backwoodsman of Canada, in being permitted to be present at such a meeting as this, and for the pleasure and instruction I have received there. And now, gentlemen, I forget it, that this office of mine is a very difficult and thankless one, and that you may discharge your duty more so faithfully and conscientiously, you are perfectly sure not to give entire satisfaction. At the same time, they who have undertaken that duty have a right to call on the society for whom they act, to support them in their awards, and to see that no undue remarks are made on their judgments."

Having said thus much about my fellow judges, permit me to rub my eyes and look about me and think what a glorious meeting we have had—what an exhibition of states—how great New-York is. Why, ten years ago I would have said all this means to have produced any thing like what we have seen. The result is not in existence here. But it is now, and we will not let it pass. In the great state of New-York particularly—I don't say gradually, I say, but gradually, of circumstances, and one of the happy results of these meetings is to bring the rich into contact with the honest farmer, and to teach the former what nobility and independence is, and where it is to be found. [Cheers.] If independence is to be found on earth—its independence is to be secured, it is within the staff of the plough. There it is. The honest farmer comes into the city, and is bewitched and enraptured by the splendor that meets his eye on every hand. But, gentlemen, what sort of splendor is that? A single shawl, a cravat, a sword, and down they go like nine pins. [Laughter.] The farmer has always a fine reliance. He has his pork barrel and his corn barrel, and his good old wife and children depend on them—real, true, and solid. [Cheers.] Nay more—there you find honest morality, religious virtue, [Cheers.] in their proper form. Who does not know that man, mixed up with them in the excess and excitement of busy life, no more pretends what it is to be an honest farmer, living on his paternal acres? But we must not forget that we were made, thank God, to help one another. We are all links of one great human chain. And I say perdition to the man that would break one of them. [Cheers.] I want to see all men equal in their rights. I live under a monarchical form of government—you may be a republican. But I say we are all brothers. [Cheers.] Mark that—we are all sons of the same common stock. [Cheers.] We are of one common family. I say without fear of contradiction here, that America and Britons have the love of liberty in their hearts. [Cheers.] I say without reference to our living under a Queen or a President. I hope there is no high Canadian Tory present that will go home and tell me. [Laughter.] Do I mistake me—I am a true, loyal, British subject. [Rings of laughter.] What I meant to convey was this—that the great outlines of the two greatest nations in the world are the same. We have our property and lives secured by the habeas corpus and the trial by jury. That is no man's matter. We have an executive head. We have a house of Peers—or a Senate—call it what you please. And we have representatives of the people.

There are the great leading outlines of the constitution of both nations. Why allow anything to make in our hearts, who have every reason as reasons, to go together? who can, at their will, play into each other's hands? I go with the gentleman opposite (Mr. Thompson) as to free trade. But that is a subject for a second and a difficult for me to enter on here. I beg pardon for intruding too long. [Cheers of "go on," "go on," "go on."] These few lines for a long time set on my lips, and so I don't know how to say down. [Laughter.] Because if I had the talent to give vent to it, I am overflowing with matter. [Laughter.]

It has just flashed across my mind, gentlemen, what progress this world is making, and this country in particular. We can know nothing of it. I need not ask here—for who has not read Washington Irving? Who has not read Knickerbocker? [Laughter.] I should like to see how Rip Van Winkle would have fared if he had opened his eyes, after a thirty years' slumber, on the Bull's Head yesterday or today. [Laughter.] He would have seen his eyes a double size, to see the more, a double since he went to sleep down the road. And which would he not have done to have been told that two great nations, by the simple power of steam, had been brought within a fortnight's sail of each other? To see a mother and child, hitherto separated by distance and nothing, brought together, as it were, into close proximity? For there was a time when an American in London was treated as a wild beast, and the Briton came over here, why he was the Devil and all. [Laughter.] This is not so now. As we come to see each other, we come to like one another better than ever before. I have said already, I am a loyal Briton, and I rejoice; I cannot tell you how I rejoice—in the present state of affairs between the two countries. [Cheers.] I assure you gentlemen I am not alone in this. Hundreds and thousands of British hearts are beating with joy at the thought, at the prospect of a termination of all our difficulties. I sincerely hope, gentlemen, that I have no objection in the world, to saying that the Americans in the field—say, on the tented field of the Bull's Head. [Rings of laughter.] That is the field for me. No drilling, if you please.—but the drilling of turnips. [Laughter.]

Gentlemen, I hardly dare trust myself to speak of that glorious man—the Father of this country—to whom allusions were made so long ago just now. Gentlemen, I revere the memory of Washington. If ever there was a Patriot on earth, Washington was the man. [Cheers.] I visited Mr. Vernon not long since, and I am not ashamed in this company to say, how my heart swelled at the sight of that great man's tomb. I could not help repeating, to the astonishment of the man who showed me the grounds— "O how I wish the brave was back to rest." By all the country's wishes, indeed! Who, spirit with dewy fingers said, But you took that hero's hollow tomb, and made it a mere shell for the bones of a dead man. Then I said, "You have been a great deal wrong." But my hands, the truth is true. In fact, I am not ashamed to say, "Then I am wrong, and you are right." To those of us that weeps on this day— And I repeat—

Gentlemen, I forget the rest of it. [Cheers loud and long.]

Mr. F. touched briefly in English on the subject of agricultural education. He felt totally incompetent to say how the subject was to be brought about, but he would say this, that farmers might be educated to do high, and might be kept in their proper position. The point to be aimed at was that much of high talent should be acquainted with the prime and detail of husbandry, and that men who understood the mechanical details should be ignorant of science. He knew an individual, who, like many in London, had acquired a fortune in business, determined to have done with the shop and buy an estate. He closed his books, and down he went to the country. His first inquiry there, as an Englishman's was not to be, was where the nearest butcher's was? [Laughter.] He was told that every gentleman killed his own mutton. "D-d dirty work," said he, "but I'll try." The man knew no more of a country life than the weather-cock on the steeple. [Laughter.] Mr. F. concluded by giving

Domestic Manufactures—Plenty of fuel for children and stock, and the good honest house wife that beats them. [Three cheers given standing.]

Prevention of Stunt.
Percher's (German) Encyclopedia of Agriculture gives the following as the celebrated receipt of M.

Schultz, of Duerri, in the province of Juchre, (Prussia,) for preparing seed wheat so as to prevent stunt in the crop. So efficient was Mr. S. in the efficiency of this method, that he offered a standing reward of a dollar, for every load of stunted wheat found in his field.

For every 500 lbs. of seed wheat, take one lb. alum, 1 lb. copers, 1 lb. sulphate, and one lb. verdigris. Pulverize these ingredients and dissolve them in a sufficient quantity of boiling water. When the solution has become cold add as much more water as will be required to moisten the whole thoroughly. The heap should then be turned several times within the ensuing 24 hours, and well mixed; and it is ready for sowing.

Self-Regulating Stove, invented by E. Foot Junr., Seneca Falls.

A remarkable property possessed by this Stove, is that of governing its own heat, so as to maintain, without variation, the precise degree which may be required.

At the top and near the upper part of the Stove, is placed a brass rod—straight and inflexible. Should the heat rise too high, the expansion of the rod, acting on a lever by which its motion is much increased, is made to close a damper that governs the admission of air. Or should the heat fall too low, the contraction of the rod opens the damper and lets in a full draft. A sufficient quantity of fuel being placed in the stove, its burning is held in constant check by the closing of the damper—consuming no faster than a want of sufficient heat to keep it closed permits: Thus is kept an uniform heat.

The manner in which the degree of heat at which the stove shall maintain itself, is changed, is equally simple, though not so easily described: By merely moving a point, a different degree of expansion, and of course different degrees of heat, are required to close or to open the damper. A dial-plate, like the face of a clock, forms a part of the front of the stove. On this is marked the different degrees of heat required,—and the index being turned to a degree, the stove will immediately adapt itself to that point, and there remain without variation.

And the invention stopped here, there would have been left a defect which probably would have destroyed its usefulness. Should the heat rise so high as to close the damper, and if it then any cause continue to rise above that point, some part of the structure must necessarily give away, or else be so loosely and imperfectly in design as to allow such a variation—or should the heat continue to fall after opening the damper, the same difficulty would be presented. We regret that we cannot show drawings, convey to the reader the simple manner in which these difficulties are removed. The moment the heat should rise above the point of closing the damper, the rod disconnects and detaches itself from it, and so remains until the heat returns again to the same point—when immediately it re-connects itself, and resumes its appropriate duties. Or should the heat fall after opening the damper, the rod becomes disconnected until it returns to the same point. This point, more than any other, will strike the attention of the mechanic. It is said to be before unknown in mechanics, and is as remarkable for its simplicity as its ingenuity.

The stove has various other valuable qualities. It is estimated that from three-fourths to five-sixths of the heat from the fuel consumed in an ordinary stove, is carried off by the current passing through it to the chimney. In this stove, no more air being admitted than is necessary to sustain the combustion, very little current is made, and nearly all the heat is expended in the room. And besides, the smoke and cinders, being long retained in contact with the fire, are mostly consumed.

The fuel in this stove being permitted to burn no faster than is wanted, enough may be put in at once to last 12 or 24 hours. Wood is converted into a bed of charcoal, which gradually consumes, but no faster than is required. A person may go from home, and leave his stove burning the day, or through the night, and when he returns find it at precisely the same temperature at which he left it.

Remedy Against Frost.

It is recommended, in some of the French agricultural papers, to deposit some wet strawy manure in the forks of a fruit tree when in blossom, to protect the fruit from frost. If applied in the evening, it is said, that, should frost occur in the night, it will be visible on the upper surface of the manure, but the fruit buds or blossoms will wholly escape injury.

ROCHESTER, NOVEMBER, 1842.

AGRICULTURAL INTELLIGENCE.

The Monroe Co. Agricultural Society held their Show and Fair in Rochester, on the 25th and 26th of October. It was numerously attended on both days, and showed the zeal of the farmers, which was not cooled off by driving for miles through mud nearly to the hubs of the wheels, the rain of the preceding night having left the roads in a most miry condition for the season. This state of the roads undoubtedly prevented the bringing of many articles and animals, bired and quadraped, to the Fair, which would otherwise have been there; but the show in all respects was creditable to the county, and the city was crowded with farmers, their wives and children both days of the Fair.

We shall leave the several Committees to speak for themselves and give them on another occasion ample room to be heard. There were several highly improved animals and some excellent native stock among the neat cattle. The magnificent Stud Horse of Mr. Weddle, a horse of most remarkable size and power, and designed for labor, attracted universal admiration. A team of four yoke of oxen from Mr. Ayrault, and some other cattle from Perrinton, and other places, of native stock, and of a cross of the Durham with the Devon, would have done honor to any show in the country. The Leicestershire Swine were there likewise, in their glory, fairly distancing the Berkshire; and a family of pigs, five months old, which, within our knowledge, could hardly be surpassed for size, thrift, and beauty.

The show of vegetables and fruits, though somewhat limited, yet in quality we have never known equalled. The cabbages, some of them weighing 31 lbs. each, the sugar beets and mangel wortzel, the carrots and turnips, and the celery and salsafy and apples were magnificent. The products of female industry and skill were numerous and beautiful. If the county of Monroe has many girls as skilful and industrious as the works of some showed them to be on this occasion, she is eminently rich in the best of all products. If one in particular, whose numerous articles of exhibition were of singular beauty and displayed extraordinary industry and taste and skill, but whom we should deem it indecorous to name, is not inquired after early by some of the young farmers of the county, they at least should have a premium for their obtuseness and be honored with a fool's cap and feathers for the next anniversary.

Some axes and pitchforks from the factory of Mr. Barton of Rochester, were of exquisite finish, as also were some ploughs from the machine shop of Ruggles, Nourse and Mason, at Worcester, and Charles Howard of Hingham, Mass. The ploughs may in all respects be safely compared with any made in the country. The number of articles exhibited were limited, but excellent of their kind.

The ploughing match came off on Wednesday about two miles from the city in the presence of a large concourse of interested and grateful spectators. Seventeen horse teams entered the list, and no one was allowed a driver. The land measured 1.4 of an acre. The depth prescribed was 5 inches; the width of the furrow six feet. The time allowed, 60 minutes for horses; 75 for oxen; but racing was wholly pro-

scribed. The work throughout was well done, some excellently well done, though the land was not favorable to smooth work. The report of the committee will be given in full. An iron plough called the Buck Eye, with a curved beam, appeared to move with extraordinary lightness and ease, and made very good work. Howard's plough, for its excellent work, maintained the high character which it has for years had in Massachusetts, where it is known, as one of the best ploughs ever put into the ground.

The customary address was given in the afternoon and the premiums announced, excepting on crops, which are reserved for the winter meeting; and the members of the Society separated, after a gratifying and friendly intercourse, with stronger convictions of the importance of improved agriculture and a quickened zeal for its promotion. The Society was honored by the presence of several distinguished persons and friends of agricultural improvement from the neighboring counties, and it is hoped that at the winter meeting in Albany of the State Society, such mutual arrangements will be made in regard to the times of holding the County Shows on separate days, that it may be in the power of the farmers of different counties to exchange their civilities, which may be as improving, as gratifying to the parties concerned. The shows should begin early in September, and not as now be all crowded into October.

Ontario County.

Ontario Co. Agricultural Show and Fair was attended on the 18th and 19th of October. The 18th was rainy and unfavorable, still the exhibition of valuable animals was more numerous than has before been presented in the county, and the stock of a better description and in higher condition.

The ploughing match was attended on the second day; twenty-three teams entered for the competition. The contest was close, and the judges much at a loss to decide among ten of the ploughmen. An hour and a half was allowed for ploughing a fourth of an acre of land with horses. The first premium was awarded to Silas Aldrich, Farmington. The second to Wm. Otley, Phelps. The third to Charles B. Meek, Canandaigua. The first premium for ploughing with an ox team, the same amount of land in the same time, was awarded to D. C. Bates, Canandaigua. The second to John H. Wheeler, East Bloombfield. Other ploughmen are mentioned with strong commendation.

We should give the whole list of premiums but cannot afford the space. The products of female industry and skill are represented as uncommonly numerous and beautiful. This is what we should expect in this highly cultivated and intelligent county. The specimens of Ontario Co., women, whom we have had the pleasure of seeing, would be all of them regarded as premium specimens in any part of the country, which we have visited. We only say of the Ontario Co. men, that we wish they may be worthy of their wives. This would be glory enough for them. We would not imply that they are not.

We were glad to see the commendation bestowed upon Hatch's broad cast Sowing Machine, for sowing all kinds of grain and plaster; we believe it every way deserving. We have seen several fields sown with it with great exactness and success. We have the testimony of several excellent farmers in its favor, to which we shall hereafter refer. It is of cheap and simple construction, and not liable to get out of order. For the purpose designed, we know no better machine. Mr. Hatch is a resident of Rochester, N. Y. We regretted that prior engagements at other places prevented our attendance at the Canandaigua Show. In the fertility of its soil, in the beauty of its scenery, in its neat cultivation, in its improvements and the intelligence and elevated character of its population, we be-

lieve it is exceeded by no part of the country. The address of Myron Adams of Bloomfield, is much commended for its good sense and practical character. We hope, through our columns, to have an opportunity of furnishing to our readers the whole, or the most valuable parts of it.

Niagara County Agricultural Society Show and Fair.

This was held at Lockport on the 18th and 19th of October. We had the pleasure of meeting the Farmers of this fertile county on the first day. The day began with rain and so continued until the afternoon. Any one, who has seen a half drowned rat or a game cock after he has been dilt in a tub of cold water and left to drip, knows how crest fallen he seems, and what an extinguisher or damper of all pride and ambition such a thorough wetting always proves. If small things may be compared with great, we could not but be reminded on this occasion of an account given us by a distinguished gentleman of this country, who was a guest at Lord Elgin's Tournament in honor of the young Queen, when the rain came down in torrents and the plumes of the gallant Knights hung like wet rags over their shoulders, the noblest ladies of the land were glad of the shelter of even a cotton umbrella, all the gay pride of rank and title was absorbed in the general desire "to save himself who can," and even the brilliant banquetting table in all its profuseness and splendors was deserted, for there was no other way of keeping the fair and sparkling sandals out of the water but by sitting on the benches after the Turkish fashion with their feet under them, a position which, besides its awkwardness, involved the peril of losing the centre of gravity and incurring a general splash. The day and field at Lockport were in some respects not unlike. As to shaking off the dust of your feet, though one may have felt ever so uncomfortably towards the good people of Lockport, it was out of the question; one could hardly shake the mud off unless the foot went with it.

The farmers of Niagara Co., however, turned out in great force. They are no hot-house plants. The show of cattle was quite numerous. Some excellent animals of the Improved breeds and some first rate specimens of the Dishley, Cotswold and Leicester sheep as well as of the fine woolled varieties were exhibited. Some excellent horses and colts were likewise on the ground. From appearances we think we have reason to infer that in no county in the State, all circumstances considered, is the spirit of agricultural improvement more life than in this rich and beautiful county. Our engagements prevented our remaining during the next day for the exhibition of agricultural and horticultural products and domestic manufactures, but we anticipate the pleasure from some friend there, of a full account.

Genesee Co. Agricultural Show and Fair.

This was attended on the 20th and 21st of October, at Batavia. We had not the honor of being presented either for exhibition or premium among the live stock on the first day; but we were on the ploughing ground in due season, on the second. The attendance was very numerous and the ploughing respectable. Three teams only entered, but they displayed a laudible ambition to excel. This is certain to carry them forward in this first of the farmer's arts. These ploughing matches deserve, in the highest measure, the encouragement of the farmers, as they have been found, whenever employed, among the most powerful means, not merely of improved skill in ploughing, but of general agricultural improvement; because they bring the farmers together under circumstances where their feelings and ambition are strongly excited; and this excitement extends its healthful influence to all branches of rural industry and emulation.

The perfection of the art of ploughing is only to be

seen when an Englishman or Scotchman, trained to it from his childhood, gets between the stiffs of the plough, and, after setting the noses of his horses in a right direction, and putting the beam of his plough to the same point, follows on, turning up the soil every where at an equal depth, with an equal width of furrow, and laying it always at the same angle of inclination and marking it out as exactly as a chalk-line would mark it, and finishing it as perfectly as if it had been done by an experienced hand with a spade. He leaves no haulks, no unturned, no half-turned, no broken sods, and exhibiting a piece of work as neat and as handsome as a newly ironed and plaited shirt ruffle or muslin cape, when it comes from the ironing board of a skilful housewife, ambitious to show off her spouse to as much advantage as he appeared on his wedding night. This we call ploughing, and to this perfection there is no reason why, with proper encouragement and effort, we Yankees should not come at last, and all in due season.

We were told by those, who were perfectly competent to judge, that the show of animals the day previous was numerous and excellent; and so likewise of agricultural products. When next it happens, as was said of Gilpin's ride, "may we be there to see." A numerous and highly respectable audience crowded the Court House after the ploughing match to hear words of encouragement as to the improvement of this great art; and the whole occasion was such as to infuse new zeal and courage into those, who have at heart the advancement of this unquestioned and unquestionable object of human comfort, civilization and improvement.

Cayuga Co. Agricultural Society.

The Cayuga Co. Agricultural Show and Fair were held at Auburn on the 12th and 13th Oct. We had the pleasure of being there on the first day and regretted the necessity of denying ourselves the gratification of witnessing the exhibition of agricultural products and the fruits of the garden and the ploughing match on the second day. The show of animals was small but there were precious specimens of the most improved Stock presented by Mr. Sherwood, Mr. Dill and others. Mr. Sherwood's Stock is splendid and some of his animals are perhaps not surpassed in the country. His celebrated bull showed himself in our sheet some months since, and he has about him a stock quite worthy of him. Mr. Dill's haifer exhibited her fair form and figure at the State Fair and received the deserved compliments on the occasion.

It is impossible to particularize in this case; and we shall wait for the official reports. There is a great omission in almost all these cases of exhibition, and that is the want of proper labels on the pens. When an animal is presented for show, his name, age, stock &c. and his sire's name and his owner's name should be placed on a label on his stake or pen; and if a cow, her product and qualities as well as the other circumstances mentioned above should be stated. At present, there is nothing of this and in most cases no one present to give any information. A considerable number of fat cows were shown and to much advantage.

We had the pleasure, if indeed pleasure it can be called, a sad pleasure in truth, of visiting the State's Prison the ensuing day. The condition of its inmates is probably as good as such wretchedness can be made, though dreadful at best. They are well fed, well clothed, and treated with kindness; but the misery and anguish of being thus "buried alive," we may imagine, can be very little understood by those of us, whom God in his mercy has saved from so wretched a lot. The manufacture of silk is carried on to a considerable extent in the prison and with much success. The articles manufactured are chiefly sewings of an excellent and constantly improving quality; the weaving of silk has been commenced under

favorable auspices. We are promised from the intelligent Superintendent, Henry Polhemus, a detailed account of their operations. The greater portion of the material manufactured has been of domestic production, and \$3,50 to \$4,00 are paid for cocoons. Here is a good home market for all that may be produced.

We were led to reflect with unmingled pain upon the suicidal policy which the State has seen fit to adopt in respect to these unhappy victims; not so much on account of the pecuniary loss which the State must suffer by the actual want of employment for a large portion of them, which they must sustain experience under the new system; but far more for the inhumanity which prohibits in all cases the teaching of these miserable beings some useful trade, by which in the event of their being returned into society they may have the means of getting an honest livelihood. In our humble opinion the State could not have passed a more cruel act than to deny this small boon to these miserable men, who, if any upon earth, are indeed objects of true pity. The clamor about State Prison monopoly is about as worthy of notice as if the tailors and washerwomen in Auburn should complain, that the State provides for making and cleaning the clothes of the convicts instead of giving the job to them. If any thing should have been done it should have been not to prevent these people from laboring and not to refuse to teach them a trade, but to charge their labor and the products of their labor at the same rates as are charged out of doors. For ourselves however, we cannot see that the State was bound to do even this. Open competition is the life of all business and the very element of improvement. This legislating for particular trades or parties is unjust to the community; and the manufacturers of silk have as good a right to demand that the State shall abandon this important branch of business as any other body of tradesmen that any branch of manufacture whatever should be given up in the State Prison. Many of these poor fellows, among whom we may admit there may be some of the most profligate and abandoned, are more objects of compassion than of condemnation; and how can we under the pretence of administering a reformatory discipline be willing to turn them adrift upon society without character, without money and without any honest means of livelihood, that they may be secured against those temptations to crime, which may otherwise, soon bring them back to their solitary dungeons. The cry of such inhumanity must not go up to Heaven. The State, we think, cannot too soon retract its steps. These men, wretched, criminal, and abandoned as they are, have in that very condition the strongest claims upon public compassion and care.

Auburn as a town or village has few superiors. Its wide and well-built streets, its spacious and splendid blocks of stores filled too overflowing with goods, its handsome public buildings and hotels, and its many extraordinarily careful and beautiful private residences, render it peculiarly attractive as a place of visit or habitation. This is our only visit since 1825 excepting the pigeon-flight through its suburbs by the rail road cars. Its progress and improvements are most remarkable.

Wayne County Agricultural Society

Held its annual Fair on the 5th and 6th days of the eighth month, at Palmyra. The increase of general interest was shown by the many hundreds of our most intelligent farmers and other citizens who were present, from all parts of the county.

The first day was devoted to the exhibition of domestic animals. Not less, probably, than a hundred head of cattle were upon the ground, including several full-blood Durhams, many half-blood, and some very fine specimens of native breed. It is to be regretted that the reports of the Committees did not specify the breeds; among those however, who exhibited the best Durham cattle noticed, were Wm. R. Smith, John

Baker, and Thomas Wright of Macedon, Wm. Swails of Solus, Dr. Button of Newark, James Dunn of Lyons, and others. Several very fine horses were also exhibited; the premiums were given to C. D. Culver of Macedon, for the horse "Young Turk," and to Dr. May of Palmyra, for the Morgan horse "Tiger." Other fine horses were exhibited, among which were the celebrated imported horses Alfred and Samson, the former belonging to Thomas Weddle of Rochester, and the latter to John Robinson of Palmyra. There was a marked difference in the collection of sheep and swine, although some beautiful Berkshires were noticed, and some fine specimens of sheep of Leicester, and Saxony breeds.

The second day was occupied with the exhibition of Fruit and articles of Domestic Manufacture. These were exceedingly creditable, though the collection was moderate. Several very fine fruits were noticed—the peaches were far better than any at the State Fair at Albany; and some of the apples were very excellent. Pears and grapes were quite deficient. Among miscellaneous articles, were noticed very fine specimens of carpeting, flannel, and hearth rugs; excellent cocoons from E. B. Blakesly, Newark; some very fine vegetables; and a highly finished two-horse lumber wagon, varnished, but unpainted, showing the surpassing strength and excellent quality of the timber employed in its manufacture, from Sherman & Crandall of Palmyra.

The ploughing match was on the morning of the second day, and afforded great interest and gratification to the many hundreds of spectators who were present. The ground was a sward, the soil a sandy loam, the quantity of land for each team a quarter of an acre, to be ploughed full six inches in depth, in one hour. The excellence of the ploughing, or at least a part of it, excited the admiration of all; work of equal quality, it is believed, is rarely witnessed on similar occasions. The first prize was awarded to John Robinson of Palmyra, (B. Brown, ploughman,) and the adaptation of the Samson breed of horses, at least for ploughing, was most satisfactorily shown by the ease with which a pair of half-blood, only three years old, plowed their quarter of an acre, in about fifty minutes, and took the first prize. It was observed with satisfaction, that no inducement was given to hard driving, by offering a reward on speed, a specified time merely being required.

The report of the several Committees, being in most cases unaccompanied with any statements of the peculiar management, or of the breeds, which drew the premiums, but merely of the names of the successful competitors, and only of local interest, and are consequently omitted.

On the whole, a greatly increased zeal is awakened in support of the Society, and of the Agriculture of the county, and there is every reason for it. Wayne county possesses great advantages, and remarkable susceptibilities of improvement. With a rich sandy-loam soil, not so heavy as to bake nor so light as to lack strength, and a marly, fertile sub-soil; with occasional beds of peat and marsh-muck, scattered over its surface, and sometimes shell marl, affording immense resources in the manufacture of manure,—there is every inducement for skill, enterprise, industry, and thorough farming. And in a horticultural point of view, the advantages are not inferior, for in addition to the excellent adaptation of the soil, the climate is greatly softened, and severe frosts, destructive elsewhere, are prevented by the proximity of Lake Ontario.

Then let her "GO AHEAD!"

Note.—It is proper to say that in noticing meritorious animals and articles above, others may have been equally so, which the imperfect observation of a single individual may have overlooked. Those matters only most interesting to the writer are noticed, and very few have no partialities. J. J. T.

No 13. A fine Berkshire sow and two pigs, owned by Mr. Gibson of Albany.

No 14. Another fine Berkshire sow and four pigs, owned by the same.

No 20. A splendid breeding sow of the Berkshire and Cheshire, owned by Mr. Fox of Albany.

MACHINES, &c.

Threshing—1st prem. to John A. Pitts of Albany; 2d, to Mr. Stafford of Syracuse; the diploma to Mr. Bostwick.

Straw Cutter—1st prem. to Mr. H. Wey, Worcester; 2d, to J. Standish, Fishkill; 3d, to Bots and Harbott, Richmond, Va.; 4th, to R. Sinclair & Co., Baltimore.

Horse Rakes—2d prem. to I. Dornier, Castleton; 3d, to Lewis Simmons.

Fanning Mills—1st prem. to I. E. Grant, of Schaghticoke; 2d, to Plimpton W. Dickie, of Phelps; 3d, to J. L. Ballack, Guilford.

Harrows—1st prem. to Marcus Adams, Monroe; 2d, to Christopher Proctor of Bethlehem; 3d, to D. Caley of Bethlehem.

Cultivators—1st prem. to J. H. Koons, Rensselaer; 2d, to Ruggles, Nourse & Mason, Worcester; 3d, to Elmhurst Elmer, Delin.

Corn Crushers—1st prem. O. Hassey; 2d, R. H. Sinclair; 3d, James Murray.

Corn Shellers—A diploma to J. A. Whitford, Saratoga Springs.

Hay and Cotton Press—A premium to W. S. Jacks, of Catskill.

Thermometer Churn—A premium to Mr. Crowell, of Lime Rock, Ct.

Self-acting Cheese Press—A premium to Collins and Stone.

Hoes—A diploma to H. Clark of Rensselaer.

Pumps—A diploma to Augustus Thayer, Chatham.

Horse-Shoes—A diploma to Henry Barden, of Troy.

Pronging—A discretionary premium or silver medal to Daniel Caley of Bethlehem.

We understand that a very superior Ayrshire Bull, Cow, and Calf, recently imported, were exhibited at the Fair, by the Hon. A. Van Bergen, of Coxsacke. Had not the several committees been misinformed as to the breed of these animals, they would have received premiums beyond all question. We are glad to learn that they have been purchased by our fellow citizen, Joel Rathbone, Esq.; and we congratulate the farmers of Albany county upon this valuable addition to the already numerous herds of imported cattle in our vicinity.

Among the horticultural exhibitions was a case of Fruit from the garden of A. T. Van Slyke, Esq., of Coxsacke, Greene co., containing six splendid bunches of foreign Grapes, the Black Hamburg, and eight very large Peaches, taken from a seedling tree of two years' growth, the largest measuring nine and a quarter inches, and the smallest eight inches in circumference.

Jones' Patent Silk Reel.—Amongst the results of inventive genius exhibited at the Fair of the Agricultural Society, there was none with the simplicity, compactness and beautiful operation of which we were better pleased, than the *Silk Reel* of Messrs. A. B. & W. H. Jones, of Manchester Conn. The whole machine does not exceed a cubic foot in size, and is novel both in its construction and mode of communicating motion, having for this purpose neither gearing, belting nor banding, and hence is not liable to get out of order. It winds the silk from the cocoons upon small barrels, and runs two threads at a time, which cross each other between the first and second guides, precisely like the Piedmontese Reel.

When dry, the silk can be slipped off from the barrels in small circular skeins which will preserve their shape to be packed and transported any distance, and can at pleasure be unwound with as much facility as yarn is taken from the ball, and without any liability of breaking or losing the end. It thus virtually performs the two-fold operation of reeling and spooling at the same time, as it is doubled and thrown immediately from the barrels in small circular skeins. Another recommendation of this reel is the expedition and consequent cheapness with which it reels. A mere child, whose services may be had for six cents per day, can easily turn it. The cost of a machine we understood was twelve dollars.

Extraordinary Crop of Field Peas.

On the 29th of April last, I sowed four acres of the short pod English pea, on ground that was used for corn two years previous. The ground was not manured.

The ground was plowed once, and harrowed twice. The soil was black and mucky. The quantity of seed sown on the acre, was three bushels. In August they were harvested. I threshed and measured the quantity grown on one acre, which was an average of the whole, and found they measured 88 bushels, of an excellent quality.

DAVID WASSON.

Leicester, Lin. Co., Oct. 4, 1842.

SOUTH BREVICK, ME.

Oct. 13, 1842.

MR. H. COLMAN, Sir:—There has recently come into my possession an old account book, in which I find the weight of cattle, slaughtered, Nov. 1790—nearly 50 years since. I will give you an abstract, that you may publish it in your paper, if you see fit, in contrast with the weight of a cow and heifer, slaughtered in December last, belonging to Hon. Charles N. Cogswell.

HATCH ON.	PERKINS ON.	HUSSEY COW.

The slaughtered heifer was about twenty months old.

Your Friend,

CHAS. E. NORTON.

For the New Genesee Farmer.

Mowing Land—an Experiment.

MR. H. COLMAN—Dear Sir:—There is no principle better settled, or that receives more fully the assent of mankind, than the axiom, that "Experience is the best teacher of Wisdom." The most beautiful theory in philosophy, morals, politics, or agriculture, oftentimes proves, in practice, to be a mere illusion of the brain—incapable of any practical utility. As in the question proposed to the Philosopher, "If my white sheep eat so much more grass than black ones?" the profoundest scholars have often mistaken some of the most common circumstances and operations of every day life. But the theory deduced from close observation and experience, and from the actual operation of nature, can hardly be mistaken, or as the Poet very pleasantly expresses it:

"Thine every object of creation,
My furnish hints for observation;
And from the most minute and mean,
An inquiring mind can wisdom glean."

Having recently noticed the result of an experiment in farming, which, although it may be quite common in some parts, we had never tried or seen before, and which resulted quite satisfactorily to us—somewhat to our disappointment—I thought it might be useful to the numerous readers of your widely circulated and very popular paper to have an account of it.

My father is somewhat of an experimenting and observing farmer, as you have remarked in your peregrinations in our country as Agricultural Commissioner of Mass.; an office which the farming interest of the old Bay State ought to have continued and sustained. He had a piece of mowing land near his house, of loamy soil, which, having been mowed for several years, had become turf-bound, and did not produce a good crop.

The crop of grass in 1841 was not more than half a ton per acre. Soon after it was mowed, about the first of August, (1841,) he turned it over very carefully, with one of Ruggles, Nourse & Mason's best ploughs. It was then rutted, harrowed, and manured with about 20 loads to the acre of well prepared compost manure, then harrowed again—seeded down with a large quantity of clover and herds grass seed—harrowed again, and completed by rolling. The grass seed came up well, but was put back somewhat by the dryness of the weather. The winter was uncommonly destructive to clover, and most of it was killed out. In the spring, (1842,) it looked rather poorly for some time, the season being cold and dry. But in the commencement of the warm and rainy weather, it grew amazingly; and on the latter part of July, he cut, at least two tons to the acre, of clean herds grass with a mere sprinkling of clover, the clover having been mostly killed out by winter, as I said before; a quantity more than twice as much as he would have cut, had he not plowed it.

After the first crop was cut, the weather continued warm and moist, and he has just cut the second crop of at least a ton to the acre, making not less than three tons to the acre, this season.

The experiment has succeeded beyond our most sanguine expectations. We supposed we should nearly lose the grass the first season, but hoped to gain by it afterwards. But instead of that, there has been a gain the first season of more than 200 per cent. in the quantity of grass.

Hay being one of the most profitable crops we can raise in this section of the country, it is a great desideratum to be able to lay down lands to grass without being compelled to cultivate them with corn, potatoes, oats, &c., for three or four years, thus losing the crop of grass for that time. I think that on level, loamy lands, this kind of agriculture may be practiced with success and profit.

The crops generally, in these parts, are uncommonly large. The first crop of grass was about an average one. Rye was good, and corn has ripened well and is good. Oats were very large, and the second crop of grass. I have never seen so large before. The continued rains of August and the first half of Sept., have made our pastures excellent and fall feed abundant.

Notwithstanding the vetos of the Bank and Tariff Bills, a good Providence has continued to smile upon us, and our barns and granaries are full to overflowing. And now our greatest trouble is, our crops are so abundant that prices have fallen very low. Not even the final passage of the Tariff Bill, which increases the price of most things the farmer uses, but gives him not a cent more for his produce, and diminishes the foreign market for his grain, can save us from low prices when there is an abundant harvest. Verily, man is ungrateful, but God is ever good!

We are highly pleased with the "New Genesee Farmer," under the management of its new Yankee Editor. May long life, good health and abundant prosperity attend his efforts to promote the best interests of that large and most important class of our fellow citizens—the Farmers of the United States.

H. W. C.

Barnardston, Franklin Co., Mass., Oct. 1, 1842.

P. S. An experiment of irrigating land on a scale somewhat extensive is being tried in this town, which seems to promise valuable results, and of which I will give you some account hereafter if desired.

We are very much obliged to our good friend for the above account, and heartily reciprocate all his good wishes and kind regards to him and his. Like O. T., we ask for more. This is not half enough.—Ed.

Seneca County Agricultural Society.
This Society held its Show and Fair at Waterloo on the 20th and 21st inst. The occasion was respectably attended. The show of animals was small; but those of Mr. Bacon of Waterloo, Mr. Johnson of Fayette, and Mr. Sackett of Seneca Falls are among the best of the Improved Short Horns. A Short Horn bull belonging to Mr. Dunlap, we believe, of Ovid, eighteen months old was a very remarkable animal for his size; perhaps few have exceeded him, if ever he has in this respect been excelled, and in other points he was to be commended. There was another remarkably fine bull on the ground of excellent proportions. His length and depth were remarkable; his age 5 years, his color white and brown; but his owner's name not known.

The horses shown on this occasion as a whole were uncommonly fine. We counted ten in the ring, and some of them pre eminent for their beauty, especially a bay colt three years old, and a dark sorrel horse of admirable form and carriage. The horse of all work is undoubtedly the horse for the farmers of Western New York, but this is not incompatible with beauty of form and high mettle. We cannot for the sake of the improvement of the breed of horses desire to see horse racing introduced; this in general is the improvement of the horse at the serious expense of the deterioration of the man, and it costs therefore a good deal more than it comes to. But we are always regretting that the fashion of riding on horseback for men and women, the most healthy, manly and beautiful of all forms of exercise, should be almost entirely superseded by the fashion of riding in carriages, and especially in what are usually called Carry-alls, significantly denominated by a humorous friend of ours, Kill-creatures, where a man at the expense of his poor horse feels bound to take in his wife and his wife's maiden sisters and perhaps a neighbor's wife and all his children though his family should be as numerous as that of John Rogers, the martyr in the primer, consisting of nine small children and one at the breast, which leaves the question somewhat unsettled whether there were nine or ten. This abuse of these dumb creatures is fatal to all improvement of the breed; but the fashion of riding on horseback and treating our horses better, and grooming them better, for sure most of them are scarcely groomed at all, would essentially promote the improvement of the race. Whether this is to be expected or hoped for we shall not venture to predict.

The cruelty with which this noble race of animals is often treated is most shocking. Any one, who will look at the galls and wounds upon many of our stage-horses and our canal horses will see reason to wish, that if any thing can be effected in that way, an association for the suppression of cruelty is as important as for almost any other object of moral reform. We have recently witnessed cases of cruelty in which we feel that we did great dishonor to the poor beasts in speaking of brutality as a term of approbrium for man-analy infinitely transcended it in odiousness; and we could only desire as a just retribution, that the poor, oppressed, abused and mangled animals might lay their hoofs upon the breasts or heads of their persecutors so gently as not quite to take life, for we should be sorry to have these wretches put out of misery at once, but to come so near to it that they might be at no loss to understand what blows and bruises mean, whether applied to horse flesh or man flesh. These instances show how little man is to be trusted in any case with absolute power, and what a curse would come upon the world if man could ever approximate what they so constantly desire, that is, independence, and any man were permitted to do as he pleased. The world could hardly contain such a monster as he

would be likely to become, as we see in the case of the despotic Roman Emperor, who wished that all men had but one neck that he might cut off the head of all at a single blow.

There were shown at the Fair at Waterloo, some draining tile made of clay and well baked—about 14 inches in length, 4 in width, and perhaps 5 in depth—forming half a circular tube with the sides somewhat extended. They were made by Benj. F. Whartnaby of Waterloo, and could be afforded at 30 cts. per rod. This would be a cheap mode of draining. It is generally thought only necessary, after the drain is dug, to lay them on the ground where the subsoil is hard. This we believe is an error. It has been found so in England, and many drains laid in this way it has been found necessary to take up; the water passing under the tile has softened the bed and the tile has gradually sunk down until the water course became filled up. It may cost more at first, but we should recommend in all cases laying a flat tile at the bottom to receive the circular tile. These flat tile would cost but little and a drain thus laid would last for ages. The introduction of a thorough system of draining promises the greatest improvement that our husbandry has yet seen and is destined to quadruple our crops.

From the excellent farm of Richard P. Hunt, we saw specimens of mangel wurtzel, ruta baga and especially the white carrot, which certainly spoke at the top of their voice in behalf of the excellence of the soil and the skill of the cultivator. We pronounced them at once of the mammoth variety, for no other name would suit them.

Some farmers' wives and daughters were there with very fine specimens of their handy work, and themselves very fair specimens of even a finer workmanship than their own. Some needle work wrought at the paragon was beautiful; there were handsome specimens of silk, hosiery, flannels, &c. There was a specimen of flax, perfectly cleaned of the hull by first being steamed and then passed through a machine for the purpose, which is likely to prove a great improvement over the old system of rotting and batchelling.

There were likewise exhibited some beautiful pieces of broadcloth manufactured by the Waterloo Woolen Co. of an excellent quality; and not the least interesting circumstance of this part of the exhibition, was the polite desire of the company that we should choose for ourselves a suit from their best fabrics. We gratefully and respectfully acknowledge this substantial civility; and shall wear it with pride and pleasure. Our only fear is that it may so much stimulate our self-esteem, so intimately associated with the love of country, that our hat may not be quite safe on our head in a high wind.

If the show of quadrupeds on this occasion was limited, the show of bipeds was numerous and respectable. The farmers held an agricultural meeting in the evening at the Court House between the days of the Fair. Judge Sackett, the public spirited President of the Society, presided. Several farmers poured out the rich treasures of their experience, and the evening passed off in a most instructive and delightful manner. Such meetings should be multiplied. They should always be connected with the Fairs; and might be rendered not the least attractive nor the least useful part of the occasion.

Waterloo every where indicates a rapid and healthy growth. Its Academy on the green promises to furnish the ample means of a finished education to a large number of both sexes. The building itself is well worth a visit. It displays great architectural taste and elegance, united with all the conveniences in a compendious form, desirable in such an

establishment. Let the Farmers not forget that education, substantial education, is an object which cannot interest them too much and towards which they cannot be too liberal, as the great and in truth the only instrument, next to good morals, of elevating and improving their profession and condition.

Oneida County Agricultural Society Show and Fair.

The Rome Sentinel gives a brilliant account of this occasion held at Rome on October 12th and 13th. It seems to have gone off with great eclat. "The Church," it is said, "was crowded to overflowing with one of the most intelligent assemblies of farmers, their wives and daughters, and other citizens, we have ever witnessed on similar occasions." An address was delivered by B. F. Johnson of the Central Farmer, which we can have no doubt was worthy of the occasion.

The ploughing match was attended by 2000 spectators, and as it should be, by ladies and gentlemen; for what more beautiful, innocent, and exciting pleasure, than a fair field and a spirited competition, where no cruelty is permitted and the whole tendency is the improvement of the best of all arts. Seventeen competitors entered the field.

It seems by the votes passed to have been an extraordinarily thankful occasion; and night, we should think, answer for the General Annual Thanksgiving for the year, if our good Governor does not appoint any other; for they, it seems, besides thanking the orator passed special resolutions of thanks.

To the Hon. President of the Society.

To the Corresponding Secretary, the Recording Secretary, and the Treasurer.

To the Chairman of the Committee of Arrangements.

To the young gentlemen, "who acted as Clerks and rendered such valuable aid during the Fair;" and we have no doubt to the Fair likewise, for which we presume the ladies thanked them.

To the keepers of public houses, in the village of Rome.

To the Vernon Band for their attendance.

To the Trustees of the First Church, for the use of their house.

This was certainly doing the thing up in handsome style; and will make the Society welcome, whenever its anniversary comes round.

The number in attendance was estimated at 10,000; and we now vote ten thousand thanks, that is a thank ye, to each of these good men and women, who thus encourage the best of all pursuits for comfort, happiness, and morals; and thus, by their presence and acclamation, "speed the plough."

We cannot give the premiums on animals—but we note some on crops.

Premiums were given on Winter Wheat, for 241-2 bush. per acre.

On Spring Wheat, for 311-4 bush. and 27 bush. per acre.

On Indian Corn, for 94, 91, 85, 83, 78, 71, bush. per acre. These crops are highly creditable.

On Oats; 1121-2, 94, 86, 79, bush. per acre. These crops are excellent.

On Barley; 64 53 1-4, 453-4, bush. per acre. The first crop is unusual.

On Rye; 33 bush. per acre; certainly a good crop.
On Potatoes; 435, 151 bush. per acre; rated at 60 lbs. per bushel. In giving a premium in these cases, we see the Committee decided upon the principle adopted by a clerical friend of ours in respect to his congregation, which was very sparse;—"What," said he, "they want in number, they make up in character."

On Potatoes for quantity per acre, entries were made for 693, 432, 396, 372, 368, 360, 337, 232 bushels.

We see no Robans among the number; so transient is popularity among potatoes as well as all other earthy things. We believe, however, they were represented afterwards; and also potatoes called "Perfectionists"; of Mormons, none appeared; they belong, we believe to a side-hill in Ontario county.

On one crop of Ruta Baga, of one quarter of an acre, at the rate of 284 bushels per acre. To give a premium on such a crop as this would, we should fear, disturb poor Cobbett's bones in his grave.

On Sugar Beets, 379 bushels. On Mangel Wortzel, 115 bushels.

On Carrots, 554 bushels per acre. We have grown a thousand bushels, and we have known crops at the rate of 1390 and 1780 bushels per acre. Premiums were given on silk, flannel, and Sugar all of which were pronounced excellent. Sugar always finds favor. This Committee are always a tasting Committee; and we defy a man to say an unkind thing with a large lump of sugar under his cheek. We have never yet seen the woman that could scold her husband with a piece of double refined loaf sugar in her mouth, and we recommend it as a preventive.

Various other articles were honored; but alas! a pair of white German Geese were overlooked. Strange they had not asserted their rights among other pairs of geese, which possibly may have been there. The Romans! the Romans! of all people in the world to overlook the geese. Base ingratitude! The old Romans never forgot the descendants of their distinguished benefactors, who saved the Capitol. They made the Goose the object of their idolatry. Sad degeneracy among these modern Romans!

A premium was awarded to a lady for a pair of embroidered Ottomans, for which 80 dollars were offered. This illustrates the hardness of the times. The lady, we would remind the young men, is single from her name; and a pair of ottomans seems to imply a spare seat for somebody.

A premium was awarded for a very superior bed-quilt to a lady, the maker of it, with but one arm. So fertile is human ingenuity in meeting emergencies and rising above difficulties.

Last of all, a premium for a *Climax* Cooking Stove. This must be a curiosity. We can imagine nothing farther than has been already accomplished; but this we presume not only cooks the dinner but serves it up at the same operation.

The occasion seems to have been most auspicious.

To Correspondents.

We have a valuable and valued communication from Flora for our next number. J. T. Y. will find his wishes, in which we cordially join him, in this matter anticipated. We hope to hear from him again and often. Our friend Horsefield's communication on Mediterranean Wheat will appear in our next. We do not much differ in opinion.

We thank our friend J. K. of Portsmouth, for his letter on the different breeds of Poultry.

"The cock with crow
To let you know
What time to rise."

Right glad are we that his crowing has waked our friend up, from whom we should be glad to hear often.

Communications from W. G. and W. B., on the Protection Policy, designed for this number, together with many other articles are necessarily excluded for the present, as well as several accounts of cattle shows in this State, and New England. We are pained to say to our respected Correspondent, J. S. D., that it was intended to have inserted two more of his letters in the present number; but our compositor being suddenly called away a distance of 500 miles by the death of his father put them where they could not be found by the most diligent search.

Several communications from J. D., E. H. S., and others, are on hand for future use.

Fruit Trees.

It is a common practice with the farmers of this section to set out fruit trees on old land, and seed it with timothy or clover seed. In a few years the trees become stunted and have rough mossy bark and yellow leaves, showing every sign of starvation. In this way thousands of young fruit trees become worthless to their owners and useless to the soil. This is probably owing to the hardness of the soil, not being plowed often, and to the encroachment of the roots of the grass on the roots of the trees, so that in a few years the roots of the grass become matted around the trees. Farmers who have such orchards should immediately plow them up; and if practicable set out new trees. If not, clear the grass away from the trees and put well rotted chip manure around them or leaves gathered from the forest will answer the same purpose.

Fruit trees, especially those which are young, should be hoed or plowed around at least once a month during the spring and summer. I know of no reason why the sub-soil plow would not do well for land that is intended for orchards. It would certainly save labor in setting out trees in a hard or clayey soil.

II.

Our correspondent H., wishes some information in regard to the use of ashes. He will find a highly interesting communication on that subject, in the paper of this month, translated from the German for the New Genesee Farmer. We know not where to commend him to any thing more instructive. We publish his suggestions in regard to fruit trees that we may bring the subject to the attention of the farmers, not that they present any thing new in relation to the subject. Fruit trees need as much and as careful cultivation as any plants which grow out of the ground. There can be no question that the use of the sub-soil plow, together with every other method by which the soil can be broken, or kept loose, would be beneficial.—Ed.

We publish below from the Seneca Falls Democrat an account of a Stove invented by E. Foote, Jr., of that place. We subjoin likewise a letter from a gentleman at whose house we saw the Stove in operation. We believe from what we saw, that it is a highly valuable improvement, both as it respects economy and comfort. It is now a days with stoves, both cooking and parlor stoves, as it is with ladies' bonnets. The man, who purchases one of the latter must hurry home, or the fashion may change, before it can be mounted. Such rapid changes are constantly taking place in all kinds of heating apparatus, that it is very difficult to keep pace with them, and a man feels hardly safe in buying one with certificates to its efficacy as numerous and long as the joints in the funnel. A friend of ours declared he would not buy a cooking stove until "they had done making improvements," but as the hymn says, "he died without the sight." We believe Mr. Foote's Stove an excellent machine and answering its purpose well. We cannot say that better will not be invented. We know that many worse have been. What Mr. Davison means by burning a cord of wood a week in a Franklin Stove we do not well understand, unless he was engaged in clearing land, or trying to heat the large room outside of his house, and help Professor Espy in some of his philosophical experiments—otherwise he ought to be indicted for extravagance; and we are quite certain he has never had the luxury we have had of paying eight dollars a cord for wood besides the sawing.—Ed.

SELF-REGULATING STOVE—INVENTED

BY E. FOOTE, JR., OF SENECA FALLS.

A remarkable property possessed by this Stove, is that of governing its own heat, so as to maintain, without variation, the precise degree which may be

required. Within and near the upper part of the Stove, is placed a brass rod—straight and inflexible. Should the heat rise too high, the expansion of the rod, acting on a lever by which its motion is much increased, is made to elase a damper that governs the admission of air.—Or should the heat fall too low, the contraction of the rod opens the damper and lets in a full draft. A sufficient quantity of fuel being placed in the stove, its burning is held in constant check by the closing of the damper—consuming no faster than a want of sufficient heat to keep it closed permits. Thus is kept an uniform heat.

The manner in which the degree of heat at which the stove shall maintain itself, is changed, is equally simple, though not so easily described: By merely moving a pointer, different degrees of expansion, and of course different degrees of heat, are required to close or to open the damper. A dial plate, like the face of a clock, forms a part of the front of the stove. On this are marked the different degrees of heat required—and the index being turned to a degree, the stove will immediately adapt itself to that point, and there remain without variation.

And the invention stopped here, there would have been left a defect which probably would have destroyed its usefulness. Should the heat rise so high as to close the damper, and then from any cause continue to rise above that point, some part of the structure must necessarily give way, or else be so loosely and imperfectly made as to allow such variation.—Or should the heat continue to fall after opening the damper, the same difficulty would be presented. We regret that we cannot, without drawings, convey to the reader the manner in which these difficulties are removed. The moment the heat should rise above the point of closing the damper, the rod disconnects and detaches itself from it, and so remains until the heat returns again to the same point—when immediately it re-connects itself, and resumes its appropriate duties: Or should the heat fall after opening the damper, the rod becomes disconnected until a return to the same point. This part, more than any other, will strike the attention of the machine. It is said to be before unknown in mechanics, and is as remarkable for its simplicity as its ingenuity.

The stove has various other valuable qualities. It is estimated that from three-fourths to five-sixths of the heat from the fuel consumed in an ordinary stove, is carried off by the current passing through it to the chimney. In this stove, no more air being admitted than is necessary to sustain the combustion, very little current is made, and nearly all the heat is expended in the room. And besides, the smoke and cinders, being long retained in contact with the fire, are mostly consumed. The fuel in this stove being permitted to burn no faster than is wanted—enough may be put in at once to last 12 or 24 hours. Wood is converted into a bed of charcoal, which gradually consumes, but no faster than is required. A person may go from home, and leave his stove through the day, or through the night, and when he returns find it at precisely the same temperature at which he left it.

SENECA FALLS, JUNE 24, 1842.

DEAR SIR:—I send you herewith one of our village newspapers, containing as full an account of the mode of operation of Mr. Foote's Self-Regulating Stove as I could give you.

When in Seneca Falls, you saw the room in which I used the stove; it is 18 by 20 feet square. My house is not a warm one; it is built of wood, and admits considerable air. Previous to getting this Self-Regulator, I used a common Franklin. In this the consumption of wood was near as I can remember, was one cord per week during the four colder months. I have made a number of experiments with the Self-Regulator in the same place, and have uniformly found that one solid foot of good wood was an abundance to keep a thermometer in my room at 70 degrees, 24 hours that amount per day, (incredible as it may seem,) I think would be a full allowance for the whole winter. The pleasantness of an uniform temperature and the great saving in attendance upon fires, are also important requisites. In the latter item alone I have saved enough to repay me the price of the stove three or four times in the past winter.

Respectfully yours,

W. T. DAVISON.

Magazine of Horticulture for September.

We cordially commend to our readers this valuable publication, edited by C. M. Hovey and published monthly in Boston. We should be very happy to forward names or subscriptions for a work which deserves the patronage of the friends of Gardening, Fruits and Flowers in the country. We extract from this number an interesting and useful article on the currant.

Remarks on the Cultivation of the Currant.

Very few of our garden fruits are so much neglected as the currant. Its cultivation seems to be a matter of no consideration, and when the bushes are once planted, they are left to take their chance, and little attention is bestowed upon them afterwards. Pruning is entirely forgotten, and the plants often become a prey to insects, which soon destroy them. A fruit so generally admired for its good qualities and its many excellent uses, and so universally cultivated that scarcely a garden exists in which it may not be found, should not be so entirely neglected; for, like all other fruits and plants, it is susceptible of improvement, and had the same attention been given to it that has been lavished upon the gooseberry, we doubt not but that new varieties, far exceeding any we now possess, would have been found in our gardens, as common as the new and improved sorts of that fruit.

In France the currant has long attracted attention, not, unfortunately, and more highly esteemed than the gooseberry. But the French horticulturists did not attempt any improvement in the varieties. The Dutch cultivators were the first who seem to have paid particular attention to it; they succeeded in giving a greater value to this fruit by the production of seedlings, and it is from this source that the very best varieties at present known have been spread over Europe and America.

The late Thomas Andrew Knight, Esq., President of the London Horticultural Society, called the attention of cultivators to the currant, and he attempted the production of new varieties from seed. The currant, he thought, might eventually become a very sweet fruit.

It is well known that the accidental circumstances of soil, situation, &c., in which the currant has been grown, have been the means of so altering the appearance and character of the fruit, that new names have been given to such as have been found in a superior state of growth, and some of the sorts are known and sold as half a dozen synonymous terms. We have known only those who have cultivated the currant many years, who upon seeing this sort of superlative growth, have inquired the name of the variety, under the impression that they might add a larger and better sort to their garden; yet how surprised have they been to learn that it was one and the same kind of which they had abundance already, only in a smaller and neglected state of growth. It is indeed a rare circumstance to find plants in any thing like the vigor they can be made to attain by proper cultivation, the neglect of manure, and above all, the proper mode of pruning.

Within a few years some attempts have been made to produce new seedlings, and we find in the English journals of the present year, two or three new varieties offered for sale. Among our own cultivators, very few have thought of bestowing so much care on this fruit; yet there are instances where it has been done, and with good success. Captain Lovett, of Blythe, presented some very beautiful fruit at a late meeting of the Massachusetts Horticultural Society, which would not suffer in comparison with the celebrated Red Dutch; the clusters of fruit were large, and the berries of great size and fine color; continued experiments, however, are requisite to arrive at important results, and effect double improvement; by continually selecting the largest fruit, and producing successive generations, in a few years the whole character of the fruit would undoubtedly be much changed. In the gooseberry, fruit, from a small, sour, and almost unpalatable fruit, has been increased to three times its original size, its flavor and sweetness improved, why give not the currant, by the same attention, the equally beneficial, and rendered more worthy of extensive cultivation? We hope our amateur horticulturists, among whom are many who delight in the production of improved fruits, will not omit to give the currant a portion of their attention.

But it is to the cultivation of the well known and excellent varieties of the currant which we already possess that we wish to call the attention of cultivators. If their mode of treatment be properly understood, it may be applied to any improved varieties, which may hereafter take the place of those that are

now known. To give this in full, we shall commence with the Production of Seedlings, and add all the other particulars of their growth under the following heads:—Situation, Soil, Raising Young Plants, Planting Out, Pruning, (both summer and winter,) Insects, and General Observations, concluding with Description of the Different Varieties.

Raising the Currant from Seed.—To grow seedlings, it is important that the largest and best fruit should be selected. To do this, a strong and healthy plant should be selected, and if too full of fruit to permit its attaining a good size, it should be thinned out, leaving only sufficient for the plant to bring to the utmost perfection; as soon as the fruit is ripe, it should be picked, and the seeds washed out from the pulp; this may be easily done by bruising the seeds in water, and passing the whole through a sieve, and afterwards spreading it out in a cool, shady situation to dry, after which it may be placed in papers until the time of planting in the month of April. At that season a small piece of ground should be selected for the purpose, and be made fine by deep spading and raking the surface; the seed may then be planted in drills about a foot apart, scattering it thinly that the plants may not come up so crowded as to require thinning out by any extent. No other care is requisite than to keep the land clear of weeds; they will produce fruit in the second or third year, when such as are worth preserving should be marked, and the remainder rooted up and thrown away.

Situation.—The currant is perfectly hardy, and will grow in any situation, whether exposed or not; but it produces the largest and best fruit in a sheltered garden, not exposed to high winds. In warm and sunny borders, the fruit is ripe earlier, and is somewhat green, then when growing in partially shady situations; against a north wall, the fruit will hang on the bushes until the middle or latter part of September. Even within the shade of trees we have found very fine fruit; but we would not select such a spot to raise the best. Besides a few bushes set out for the express purpose of having fine fruit, the currant may be distinguished in any part of the garden where a bush will fill up a vacant spot; they may also be trained against fences, in which situations they bear good crops.

Soil.—The currant will grow in almost any good garden soil; but that in which they produce the best fruit is the greatest perfection is deep, rich, mellow loam, somewhat moist; very stiff clayey soils are the least adapted to it. In sandy soils the fruit is earlier, but the crop is small, and soon gone. When it is the object to produce a very superior fruit, the soil should be soaked out, and then covered with three or four inches of good old decomposed manure. It should then be trenched eighteen or twenty inches deep, placing the top soil and the manure at the bottom of the trench. When the bed is settled, a little manure may be dug into the surface, and it will then be ready for planting.

Raising Young Plants.—Cultivators who wish to make large plantations, and are desirous of raising their own plants, can easily do so. The cuttings should be planted out in April, just as the buds begin to push, selecting a shady border, and planting them five or six inches apart; the cuttings should be about a foot long, of the preceding year's wood, healthy and vigorous, and cut off directly below a joint. If the bushes are to be grown in a manner of small ones, with one main stem, all the eyes should be cut out but the two top ones. Planted out in this manner, they make pretty plants, which may be removed to the fruiting bed the following year.

Planting Out.—The period for planting out is any time after the fall of the leaf in autumn until severe frost, and early in spring before the buds have passed to far as to show their river buds. In dry situations, October is probably the favorable season as can be selected, as the plants start into leaf very early in the spring, often before the cultivator thinks it time to plant out, and a season is lost; but if the ground is inclined to be wet in winter, the early part of April is the best season. The modes of planting are various, some preferring to place them on the borders of walks, and others in belts by themselves; we think the best plan is to place the trees in rows, to set apart a wide piece of ground for their exclusive growth; but whatever situation is chosen, prepare the soils as above directed. The proper distance at which plants should be planted, is six feet apart between the rows, and four feet from plant to plant; less distances than these will do, but the chances of producing large fruit will be less. To plant neatly, a line should be stretched across the bed; at the proper distances put down a small stake, then commence taking out the earth; now place in the plant, setting

against the line; spread out the roots carefully, and cover them with fine earth, making it firm around the roots, and treading it lightly when finished; give each plant a pot of water, if dry weather at the time of planting. Keep the surface of the soil loose, and clear from weeds, by occasional hoeings during the summer.

Pruning.—Nest to a good rich soil, pruning is the most important thing to be attended to; neglect in this respect will be sure to cause disappointment to the cultivator who expects large and fine fruit. The branches will shoot up thick and weakly, and if not attended to, and the superfluous ones cut out, the bush will be so crowded as to produce only a quantity of half formed clusters, with a few small berries.

It is known to many cultivators, though perhaps not to all, that the currant bears its fruit both upon the young wood of last year's growth, upon that of the second and third year, and also upon the little spurs which spring from the older shoots; but it is only upon the young and vigorous wood of the preceding year that fruit of superior size and quality is obtained. Knowing this fact, the cultivator may proceed with his pruning, which may be done at two seasons, both winter and summer, viz:—

Winter Pruning.—The first object should be, after the plant is set out, to see that it is pruned as to form a handsome head; and, first, we may premise that it is the intention to prune them in the best method, that is, with single stems, like trees in miniature, from which the branches fork out at the distance of a foot or more from the ground; this will prevent the continual growth of suckers, which not only injure the fruit, springing up as they do the whole season, but destroy the beauty and regularity of a whole plantation. Winter pruning may be performed late in the autumn, or early in the spring; as the currant is extremely brittle shoots, some think it best to prune in the fall, and by this shortening the branches, to bring the danger of the heavy snows breaking them down.

Commenced by cutting clean out all the cross shoots, leaving only those which spring up regularly. The strongest branches of the old wood should be shortened to six or eight inches, and the weaker ones to very short spurs; the new wood made during the summer should be also shortened to four or five buds or joints. The principle ever to be kept in mind is, to have the head of the bush supplied in all parts with a good proportion of new wood every season; and this can only be done by cutting away the older branches after they have borne one or two crops, and encouraging the growth of young shoots from their base; at no time should the head of the bush be allowed to extend more than three feet in diameter, and three feet high.

Summer Pruning.—This consists only in looking over the plants, after the fruit is well formed, and nipping off new shoots which are growing up where they are not wanted another year; by so doing, an abundance of or will be admitted to the centre of the bush, without which the fruit would be inferior. Some cultivators recommend shortening the bearing branches to within a few eyes of the fruit, as soon as it turns color, but of the advantage to be derived from this practice we have some doubt. If any suckers spring from the root, they should be cut off clean to the stem.

Insects.—The currant has few enemies in the insect tribe; the most injurious is the borer, (*Agria tipuliformis*), which enters up to the centre of the stems, causing great debility, and eventually nearly destroying the plants, or at least incapacitating them from producing any thing but very small and poor fruit; the bushes are also in danger of being injured by light winds or with heavy crops of fruit. The best preventive for this insect is to keep the plants in a vigorous state, and well supplied with strong young wood, as it is only in the older branches that the borer commences its ravages. When they once take possession of the bushes, cut out all the old shoots, especially such as are in any way decayed, and encourage only strong new wood; the aphides, or plant lice, occasionally infest the leaves, but these may be easily destroyed by one or two washings of weak soap.

General Observations.—The French cultivators recommend the transplanting of new plantations every five years, in proportion that, unless this is attended to, the fruit will be small. We have no doubt that the fruit would be somewhat improved by such new plantations, but still, if the old bushes are judiciously pruned, the soil kept well manured and tilled, the fruit will be little necessary of planting out so often.

The fruit generally begins to ripen about the middle of July, and continues in perfection until the middle of August, and in some shady situations as late as

October. If the bushes are exposed to birds, they may be protected by covering them with nets or gauze.

We close this article with descriptions of the most esteemed varieties that are at present cultivated, following the arrangement in the London Horticultural Society's Catalogue. The Red Dutch, White Dutch, and Black Naples may be recommended for small gardens, where there is but little space.

DESCRIPTIONS OF THE DIFFERENT VARIETIES.

§ I. RED CURRENT.

1. *Common Red*.—Fruit medium size, clusters rather small, good flavored, and tolerable bearers.

2. *Red Dutch*.—*Synonymus*: Large Red Dutch, New Red Dutch, Large Red, Large-bunch Red, Long-branched Red, Morgan's Red, and Red Grape.—Cluster long, berries large, growth of the plant strong and upright; Exceedingly productive, and one of the very best sorts.

3. *Knight's Sweet Red*.—Said to be a very fine kind.

4. *Knight's Early Red*.—Rather early; clusters and berries medium size; color deep red; flavor rich and good. We fruited this variety the present year.

5. *Knight's Large Late Red*.—With very large berries, of a deep red color; superior kind.

6. *Champagne*.—Berries of a very pale red; clusters medium size; this fruit is rather acid, but makes a very good vinegar for the table, from its delicate color and transparent appearance of the berries.

§ II. WHITE CURRENT.

7. *Common White*.—The old kind of our gardens; clusters and berries medium size.

8. *White Dutch*.—*Synonymus*: New White Dutch, Jewes' White, Morgan's White, White Christal, White Leghorn; Pearl White.—This is the finest of the white currents; the clusters are very long, and the berries very large. The wood grows upright and strong; exceedingly productive and fine.

§ III. BLACK CURRENT.

9. *Black Naples*.—Also called the New Black; the fruit is very large, often two inches in circumference; clusters large, and abundantly produced; flavor good. This is the best of the black fruited ones. Leaves smooth.

10. *Common Black English*.—This is a very good variety, with large berries; it makes a fine jelly, which is highly esteemed for its medicinal qualities.

11. *American Black*.—Similar to the last, but is not quite so productive.

Knowledge is Power.

In a late admirable report by Horner Mann, Esq., Secretary of the Board of Education of Massachusetts, the following striking exemplification is introduced of the maxim that "knowledge is power."

"M. Redelet, in his work, '*Sur l'Art de Btir*,' gives the following account of an experiment made to test the different amounts of force which, under different circumstances, were necessary to move a block of squared granite weighing 1,080 lbs.

"In order to move this block along the floor of a roughly chiselled quarry, it required a force equal to 753 lbs.

"To draw the same stone over a floor of planks, it required a force equal to 652 lbs.

"Placed on a platform of wood, the requisite force was reduced to 183 lbs.

"Placed on rollers of three inches in diameter, and a force equal to 34 lbs. was sufficient

"Substituting a wooden floor at the floor, and the requisite force was 28 lbs.

"With the same rollers on a wooden platform, it required a force equal to 22 lbs. only.

"At this point," says Mr. Mann, "the experiments of M. Redelet stopped. But, by improvements since effected, in the invention and use of locomotives on railroads, attraction or draft of eight pounds is sufficient to move a ton of 2,240 lbs.; so that a force of less than four pounds would now be sufficient to move the granite block of 1,080 lbs., that is, one hundred and eighty-eight times less than was required in the first instance. When, therefore, mere animal or muscular force was used to move the body, it required about two thirds of its own weight to accomplish the object; but, by adding the contrivances of mind to the strength of muscle, the force necessary to move it is reduced more than one hundred and eighty-eight times. Here, then, is a partnership, in which mind contributes one hundred and eighty-eight shares of the stock to one share contributed by muscle; or while brute strength represents one man, ingenuity or intelligence represents one hundred and eighty-eight men.—*Nat. Int.*

The following statement makes a part of the Lecture of James Smith of Danston, on Subsoil Ploughing and Draining. It may surprise many of our farmers to learn the expenses of cultivation in Great Britain; and we think it will not surprise them less to see the results of such cultivation. The extraordinary profits of the New Husbandry compared with the old system are astonishing; and exhibit the beneficial and liberal compensations of science, skill, judicious expenditure and well directed labor. They should serve to electricity some of our farmers, who are satisfied with a crop of twenty bushels of wheat and forty of Indian Corn, and other crops on the same scale.—*Ed.*

I have received from a landed proprietor and practical farmer in Avonshire, the following statement of the results which have attended the practice of thorough draining and subsoil ploughing, according to this system:—

IMPROVED MODERN HUSBANDRY COMPARED WITH THE OLD SYSTEM.

The following important facts have been communicated to the Directors of the General Agricultural Association by a very experienced practical agriculturist:—

I.—OLD SYSTEM.

Statement showing the expense of cultivation of, together with the return from, an acre (Scotch) of cold, stiff soil, with a hard retentive subsoil, before improvement by draining, &c.; lease for 18 years; rent, 25s per acre.

60 bulls lime, at 10s. per boll.....	£2 10 0
Cutting and spreading.....	1 10 0
Fosterer—ploughing, seed, and harrowing.....	1 18 0
Second do.....	1 15 0
Grass seeds and harrowing.....	0 10 0
Rent for six years, at 25s.....	7 10 0
	£15 13 0

Return of a Six Year's Rotation.

1st—5 quarters oats (with straw).....	£6 0 0
2d—5 do.....	6 0 0
3d—85 stones hay, at 3s. per 100 stones.....	2 11 0
4th—Pasture, at 20s.....	1 0 0
5th—Ditto.....	1 0 0
6th—Ditto.....	1 0 0
	£17 11 0

The same repeated till the end of the lease, the land getting worse instead of improving.

II.—NEW SYSTEM.

Statement showing the expense of improvement, cultivation, and return from an acre of the same land, during a lease of 18 years; rent the same.

Expense of the first Six Years.

Draining with tiles at 15 ft. interval, 25 in deep; tiles 21s. per thousand.....	£7 0 0
Lime, cutting and spreading.....	4 0 0
Ploughing, harrowing and seed.....	1 18 0
Second crop—ploughing, harrowing, and seed.....	1 16 0
	£14 14 0

Expense of Green Crop, viz.

Sub-soil and other ploughings.....	£4 0 0
Grubbing, horse hoeing, and weeding.....	1 10 0
Dang, 10s; lime, 12s.....	11 5 0
Ploughing for wheat and seed.....	2 6 0
Grass seeds, harrowing and rolling.....	1 5 0
Rent for six years, at 25s.....	7 10 0
Interest on expense for draining for five years, at 5 per cent. per annum.....	1 15 0
	£44 5 0

Return of the first Six Years.

1st—8 quarters oats (with straw).....	£10 0 0
2d—8 do.....	10 0 0
3d—Potatoes 3; turnips, 3, at per acre.....	11 0 0
4th—4 quarters wheat, at 60s.....	12 0 0
5th—150 stones hay, at 3s.; faggots 5s.....	4 15 0
6th—Pasture, at per acre.....	2 0 0
	£49 15 0

Expense of the second Six Years.

1st—Ploughing, harrowing, and seed.....	£ 3 12 0
2nd—do do.....	1 10 0
3rd—Green crop, without subsoil ploughing.....	13 0 0

4th—Ploughing for wheat and seed.....	2 4 0
5th—Grass seeds, harrowing, and rolling.....	1 5 0
Rent for six years, at 25.....	7 10 0
Interest on draining, six years.....	2 2 0
	£28 3 0

Return for the second Six Years

1st—9 quarters oats (with straw).....	£11 5 0
2nd—9 do.....	11 5 0
3rd—Green crop—at least.....	12 0 0
4th—5 quarters wheat, at 60s.....	15 0 0
5th—200 stones hay, at 3s.; faggots, 5s.....	6 5 0
6th—Pasture, at per acre.....	2 0 0
	£57 15 0

The expense and return of the third six years will be much the same as that of the second.

ABSTRACT.

1.—Unimproved Lands.

Expense during a lease of 18 years.....	£46 19 0
Return do.....	52 13 0

Profit per acre during the whole lease.....£ 5 14 0

II.—Improved Land.

Expense of the first six years.....	41 5 0
do second do.....	28 3 0
do third do.....	28 3 0
	£139 11 0

Return of the first six years.....	49 15 0
do second do.....	57 15 0
do third do.....	57 15 0
	£165 5 0

Profit per acre during the whole lease.....£ 64 14 0

The above system of cropping is not one to be generally recommended: it is merely adopted because generally followed. If the four or five course rotation were adopted, the profit per acre during the lease would be considerably above the sum mentioned.

Inquiries in reference to Daniels' Manure, and likewise Gypsum—addressed to the Royal Agricultural Society.

Mr. T. Smith, Secretary of the Board of Agriculture of Nova Scotia observes in reference to Daniel's manure.

"It is the new Patent Manure composed of pulverized wood saturated with bituminous matter, united with soda and lime, of more value than the lime and soda used without the other articles? Soda is certainly a powerful manure, but too expensive. We have in Nova Scotia large tracts in which the soil contains so much iron vitriol, (that is green copper)—rust of iron united to oil of vitriol, chemically termed sulphuric acid) that lime in such quantities as are commonly used, has no sensible effect; but on such soils, oyster shells, coral, gravel, or old plaster, have a permanent good effect, owing probably to the quantity of carbonic acid gas which is disengaged from the calcareous or chalky substances by the action upon them of the vitriol or sulphuric acid which is constantly forming from the decaying pyrites, or sulphuret of iron in the subjacent rock. Wood ashes, even after "leaching" by the soap boilers, make a permanent and powerful manure: they contain here a large quantity of sulphate of potash. It is observable, that at a great distance from the sea, ashes are of less value, while gypsum, which has no effect near the sea, is on many crops very useful in inland situations. It may also be observed, that very high winds here sometimes throw showers of salt water over the land, to the distance of twenty or five and twenty miles from the sea, the water being sometimes much saltier than the sea water when it falls. As the line that marks the situation where gypsum commences to be useful, is near that which limits these salt showers, may it not be that the salt prevents the gypsum from operating?"

THE THAMES TUNNEL.—The whole of the tunnel, nearly 1,200 feet in length, is now completed, and will be opened in a very short time as a public thoroughfare for foot passengers; the workmen are busily engaged in erecting the staircase on the Wapping side, which is all that remains to complete this extraordinary work. The machinery, steam engines, and surplus materials are advertised to be sold by auction, by Messrs. Pullen, including the powerful apparatus called "the shield," by means of which the work was accomplished. It is said to contain 150 tons of iron, and to have cost £10,000.

THE NEW GENESEE FARMER

AND GARDENER'S JOURNAL

B. BATERHAM, Proprietor. } VOL. 3. ROCHESTER, DECEMBER, 1842. NO. 12. } HENRY COLMAN, Editor.

IMPORTANT ANNOUNCEMENT!

the Farmers, the Subscribers and Friends to the New Genesee Farmer.

The world is full of changes, and in the language the old play: "we know what we are, but we do not know what we shall be." The proprietorship of this paper has now passed into the hands of C. F. Berman of the Rochester Seed Store, well known for his punctuality, uprightness, and interest in agricultural improvements, to this community, and of E. Shepard, an experienced and respectable publisher in this city, of established character. The reasons for this change will be given below, and the subscriber has a strong confidence that its good character will be fully maintained, and his hopes are as strong that its usefulness will be extended.

It will be seen from an advertisement in another part of this sheet, that he contemplates a Tour in Europe for the purpose of looking at the agriculture of the agricultural institutions and schools of the world, to ascertain what is worthy to be translated to the New. The practicability of the project was not ascertained until since the last number of the N. G. Farmer was issued. It is now determined, evidence permitting, that the subscriber leaves for Europe in the ensuing spring. It is expected, under the present arrangements, that Mr. Colman will continue to edit it for the first third of the year; and re-appear afterwards a regular contributor to its columns the close of this volume; and that when it passes into his supervision, whether it be sooner or later, it will be edited by such as are perfectly competent to make the paper all that its best friends can desire it should be. No part of that which will go into his agricultural Tour will appear in this paper, for this would be unjust to his subscribers; but there will be many other valuable topics of conversation and inquiry in which he promises himself the pleasure of setting them; as to keep the chain of friendship tight and unbroken.

He strongly hopes that their patronage will be heartily continued; and that every subscriber will exert himself to procure others, so that the list, as ought to be, may be doubled.

The price will be one dollar. It cannot be afforded for less, and remunerate or save from loss those who edit and publish it. Where twenty copies are taken, the year's subscription will not exceed twenty-five cents. What is this compared with the equivalent in useful instruction to be obtained from it? This is not two cents a week for ten pages of closely printed matter per month, but, if it were published in the common form, a good duodecimo volume. Let us look at other illustrations of the case, for when any object to paying a dollar or seventy cents for the Paper, we cannot think that they look at the matter in a fair light. A sheaf of wheat ordinarily pays for the year's subscription. Is this anything compared with the intrinsic value of a paper, which may in many cases, improve your cultivation by hundreds of dollars? Fur-

ther, I have within the last year been often struck with one fact. In going into a public house or hotel in most parts of the country, we are charged half a dollar for a single meal, breakfast, dinner or supper, and the same for lodging; so that whenever I took a meal at any such place, I was compelled to say to myself as soon as I opened my mouth, down goes one subscriber for the N. G. Farmer; and if my business or convenience required me to stay two or three days, why then I eat them by dozens, like a hungry man making a meal of small fish, or of ground sparrows or snowbirds. I was often led to reflect, does a whole year's paper come to no more than this? Look again at the case—I cannot go into my office or traverse the streets of this gaudy city without being fumigated with tobacco smoke. And without meeting continually with people who, I think, ought to be indicted under the statute as public nuisances, who go about smoking themselves and smacking others with odious segars. I dare say this may be very pleasant to them and is deemed a precious luxury; I do not wish to detract from the happiness of any man, but how infinitely higher are all pleasures connected with the mind, than this low, sensual and selfish gratification; yet the saving only of one segar a week, think of it, would give them the New Genesee Farmer a whole year even at its increased price; and more than this. Now, I have often said to myself, can it be that this is all that is asked for such a boon? Then again if really pulling is so delicious a pleasure, why let them honestly leave off smoking and become subscribers to the Farmer; and we will promise to give them such a puffing in our columns as shall do them good all the days of their lives, and be redolent with the most precious odors which taste and skill can compound; odors as different from those with which they compliment their unoffending neighbors, as the perfumes of Eden are superior to the sulphuretted hydrogen of a pig sty.

I might give other illustrations. One year's product of a good Hive of bees, which demands little more trouble than that of taking out the honey, will in many cases pay at once five years subscription to the Farmer, and this intellectual hive we promise to store with honey gathered from the flowers of every clime, as nutritious to the mind as it is delicious to the taste. Pardon me if I say further, that there is not a farmer in the country, though as poor as the whole live stock amounts only to a single pair of barn yard fowls, who demand nothing for their support but chaff and worms and grasshoppers, who will not find these humble friends, if he will only allow them to go to housekeeping and rear their family in a sober and regular way, like all respectable people, ready in all probability, to pay more than two years' subscription for the paper in a single season. What shall we think then of a farmer, who, under such circumstances, will presume to say that he is too poor to take this paper? So a single sheep, mutton headed as this amiable class of beings are, and never suspected of being the patrons of literature, excepting

as their skins may be converted into parchments for writing, or leather for the covering of books, may at once become a subscriber to this new paper; and in her wool or her lamb, will be ready to honor at sight the printer's draft.

NOW THEN IN REPLY TO A RESPECTED CORRESPONDENT AT WHEATLAND, WE HAVE POINTED OUT SIX DIFFERENT WAYS OF PAYING FOR THE N. G. FARMER.

FIRST, by one bushel of wheat taken out of your five hundred, to be charged to the account of seed sown, from which you are to reap fifty fold.

SECOND, by saving two meals at a public house in the course of the year; in which case a good deal more is often saved than the cost of the meals.

THIRD, by limiting yourself to nineteen segars instead of twenty in the course of the week, by which means likewise, there would be something saved to your health, to your good manners, to your neighbor's comfort; and to your country's reputation, if Mr. Box should come this way again. O! the Dickens, you'll say.

FOURTH, by raising a hive of Bees, whose twenty or forty pounds of honey and a swarm to sell, may pay several years subscription, besides the beautiful example of industry, which these little folks will exhibit to the other little folks of the family; and the pattern of a well ordered community, so instructive to yourself as the citizen of a republic.

FIFTH, by the suitable encouragement of one Mr. Cockerel and his spouse, who, enjoying your protection but demanding nothing from your purse, will jointly produce eggs and chickens enough in the season to make the editor crow as loud as ever one Chapman (we think that is the name, though we are no politicians) ever crowed in a log-cabin campaign.

SIXTHLY, by setting aside one sheep in your flock of hundreds, who is to be considered in the family as the patron of agricultural literature; and consequently to be treated with all the respect and kindness due to so useful a personage.

We might point out one hundred other ways on the farm in which the paper may be paid for without a consciousness of its expense; and with a hundred per cent. profit in the exertion: for there is scarcely a child five years old, in a farmer's well ordered family, who may not pay for the Farmer with a week's knitting, and with all advantage to their own education.

The publishers of the N. G. Farmer engage to present it with the commencement of the New Year, in a new and handsome dress. They promise in its preparation the best services which they can procure. The pleasure and profit which it will bring to the farmer's family and children they believe will be worth fifty times its cost. On public as well as private grounds, they hope the farmers will encourage it. The press is the most powerful engine, which can present or human ingenuity can devise, for the advancement of any good cause. What farmer, then, deserving a place in that most honorable class, will withhold his aid on any occasion from the advancement of agriculture, a cause among the most innocent and the most useful, the very foundation of human subsistence, the spring of some of the purest pleasures which the heart can take in, the guardian and promoter of good morals, the great instrument of civilization and the pioneer of religion.

HENRY COLMAN

Rochester, Dec. 14th, 1842.

Silk Culture.

The following communication we acknowledge with pleasure. Men are always willing to boast of their success, but few men are brave enough to tell of their mistakes and failures, which are often more useful and important to be known than their successful results.

In some respects we cannot agree with Mr. Cook. A prepared, finished and furnished cocoonery, well adapted to ventilation and warming at pleasure, is undoubtedly to be preferred; but within our knowledge good silk and an abundant product have been obtained in feeding in vacant barns and granaries. We recommend a well built cocoonery, believing that the cultivator will be in the end fully compensated for the expense and outlay; but at the same time we would not have poor and small cultivators prevented or discouraged in their operations, because they have not the means of at once erecting a well finished cocoonery. In Mansfield, Ct., where silk has been successfully raised for seventy years, such provision is scarcely known. That the time of feeding may by the best arrangements be reduced from six weeks to little more than three weeks is a very material consideration to recommend the best fixtures; and as by the improved French method, attention day and night, in order to the most rapid completion of the work. The disease, to which Mr. Cook refers, is a formidable obstacle in the culture of silk. We cannot say from his account of it, that it is the disease known in Europe as the *muscadine* and which it has been said confidently, may be cured by a sprinkling of caustic lime upon the worms; but we know that a friend of ours, whose worms were diseased this season and died in great numbers, applied lime as directed without any perceptible benefit. We need much more information than we have in the case before we can pronounce on the character of, or the remedy for the disease. That the worm may be injured by feeding from the leaves of the mullein of one year's growth is not improbable, as we have heard from a very intelligent silk grower the same opinion strongly expressed.

In respect to the destruction of the *Chrysalis* we would recommend Miss Rapp's method of stifling them in a box with camphor; though we know those, who do it by steam in preference to all other modes without the inconvenience or ill effects which Mr. Cook describes. They are careful however in the case not to allow the current of steam to be poured directly upon the cocoons; but the cocoons receive it as it becomes gradually diffused through the box or vessel in which they are placed.

With respect to the insect, which Mr. Cook describes as perforating the cocoons and materially injuring their value, we know at present of no certain preventive. This is a not a frequent accident. An excellent silk grower of long experience however advises that when the cocoons are put away Scotch snuff or tobacco should be put among them, as is done among woolen cloths in summer, to keep off the insects. This he thinks would prove an effectual security. It is a curious fact that there seems to be no animal, except the human, filthy enough to relish or rather not to be absolutely offended with this detestable weed; and which in the vile habits of chewing and smoking with their peculiar accompaniments renders its devotees in most cases a perfect nuisance to decent people.

We fully agree with Mr. Cook in the opinion that the silk culture can never succeed without pains-taking and care and labor. Nothing good in life can ever be accomplished without these; and with these the silk culture is almost sure to return an ample compensation for all the labor and expense incurred.—Ed.

PERRY FARM, SOLUS F. O. }
October 14, 1842. }

HENRY COLMAN, Dear Sir:—Your letter, asking an account of my operations and success in the culture of silk, was received several weeks since. A multiplicity of engagements, both at home and abroad, must be my apology for the delay in answering it.

I have been experimenting in a "small way" in the culture of silk, about five or six years, preparatory to larger operations, which I hope to make next year; and the value of this communication, (if worth anything,) must depend upon the profits of experience in mistakes, errors, bad management, and misfortune, more than upon the history of any very splendid or successful results. I have not made in any one season more than about five bushels of cocoons; and the present, only enough to supply seed for another year, as I have been finishing off and plastering my cocoonery.

First, then, as to mistakes and errors I presume I was not alone in believing a great deal that has been written and said with regard to the ease of raising worms in barns, open sheds, &c. Of the falsity of this, at least in this climate, with our changeable weather, cold nights, north-east storms, I have become thoroughly convinced. To ensure a reasonable degree of success a cocoonery ought to be finished off, and plastered to keep off rats, mice and other vermin; to be furnished with a stove to warm the room in stormy days and cold nights, and conveniences for ventilating in warm, cold weather. For the want of artificial heat, the worms will be from 1 to 2 weeks longer in going through their several changes. Mine have lingered along forty or fifty days, while others in the neighborhood with the advantage of a close room and artificial heat, have wound up in thirty-two days; and this summer I had many of my millers carried off in the night by rats, bats or something else, before they had deposited their eggs. The worms if fully supplied, will eat almost incessantly with the exception of the moulting periods, from the time of hatching until they are ready to wind up, unless they are interrupted by a temperature so low as to benumb and stupify them. The time of this interruption, I believe, must be added to their existence in the form of the worm, and that too whether the interruption is caused by cold weather or want of food. This reasoning I think will account for the fact, that worms thus treated, rise so irregularly; some are more vigorous and healthy than others, and consequently better able to withstand the effects of the cold; they therefore do not lose so much time.

I lost more than two thirds of my crop this summer by a disease which appeared among the worms after the last moulting, and just as they were beginning to rise. On the appearance of the disease they ceased to eat, became stupid, and gradually assumed a bright yellow color. In the last stages of the disease, they would burst with the slightest touch, and emit a yellow liquid and a very offensive odor. I thought the further spreading of the disease was finally checked after it had carried off thousands, by carefully picking out all that showed any signs of the disease in their appearance, and throwing them away. I attributed the disease to the want of artificial heat in the cocoonery, and to feeding the worms with the tender succulent and young leaves of the mullein, after the last moulting. I have been told by one who professed to know, that in this age, the worms should be fed only on the old and tough leaves; if this is the case, it will not do, as I have been accustomed, to cut the branches, and strew them entire upon the feeding shelves. Again, I find that the worms do better to be fed regularly and at least six or eight times in 24 hours.

It seems to me that it is to be desired that easier and better way of stifling the chrysalis should be devised than I have yet known of. I have been baking, exposure to the direct rays of the sun, direct steaming; the first I think hardens the and makes them more difficult to reel, besides danger of burning the cocoon. The second is in all cases effectual; and by the last process I had cocoons damaged or entirely ruined by the corrosion of the steam on the lid of the steam-box, thence dripping on the cocoons. The steam softens the cocoons so much that they are liable bruised and injured in spreading them out to dry, intend the next season to try the vapor of alcohol spirits of turpentine.

Even after we have succeeded in raising the worm and stifling the cocoon, there is another enemy, the bug or worm, which attacks the cocoons they have been put away out of the reach of mice rats.

A few days since I took down a bag containing bushels of floated cocoons, which had been for some time hanging up to the rafters, as I supposed, in order and in perfect safety. Upon examination of them were found to be punctured with a round hole about as large as a coarse knitting needle consequently, instead of realizing the full price floated cocoons, (\$1.00 per bushel,) I was obliged to sell them for \$2.00.

But after all this long story about failures and takes, I am by no means discouraged. I believe these difficulties may be surmounted by perseverance and greater attention, and it seems to me the great fault with writers on this subject has been that they have labored to make the community believe, that silk could be successfully made by the slipshod and careless manner which obtains in a majority of the farming operations of the day; but not so. The business, to be profitable, must be attended to, and "whatever is worth doing at all is worth doing well."

One of my neighbors, (L. L. Coleman,) has had a good crop of silk this summer, and without any accident. He showed me a few days since, as pounds of new silk of his own raising and reel which appeared to be of the first quality.

Yours, with much respect,

W. D. COOK

P. S. I cannot close this communication without requesting you to sound the note of alarm to the readers of the Farmer relative to the black canker plum trees. In a recent trip through a part of Way Cayuga, and Oneida counties, I was astonished by the great extent and fatal character of the disease. From South Butler, in Wayne county, to Syracuse in Oneida county, I did not see a single plum tree which appeared to be perfectly healthy, whereas hundreds that were entirely dead. What is the cause?

W. D. C.

Yates County Fair and Show.

The following intelligence, which we extract from a Penn Yan paper, affords gratifying evidence the right spirit is at work in that quarter.

"The 20th of October was an auspicious day Yates county. The meeting at Penn Yan on that day was a gathering of her true nobility, viz: hard-fisted, intelligent farmers and mechanics. Such a meeting has a moral in it—it is a kind of piety which indicates the tone of feeling and interest with the farmers of the country have in their own pursuit. Judging thus of the meeting on the 20th, we can infer that the farmers of Yates county are beginning to feel and appreciate the nature and importance agricultural improvement and advancement. It was the second fair ever held in the county, and it is one every way worthy and creditable to the agriculturists of the county. The improvement in stock and

last year was appreciated by all. The large number of fine blooded calves, colts, pigs, &c., on the ground, was conclusive evidence of the improvements which are going on, and which promise much for the future. But to the Fair.

Two days were pleasant—cold, cloudy, but no rain. Early in the day, people began to make their way to Penn Yan, on every road might be seen the farmers with the stock seeking in the true spirit of emulation, the place of exhibition; here a cow and calf, there a noble Durham bull, beside as a lamb and lead by the hand of a boy; and then again the quiet, innocent looking Saxony and Merino ewes, and the fine coated and prouder looking bucks; and with the lowing of the herds and the bleating of the docks, was the less melodious voice of the grunter tribe, the Berkshire, &c. of our farmers. On they came, presenting a singular appearance, the commingling of man and beast, each dressed and fitted for a gala day.

At eleven o'clock, the various yards, now full, and to the looker-on from the steps of the Court House, the scene was animating and full of interest; there, in that morning sun, were the producers, the hard-working, wealth-creating men of Yates county. Now came the various committees, and leaving them to their examinations, we will enter the Court House, and see what is there worthy of notice; and here comes the handy-work of women, to cheer and enliven the scene—the substantial uniting with the luxuries of life. Fruits and flowers, vegetable and plants, the products of the dairy and the spinning wheel and loom—here a splendid specimen of grain carpeting, with its many colors beautifully arranged—and there the substantial and tasty coverlet, bespeaking a timely preparation for the cold of winter; and then, as a climax to the whole, the beautifully ornamented lawn rug, and the unsurpassed workmanship of the ottoman and sand rugs, with their finely wrought pictures and representations, such as none but the taste and industry of woman could produce—and with these their handy craft, was woman herself, the best and bravest of all. Now, where shall we go?

Let us down for a time, for you perceive there is a rush for the Court House; the hour has come for the meeting of the society, to hear the address, reports, &c. The house is now crowded and jammed full—the President is in his seat, and the voice of the strong man has charmed the vast audience into silence and attention. Well, the address is finished, and was it not a good one—full of just sentences—of deep and well digested thought—of sound and wholesome advice, and of elevated and commanding eloquence? and take it all in all, style, manner and sentiment, it was the best, among all the good things, that we ever heard from Francis Adams. But we must hurry on—

The Monroe County Reports.

Mr. Colman having been necessarily absent during most of the past month, was unable to copy his Address for publication as soon as was expected. The pamphlet containing the address and transactions of the Society is now in preparation and will be ready for distribution very soon. The following are extracts from the Reports.

Report on Ploughing.

The committee on ploughing respectfully report,—that the number of competitors on the ground was greater than they have ever before seen—seventeen having entered the field and several were disappointed on account of the whole ground that was fit being occupied. The show of teams, ploughs and plough-eyes, was highly creditable to Monroe county, and would have done honor to the oldest and richest county in the state. But to speak of the work, the committee feel themselves unable to render that praise which the competitors justly deserve; the whole 17 having performed their work, as we think, to the entire satisfaction of the most fastidious and particular person that can be produced. The committee perambulated the ground for nearly two hours, before they could even satisfy themselves where the preference should be given, and it is perhaps a mere lottery decision as we have decided; so nearly perfect were a large number of the lands ploughed.

The committee came to the conclusion to prefer the work where the furrow slice was most perfectly

turned without any reference being had to the straightness and uniformity of the furrows; believing that the perfect ploughs leave the furrow on edge, and ordinary ploughs leave it half turned over and resting on its fellow. The committee are aware that a diversity of opinion exists on this subject, and they may be in error, but if so, it is not from any interested motive. They think the most perfect plough is the one that most perfectly inverts the furrow and buries every particle of the grass, particularly for fall ploughing and spring crops. The opposite opinion may with consistency be maintained for the ordinary summer following.

The committee therefore report the following persons entitled to the Societies premiums.

The first premium to George Sheffer, with the "Premium Plough," held and driven by John Sell. Quarter of an acre ploughed in 42 minutes.

The second premium to Donald McNaughton, with the "Caledonia Plough," held and driven by Robt. Patton.

The third premium to Charles Burr, with the "Cayuga County Plough," held and driven by O. Parker.

The fourth premium to John H. Robinson, with the "Livingston County Plough," held and driven by himself.

To Robert H. Brown of Greece, the first premium for the best work done by oxen, ploughed by Joseph Brown, with the "Wisconsin Plough."

The committee dare not trust themselves to particularize, or bestow that; raise that is due to others to whom they have not awarded premiums; as it would embrace every individual on the field; but they cannot omit to mention with great satisfaction, the work done by the Howard, Monroe County, Livingston County, Genesee County, Locklin and Scotch Ploughs, and the individuals who handled them. It is particularly gratifying to the committee, to notice the great attention and improvement in that part of the manipulations of agriculture which must be considered the base upon which the whole superstructure rests; and it speaks well for the county which has been selected as the Banner County, where is to be held the great State Fair for 1843.

All of which is respectfully submitted by the committee.

L. B. LANGWORTHY,
C. F. CROSMAN,
FRANKLIN CATE.

Extracts from the Report of the Committee on non-enumerated articles.

ATWATER'S STEAM GENERATOR.

Stephen Atwater of Rochester, exhibited an ingenious Portable Steam Generator, a new invention of his own, that promises to be of great service to Farmers. With 6 lbs. of dry hard wood it will cause a barrel of water to boil in 20 minutes. Its cost is only \$15. We award the inventor a premium of \$6.

NEW HAT KNIFE, &c.

Messrs Barton & Smith of this city, exhibited a very choice collection of Cutlery and Farming Implements, among which was a new kind of Hay Knife of their own invention, which the committee believe to be a great improvement, and they recommended it to the examination of all who have use for such an article. The committee award each of the gentlemen a bound volume of the Transactions of the N. Y. State Agricultural Society.

OIL AND CANDLES FROM LARD.

The committee would close their report by calling the attention of the members of the Society to the lard oil and stearine candles, specimens of which were exhibited from a manufactory at Cleveland, O. These two articles must hereafter attract much attention throughout the whole country. The lard oil is already

a great demand for machinery and manufactory, and has been used in several of the light houses on the lakes, and is said to burn clearer and longer than any other, while the cost is only about one half that of sperm. It has lately been discovered that oil, equal to sperm, can be extracted from lard to great advantage. After extracting the oil, the stearine remains and forms a substance similar in every respect to spermaceti, and the candles from this can be afforded for from twenty five to thirty cents per pound. These articles are already becoming quite common in the state of Ohio, where large establishments are engaged in manufacturing them, and where the nature and utility of these substances are generally understood, it will readily be seen that it must have a most important bearing upon agricultural profits.

W. C. CORNELL,
N. HAYWARD.

Rust on Wheat Straw.

It is stated in a communication on page 147 of our last number, that cattle thrive much better on rusted than on bright straw. The writer suggests that the rust affords positive nourishment; but is it not for more probable that its superiority is caused by the unthreshed grain, which, from the difficulty of shelling out, the rusted straw contains?

It is also suggested there, as well as frequently elsewhere, that a strong and sudden flow of sap hurts the straw. Would it not be simpler as well as more philosophical to suppose, that the external tissue cracks open merely from the action of outward moisture, as ripe fruits often do in rains,—instead of by an explosion? The opinion that rust is dried sap, is, I believe, satisfactorily disproved by the fact, that the microscope shows it to be a real fungus, a parasitical plant, with its several parts as distinct as those of a mushroom. And that this plant spreads by the seed, thus rendering the disease contagious, is proved by the facts stated in the communication of J. B. Bowen in the last volume of the Farmer. J.

From the Mark Lane Express.

Cheap Food for Horses.

A proposition has been made to the French Minister of War, by a M. Longchamp, to try a new method of feeding horses, which he asserts will produce a vast saving in the amount of forage necessary for the army. This gentleman proposes to make a sort of bread, three-fourths potatoes, and the rest oatmeal, with which the horses are to be fed in place of oats. The average quantity of oats for a horse per day, M. Longchamp estimates to be 10 lbs., costing about 13 sous. He proposes to replace this food by 10 lb. of the bread made with oats and potatoes, the price of which will be only 5 sous, leaving a saving of 8 sous a day. As there are 20,000 horses in the army, a saving would arise on the whole of the cavalry of 11,680,000 fr. a year. M. Longchamp considers this food to be more nutritious than the food generally given to horses, for a great portion of the oats taken by a horse are imperfectly masticated, and therefore the nutritive qualities are allowed to remain latent. Heat and moisture, he declares, are necessary to bring forth fully the qualities of the fecula of oats, and this can be procured most effectually by subjecting it to the heat of an oven, after having been moistened and well mixed up. Cakes of this kind have been long used in Holland with profit; and M. Longchamp expresses his surprise that potato-flour has not been more commonly and openly mixed with bread; bakers, he says, being in the habit of using it. But this is not the only advantage to be gained by this proposition. A hectare of oats (2½ acres) is worth about 19 fr., whilst one of potatoes produces 240 fr. M. Longchamp thinks that, if one third of the land at present under cultivation for oats were planted with potatoes, five times a greater quantity of cattle could be bred in France. By this means butchers' meat would become cheaper, and be within the reach of the generality of the inhabitants of the kingdom. The more generous diet thus procured would have a considerable influence, M. Longchamp declares, on the average height of the natives of France, which the recruitment of the army proves to be each year decreasing in stature.

For the New Genesee Farmer.

Translations from the German.

GRAPE VINE CUTTINGS.

M. Frischer, the superintendent of the gardens of the Duke of Weimar, employs with success, the following method of propagating the more choice varieties of wine and table grapes, by means of cuttings. He selects from among the stalks and branches cut away in fall and spring pruning, such as are of suitable diameter—say from $\frac{1}{2}$ to $\frac{3}{4}$ inch.—and have well ripened wood. These he cuts in pieces midway between the buds, and splits each piece lengthwise, preserving the bud unimpaired. The halves containing the buds are then placed with the flat side on a bed of well prepared garden mould, gently pressed down level with the surface, and covered with moss, or a layer of fine leaf mould. Thus planted, the cuttings speedily strike root, if the bed be kept moist by occasional waterings, and properly shaded, without obstructing the circulation of the air.

Cuttings similarly prepared, though not split, readily strike root and produce vigorous plants, if their ends be dipped in melted sealing wax, and they be planted in good garden soil, covering them in to the depth of half an inch. The ground must be kept moist, and free from weeds.

GRAFTING.

M. Schroer recommends using a branch of common willow, an inch or two in diameter, in the following manner, as a matrix for receiving the grafts of such varieties of apple, pear or quince trees, as it is desirable to multiply. Make longitudinal cuts or slits through the branch, at equal distances of 15 or 18 inches. Take grafts having two perfect buds, give the lower end the usual wedge-shape, using a keen knife, and insert them in the slits of the willow, making the lower bud sit close to the slit. Then bury the branch in a trench formed in good garden soil of such depth as will permit the upper buds to protrude just above the surface of the ground, when the trench is again filled. The ground must be watered occasionally if the season be dry, and weeds must be carefully extirpated whenever they appear. In the spring of the following year, the branch may be taken up and cut in pieces, leaving a small portion to each of the growing grafts—which are to be replanted in a nursery. The willow does not form a permanent union with the grafts; but merely supplies nutriment till the proper fibrous roots are produced from the lower bud.

POTATOES.

M. Bellamy Aubert, of France, states, as the result of experiments continued during three seasons, that abundant crops of potatoes may be grown in poor clayey soils, by simply sowing the sets plentifully with rye-chaff previous to covering them with earth at planting.

Professor VOLKER, of Erfurt, covers his potatoe sets with a layer of tanners' spent bark, two or three inches thick, before turning a furrow over them. He says he thus provides a loose spongy bed for the young tubers; prevents weeds from springing up and growing in immediate contact with the plants; and secures an abundant supply of moisture during the season, if but one soaking rain occur after planting—as the spent bark, covered by the surface soil, will retain water during the most protracted drought.

FRUIT TREES.

Dr. Zimmerman, of Zinzow, alleges that the natural productiveness of fruit trees is injuriously affected by the practice of training standard trees high, or pruning off the lower side branches. This training is usually commenced in the nursery, and continued even after the tree is transplanted to its permanent position in the orchard—resulting in giving the tree a

main stem 6 or 7 feet high. Dr. Zimmerman contends that trees of the same class or variety, thus trained, are never so productive as those which are suffered to assume a more natural form and development; and he refers, in proof of his theory, to the fact that orchards belonging to persons who know little of the modern scientific refinements in horticulture and whose trees are very scantily pruned, are invariably more productive than those whose owners keep them in regular subjection to the knife. Permitting trees to branch out lower, would perhaps involve a greater waste of ground, in orchards especially; but the increased productiveness of such trees, would, in the Doctor's opinion, abundantly compensate for this. There are moreover many plants which could be advantageously cultivated in the shade of such trees.

The truth probably, in this case also, lies between the two extremes—and possibly the whole matter may resolve itself into this, that the more horizontally the branches of fruit trees are trained or permitted to grow—which appears to be Nature's tendency—the more productive of fruit will the trees be. In training fruit trees against walls, it is known to be advantageous to give the limbs a descending curve. This effect will be naturally produced, if the trees be permitted to branch out nearer the surface of the ground than is customary. The limbs, in this case, assume a nearly horizontal direction, and are subsequently curved down by their own weight and that of the fruit they produce, and the result of the whole is, a greater tendency to the formation of fruit buds.

MADDER.

The proprietors of small farms in the Grand Duchy of Baden, cultivate madder, of late years, with much success and profit. The plant requires a rich soil, free from weeds, and the root yields a beautiful and durable red color only when it is permitted to attain to perfect maturity in the soil—which is not till the close of the third year of its growth. Roots of one year's growth are indeed used in Avignon, but the dye prepared from them is not durable; and that from two year old roots is very little better. Good madder, yielding a rich and durable dye, can be prepared only from roots not less than three years old; and if two of the summers were very hot, the dye will be the brighter and more permanent. When it appears that the summers are unusually cool, the roots are not taken up till the close of the fourth season. Southern plants, acclimated and cultivated in northern latitudes, require great care and judgment in their treatment, to prevent deterioration; and the madder plant does not appear to be an exception.

FROZEN POTATOES.

The results of repeated experiments show that potatoes injured by frost are not rendered valueless; but that very good flour or meal may be prepared from them, if the weather continue sufficiently cold to permit of repeated thawing and freezing. By this process, properly conducted and continued, the watery particles are expelled, and the inner of vegetable substance is gradually converted into meal. Exposure to rain and snow is injurious only as prolonging the operation. The meal or flour thus formed, can be readily separated from the outer skin or peel. M. ENSMOFF exposed soft watery potatoes to the action of frost in this manner, and obtained a very superior flour, which was preserved in good condition for two years, even in a damp cellar. When it happens, in consequence of the unusual severity of the season, that large quantities of potatoes are injured by frost, excellent and nourishing meal may by this process be prepared therefrom, with very little expense or trouble.

Travellers relate that, in the native country of the potatoe—the more elevated and colder regions of Peru

—the inhabitants expose quantities of this vegetable to the action of frost, for a similar purpose. After repeated alternations of freezing and thawing, the whole mass is thrown into a kind of vat and well kneaded or trodden wth their feet to separate the skins or peels. It is then put into coarse bags, and placed in a stream of clear running water, where it is left three or four days. When taken out, it is spread as thin as convenient and dried in the sunshine; and thereafter ground into flour.

Professor PUCK, of Leipzig, in his Archives of German Agriculture, recommends that the same method be employed when apples, pears, or turnips are accidentally injured by frost.

Potatoes are neither so productive, nor of so good quality, in warm as in cold climates. In Spain and the south of Italy, the vines are thicker and longer, and the foliage more dense and luxuriant than in the more northern countries of Europe where this vegetable is cultivated; but the tubers are smaller in size and fewer in number. In Colombia, large potatoes and abundant crops are produced only in the more elevated mountain regions—rising from 8000 to 10,000 feet above the level of the equatorial seas. The same appears to be the case in the United States—the potatoes of Maine greatly excelling those of the middle or southern state in quality and flavor, and the average crops are much more abundant.

ITALIAN RYE-GRASS.

In the Grand Duchy of Mecklenburg, the Italian Rye grass (*Lolium perenne italicum peristatum*.) is found to be far superior to, and much more productive than, the English Rye-grass. Early in March it presents a rich, green, and vigorous appearance. The stalks and leaves are soft and juicy, and it is fit to be cut for hay early in June. The second crop produces a large quantity of seed, if cut early in September; and the after growth yields plentiful and succulent pasturage. The seed is smaller than that of the English Rye-grass; and when produced from the second crop, is generally very clear and pure. The Italian Rye-grass would probably be valuable for forage, in northern districts, as it is sufficiently hardy to stand the winter. For soiling cattle it is found to be particularly valuable.

HORSE CHESTNUT HEDGE.

Wenzel Hamneck, of Morevia, recommends the Horse Chestnut, (*Aesculus hippocastanum*) as best adapted for forming a hedge impervious to men or animals. The seeds, when gathered, are spread out in a dry and airy chamber for a few weeks. They are then planted in a shallow trench formed by a hoe or a plough, dropping them four or five inches apart in the row, and covered with earth. The young plants will appear about the close of the ensuing April, and should be kept well weeded. In the spring of the third year, before the sap begins to flow, the stems are bent across each other so as to form a kind of wickerwork, and bound firmly together at the crossings by means of willow twigs, or bies. If this be well done, the trees unite permanently at those points, forming a lasting and impenetrable fence. By proper care in the subsequent pruning of the hedge, denseness can be greatly promoted, and a neat and handsome appearance imparted to it.

On Animal Manures.

(Translated from the German.)

The bones of different species of animals differ much as to their component parts, and therefore are not of the same value. As far as nitrogen is concerned, the bones of cattle are the best, whilst those of horses and sheep are preferable on account of the greater amount of phosphate. Those who use bones as manure should bear that in mind.

As far as the use of bones for manure is concerned, it is requisite that they should be previously reduced

into the finest possible dust, which, however, is a difficult operation, on account of the toughness of their cartilage. The operation is performed by pounding or grinding, sifting the dust, and pounding and grinding the coarse pieces again. Fine pulverisation is absolutely necessary, in order that the cartilage may be the sooner dissolved in water, and the phosphoric lime in the acids of the soil. The coarser the dust the more it will take to manure a certain area; the finer, the less; however, the coarse powder will not last for a longer period. Of fine bone dust, 700 lbs. or 800 lbs. will suffice for the Magdeburg acre; of coarse, 1200 lbs. to 1500 lbs., especially if an immediate effect is expected. Heavy clayey soils will require more than light loam or sandy fields; and if bones are to be used efficiently upon dry sandy soil or in humus, the bone dust must be first mixed with umous earth, and be left to rot, as we shall state hereafter. Bone-dust always acts best if brought into close contact with the roots, and should therefore either be harrowed in with the seed, or used as a top-dressing. In England, it is drilled in the ridges, where the farmer sows. 700 lbs. of bone dust will even last three years, as I have found by several experiments; the first year, however, the action will be the most if the season has not been too dry. It has been assumed, that 200 lbs. of bone-dust are equivalent in their action to 500 lbs. of dry manure, which, however, is a very uncertain calculation, for the quality of the manure must be taken into account.

If bone-dust is not properly, it is necessary that soil should not be deficient in humus and moisture; because both cartilage and phosphate of lime are substances with difficulty dissolved in water; the latter especially being only soluble in water by the aid of humic or carbonic acids derived from humus. Moisture is also indispensable, because it is necessary to bring about the change of cartilage to ammonia and carbonic acid. Humic acid is of equal importance, for the sake of neutralising the ammonia generated from the cartilage and fixing it. If then manuring with bone dust has been occasionally found to be unsuccessful, it may have been caused by the deficiency of humus or moisture. To be certain, then, that bone-dust will produce the desired effect in a dry soil devoid of humus, it is always best to mix it with umous earth and to throw them into a hole. This mixture being kept wet will become rotten, much umous of ammonia will be formed, and it may then be used as a top-dressing, or be harrowed in with the seed. Bone-dust will become equally efficient if previously put into a urine-tank and permitted to decay. The phosphate of lime will thus be decomposed by carbonate of ammonia that arises from urine, the salt of which will be the generation of phosphate of ammonia and carbonate of lime. The former salt is very soluble in water, and will therefore—even if there be but little humic acid in the soil—easily provide plants with the necessary amount of phosphorus, as well as nitrogen. Experiments which I have made with the phosphate of ammonia have shown that it is very beneficial to plants. It has been also recommended, when bones have been merely crushed, to mix them with quicklime in a ditch, and to let them rot there; but this process is bad. The consequence is, that the whole of the ammonia developed on the cartilage will escape as gas. Equally objectionable is the plan of packing bone-dust in heaps before using it, wetting it, and letting it rot in that state; because, in this instance also, the ammonia will assume the form of gas. If, on the contrary, as shown above, umous earth is mixed with the bone dust, and ammonia will be fixed by humic acid. If the soil contains much fat, a sort of ammoniacal soap, easily soluble in water, will be produced. Those vegetables will be most advanced by manuring with one dust in which much nitrogen, phosphorus, and chlorine are to be met with, to which class belong all sorts of cabbages and turnips, wheat, trefoil, beans, peas, and vetches. Used on meadows, bone-dust brings up different species of trefoil and vetches, and the same time generates a rich herbage, much relished by cattle. It has been objected to bone manure, that it brings to the land worms and insects which destroy the crops; but this will not be the case if the bone dust has been previously mixed with humus earth, and is thoroughly rotted; because, in that case, the cartilage, which attracts the worms and insects is decomposed. To lighten a clayey soil by coarsely used bones, as some have suggested, is, at the high price of bones, quite out of the question on account of the expense.—*Farmers' Journal, Eng.*

Good Reason.—A secretary of state being asked by an intimate friend why he did not promote merit, replied, "Because merit did not promote merit."

Ridge versus Flat Drill.

To the Editor of the *Doncaster Gazette*:

Having heard various discussions on the relative merits of ridging and flat drilling white turnips, I resolved this year to bring the matter to the proof, by trying the experiment in two or three fields. I tried in one instance flat drilling on land which had laid a fortnight against ridging and drilling on fresh mould; the flat 16 inches apart, the drilled or ridged 27 inches apart. They were both carefully hoed and singed; but the flats yellowed very early and stopped growing; whilst the ridged luxuriated in their ample space, and grew to an uncommon size; the difference in the weight of crop per acre is to the amount of some tons. Adjoining these I ploughed down manure, and drilled on the flat, but they scarcely did better than the other, though they had all the same top dressing; whilst the ridged ones, immediately contiguous, with the same quantity of manure, did exceedingly well. A few further observations I made on these experiments may not be without interest; we took a few loads of dung, or rather litter, fresh from the fold, the exact soil that modern science so greatly approves, but the turnips rejected the new fashioned views, and grew both easily and tardily; indeed the difference was astonishing between this and Christmas-led and once-turned manure. In the same field some were not rolled, some done with a wooden roller, and some with a heavy stone one, across. The effect on the turnips was slight, but on the weeds important; for, just according to the weight of the roller, had the weeds been repressed in their growth.

Should these observations be worthy a place in the *Gazette*, you will, by their insertion, greatly oblige yours, &c.

AN 1 LONIAN.

P. S.—I venture an assumption for the purpose of eliciting remarks from some of your numerous readers, that fold manure requires more vegetative qualities during the process of fermentation than it loses by the escape of ammonia.

From the *Albany Cultivator*.

Water Lime—Cisterns.

Charles Merrivether, of Graysville, Ky., requests some "information as to the burning water or hydraulic lime, the best sand to mix with it, and the mode of making cisterns."

Hydraulic lime is burned in the usual manner, but as it will not take like common lime, it is ground to fit it for use. Hydraulic lime varies so much in quality, that no general rule can be given as to the quantity of sand it will bear in making cement.—When good, the 4 bushels of sand to one of lime, will be the proper quantity, although some use more sand. The sand should be sharp and clean. There should be no clay or loam among it; since if these be present, the cement will not have the requisite hardness, or set quickly. The best method of making cisterns, is to dig the excavations of the proper size and depth; then make over the bottom a firm floor of stone, or brick laid in cement. (A single flat stone like those used for paving, that will make an entire bottom, is the best,) and on this foundation build the wall of stone or brick for the reservoir. Whatever may be the material of the wall, it should receive one or two coats of cement on the inside, to insure its being water-tight. Some, in making cisterns, place the cement on the earth of the pit, using neither stone or bricks. Where the ground is very dry, and the sides can be made smooth, this method, where two or more coats of cement are used, may answer; but in general, the best way is to construct a wall as above directed. The cistern when made must be covered so as to be secure against frost. In making the cement, it must not be wet up, or prepared, faster than it is wanted for use, as lying for any considerable time spoils it.

We recognise below the hand of an old friend, whose authority is unquestionable.

From the *New England Farmer*.

Seeding on Green-sward Furrows.

MR. PUTNAM.—In your paper of the 31st of August, there is an inquiry, in what part of the State the experiment has been made of seeding on green-sward furrows, and how the farmers liked the practice. We are disposed to give "Essex" information concerning our experience and practice, without participating at all in the dispute whether this be old or new husbandry.

Some twenty or twenty-five years since, the writer was told that Mr. Z. Estlin, of Hanover, produced ploughing award bound fields, manuring and seeding with grass, without any intervening crop. The first

suggestion of such a course was sufficient inducement to make an experiment, as much fruitless labor and expense had been given in attempts to raise grain crops on cold and clayey soils. Every experiment made has been attended with very satisfactory results. There is no loss of crop in the course, and yet most of the purposes of naked fallow are fully accomplished. The gradual dissolving of the soil prevents the soil from falling into too compact a state, (a common evil on low lands) and imparts nourishment for many years to the new grass. We have a field which was ploughed and seeded in August, 1825; it has not been very frequently or copiously dressed with manure, and is still in better condition than mowing fields generally. Another field, seeded twelve years ago, and dressed once in two years, produced this year a very large first crop and a second is now ready for mowing.—This practice is worthy of all commendation on land not suited to grain crops. Where Indian corn would be likely to grow well, we should think it a more economical and better course to plow in the spring, supply manure, plant with corn, cultivate with a level surface, and sow grass.

"Essex" seems disposed to blame farmers for neglect in communicating to the public, if the system concerning which he inquires, has been pursued "for a long course of years." Remissness in communication is no doubt an easily besetting sin, and the writer will not deny that it sometimes lies at his door; but on this subject there is no conscientiousness of any improper reserve on his part; all suitable occasions have been embraced to direct the attention of farmers to a practice so intimately connected with their interests and prosperity. All practicable publicity has been given to views entertained on the subject. In an account of the cultivation of the writer's farm, which was published in the *N. E. Farmer*, vol. 2, page 360, this practice was mentioned as part of the system pursued. In the county of Plymouth, the practice has not been extended proportionate to its utility; but we have the satisfaction of seeing a good number of farmers every year adopting it, and where one experiment has been fairly made on a farm, an intelligent owner will be very certain to repeat it.

M. ALLEN.

Fenbrook, Sept. 2d, 1842.

Fair County Agricultural Society.

The second fair this season, of this Society, was held at Buffalo, Nov. 16th, for the exhibition of grain and root crops. The following are the awards of the viewing committee:

ROOTS.

Best one quarter acre carrots, 1512 bushels to the acre, Manning Case, Black Rock, \$3.

Second best one quarter acre of carrots, 1040 bushels to the acre, Abner Bryant, Black Rock—Diploma.

Best one quarter acre ruta bags, 1000 bushels to the acre, Abner Bryant, Black Rock, \$3.

Best one quarter acre beets, 1280 bushels to the acre, Abner Bryant, Black Rock, \$2.

JOHN WEBSTER,
JOHN CARPENTER, } Committee.
DAVID P. WHITE,

GRAINS.

Best acre corn, 57 bushels to the acre, Thomas C. Love, Newstead, \$4.

Best acre barley, 42 bushels to the acre, John Carpenter, Wales, \$3.

Best acre oats, 67 bushels to the acre, John Webster, Hamburg, \$3.

DISCRETIONARY PREMIUM.

To Manning Case, Black Rock, one-half acre corn, 51 bushels to the acre—Diploma.

A. CALLENDER,
A. BRYANT, } Committee.
WM. HODGE, Jr.,

The attendance was very small, owing probably to the bad state of the roads. There was no application for the premiums on wheat, rye, buckwheat, peas, beans or potatoes. And on the articles to which premiums have been awarded, there was no competition. The samples exhibited, however, were superior.

WARREN BRYANT, Sec'y.

The late Thunder Storm.—A curious incident occurred in a crowd: the finger of an individual suddenly became light, and was conducted with electrical velocity into another person's pocket, when being attracted by the metal, it struck upon the whole of it, and then glided off, so that the bolt which usually follows was quite in another direction.—*Punch.*

Mediterranean Wheat.

MR. COLMAN—Practical farmers have been so often imposed upon by humbugs, in the shape of new articles of agricultural produce brought to their notice through the columns of agricultural papers, that they have formed a distrust, and justly too, of all such communications, especially when they find at the bottom, the very disinterested offer of "only a small quantity" for sale at the moderate rate of four times the market price of the same article. And I will take the liberty to add, that the publication of such communications, and particularly when upon trial they prove to be sheer impositions, tends greatly to lessen the character and influence—yes, and the circulation and perusal of agricultural periodicals, and forms one of the chief arguments brought up against what is called "look farming."

I am led to these remarks by reading in your truly welcome Genesee Farmer for September, the article headed "Mediterranean Wheat," from the Hon. H. L. Ellsworth, the very worthy Commissioner of Patents at Washington City.

As one humble individual practically engaged in farming, I have much admired the indefatigable exertions of that gentleman to promote the agricultural interests of our country, and I doubt not, I shall be joined by the mass of farmers throughout the Union, while I most heartily tender him my thanks therefor. I hope and trust that his great zeal and devotedness in the cause, may not get the better of his judgment, and lead him into errors or statements, the publication of which he may at some future time regret.

The new variety of wheat which is now brought to the notice of the wheat growers of Western New York, is recommended as being "proof against the fly and almost proof against rust." Mr. Smith gives us no reason why the fly does not attack the Mediterranean Wheat,—indeed he says frankly, that no explanation can be given,—but he knows it is so and that is enough. I regret this, for I should be pleased to see how he would set himself to work to account for it.

Now, sir, such an argument, or rather, such a statement, has no weight with me, and I doubt whether many Western New Yorkers will be found willing to pay two or three dollars per bushel for his wheat upon such a recommendation. They know too well, that Mr. Fly is not a discriminating gentleman, but will attack the wheat plant without regard to varieties or high sounding names,—or whether it be "far fetched and dear bought," or the humble production of our own soil. In the other recommendation, its being "almost proof against rust," there is somewhat of plausibility, if this wheat does certainly ripen ten or twelve days earlier than any other variety.

The yielding qualities of this wheat, the most important item with the wheat grower, are stated only by guess-work. Mr. Smith says he has cultivated it after corn and potatoes, and that after the potatoes *he thinks* yielded full 30 bushels per acre,—but does not even guess at the yield after the corn.

If he wishes the farmers of Western New York to purchase his wheat at an exorbitant price, why did he not measure his ground and his crop, and state the exact result? Why did he not state the kind and quality of soil—the course of cultivation—the time of seeding—and the time of harvesting?

J. HORSEFIELD.

Castile, Wyoming Co., N. Y.

In the main, we perfectly accord with our friend Horsefield, but we think we should not let his communication go without some qualification. In respect to editorial responsibility perhaps he demands too much of us. What we publish under our own name or authority, we are entirely responsible for. What we publish, though it may be mere hearsay, in a style of encouragement and in a way to imply that we credit it,

we are to a degree responsible for, at least so far as our character for good judgment is concerned. But what we publish under another man's name, he and not we are wholly answerable for. Mr. Smith and Mr. Powell are responsible for the statements to which their names are attached. We confess ourselves incredulous in regard to the peculiar properties of the wheat recommended, because, first, the statement seems improbable; next, because no reason, it is admitted, can be given why this wheat should not be as subject to the fly and the rust as other; and third, because we do not know personally either of the gentlemen mentioned and the offer to supply the seed, (though not our friend suggests, at an exorbitant price.) would lead to the inference that some self-interest was at the bottom of it. But we do not think the inference is a very strong one. What it is every farmer can judge for himself; and a very small quantity of the wheat for trial, say half a bushel, would not be likely to involve a farmer in any ruinous risk. We think it clearly worth the trial. As to Mr. Ellsworth, his disinterestedness in the case is beyond all question; and his zealous efforts for the agricultural improvement of the country, entitles him to universal respect and gratitude.—Ed.

Moral and Intellectual Culture.

Having in my last communication, touched but slightly on what I conceive to be the duties of mothers, I would now invite their attention; incapable though I am, of doing justice to this subject, but the importance attached to it, induces me to endeavor to arouse the slumbering mother, to engage in the cause of intellectual cultivation, and thereby pave the way for all the innocent pleasures and exalted enjoyments the immortal spirit of man was originally designed to delight in and aspire to.

The mother! how much is expressed in that one word. With it is associated all the most tender, refined and lovely feelings of our nature. And who that reflects upon the station she occupies, can doubt that a vast accountability rests upon her. Mothers have you pondered this responsibility! When Heaven placed in your possession that infant form, think you not, no fearful responsibility arose from that relation? To sustain in the situation which you occupy with innocence and a clear conscience, is a subject of infinite importance to yourself, to your family, and to the community. For it you must answer to God, who imposes the duty.

Does the mother that feels her children a burthen, the cares and labors she must endure for their sake as grievous to be borne, does she fulfill the manifold duties Heaven demands of her? No! with these sentiments and feelings, it is impossible. There is no one thing, in my opinion, in which there is so much wrong, so much contrary to what it should be, as the principles and feelings imbibed by mothers toward their children. I have seen many a mother that appeared to feel justified in considering a family of children a curse. And why? Because such mothers do not study into the designs and intentions of the Almighty, in instituting the dear and near relation of the mother to her child. They seem not to discern the wisdom and goodness of God—the unbounded mercies and blessings of Heaven, when mingled with the bitter pangs of bodily anguish and mental suffering. Yet the deep fountain of a mother's love will gush forth in constant anxiety, care and labor, in a sacrifice of almost every ease and comfort for their children. This shows plainly and conclusively, that the mother possesses within her own breast, a faithful monitor, which, if adhered to, would direct her not only to provide for their physical wants, but to labor more earnestly and abundantly for their progress in morals, in religion, in that which serves to enlarge the affections for the good and just, and enlighten the mind with the beams of nature's laws and spiritual wisdom.

In that receptacle of anxious care and self-denial, of affliction and tenderness in a mother's heart, there should also reign high moral principle, self-acquaintance and self-control, and with these a consecration of all else, to the laws and requirements of the gospel.

In a family little can be effected in the cause of mental improvement, unless the parents act in concert. Take a wife that is fretful, worldly and selfish, and you will soon perceive that all the efforts of the husband are rendered abortive. And also, if a wife be ever so intelligent and active, if she has a husband whose soul never breathed one aspiration or desire for any greater good or better knowledge than wealth can bestow, how little can she accomplish. But even then I would say, try. Never despair of good. Perhaps the husband or the wife might be induced to overcome the wrong sentiments they have cherished, if they should behold in their companion an example of steady devotion to the intellectual and moral improvement of their children and family.

I am well aware, that farmers' wives have much to engross their attention in their business; and a great amount of care and labor to endure. But the next question is, are they obliged to subject themselves to such hard duty. The great difficulty is, that mothers allot to themselves far more labor than they ought to undertake. You task yourselves, in my opinion, far beyond your duty; the physical powers to much, the mental too little. It is not uncommon to see a farmer's wife do her kitchen work, washing, ironing, baking, cleaning, &c., the knitting, sewing, spinning and weaving for the family, with the assistance perhaps of a few weeks labor, or some little help. And this, very probably, by one who is abundantly able to afford herself leisure for meditation and reading, for attention to her children; in a word, to intellectual cultivation. But not they do not possess all the world yet, and until they do, she must toil and labor as unceasingly as if her children were starving for a morsel of bread. Is this right? Is it doing justice to yourself and your family? Is it fulfilling your duty to God? Hercules strength could scarcely endure it. The most healthy and robust feel that they are old while yet young, when subjected, year after year, to so much excessive fatigue and labor. And the half of the difficulty lies not here. Its greatest evil exists in the prostration it affects on the intellectual powers, and religious and moral principles of the heart. One of the fundamental principles in the science of phrenology is, that the organs that are most exercised will develop the most largely, and thereby become the moving springs to action, the most likely to control the whole tenor of our lives; while the neglected faculties, or organs, will perish and decrease, until they are scarcely perceptible. Now whether this science is real or imaginative, as some suppose, I will not attempt to discuss. But I do know, from my own experience and observation, that any of the passions, will, by frequent indulgence, become habitual; and what becomes a seated habit cannot be overcome, without a powerful and persevering effort of the mind. And I also know, that if through carelessness or indifference, we neglect to cherish the tender and benevolent sentiments of the heart, we become cold and selfish; our indifference increases until it becomes a seated principle of the mind and a striking characteristic of the person. I have but just broached the subject, and leave it with regret for the present.

FLORA.

A Sign of Better Times.—Mr. Jonathan Wilson, of Shroton, Vt., lately received two hundred dollars of Solomon W. Jewett, Esq., of Weybridge, for a Pauler Mermu Buck.

Herbs for drying or for distilling should be cut before their flowers expand, and the former laid thinly in a shady place.

Pedantry, says Coleridge, consists in the use of words unsuitable to the time, place, and company.

We have already got somewhat involved in the question of Protection to home industry; but we are not willing to refuse our respected friend Garbutt a place in our columns. The question is in every account, a most interesting one to the farming community; but we do not mean to admit its claims to the prejudice of other important matters, and will not permit it to assume a partisan character. For ourselves, we think the root of the whole matter lies much deeper than either of our correspondents have yet reached. The common arguments, pro and con, are quite hacknied, and we wish they would go into deeper waters, or rather look at it from a higher vantage, far above all the smoke and dust of party conflict.—Ed.

The Tariff.—In Reply to S. W.

MR. CONYER.—Your fluent correspondent S. W. is so constantly dabbling with the tariff, and is so courteous towards John Farmer for not thinking as he does, that I am compelled to suspect that he is determined to make the columns of the Farmer subservient to his political views, and is so anxious to confute his antagonist that he sometimes forgets himself.

I will take the freedom to notice a few of his statements in answer to John Farmer. He says—had he (John) been as well informed on the subject of our national tariff as he is refined and witty, he would have known that the high tariffs of 1828 and 1833 did not receive even a majority of the votes of the New England States.* Now if S. W. had not been so anxious to expose John's ignorance, he would not have made such a blunder as to class the tariff of 1833 with that of 1828, as a high protective tariff. So far from that of 1833 being a highly protective tariff, it was an abandonment of the protective system and a repeal of the tariff of 1828. This has been one of the principal causes of paralyzing our industry and bringing the country into its present state of stagnation, depression and embarrassment. It is true, as S. W. states, that the tariff of 1833 did not receive even a majority of the votes of the New England States, for the six states had 20 votes in the House of Representatives, of which there were only ten in favor of the bill, viz: 6 from Maine and 4 from New Hampshire; one from New Hampshire being absent. The remaining 25 voted against the bill. Now if this strong vote of 25 to 10 against the abandonment of the protective system and against the repeal of the tariff, is a proof that the New England States are not in favor of a protective tariff, S. W. has a strong evidence of the fact; but to me it has rather the contrary appearance. In the next paragraph he classes the tariff of 1833 with that of 1816, either to show John's ignorance or his own knowledge. The one was about the commencement of the protective system, the other its abandonment.

Again he says "John Farmer asks 'why are our New England factories closed and their hands unemployed at this time?'" He lets a manufacturer of his own town answer, by stating "that a protective tariff would not help them, for they have the whole of the home market without foreign competition;" but here S. W. has left a hole to creep out at, for the manufacturer who gave the answer, is one of coarse cotton goods; his answer, therefore, is correct, as far as that kind of goods is concerned. But, Mr. S. W., John's question was a general one, and applied to all our branches of manufacturing industry, and you gave the answer as such, which goes to say that our manufacturers are not interfered with by foreign competition.

Again he says "the difference of opinion between John and myself is simply this, I want all our great national interests, agriculture, manufactures and commerce, protected by sound and equal laws, but he seems to embrace the delusive notion that we stimulate the manufacturer by taxing the other interests." Now Mr. S. W. if our manufacturers "have all the home

market with a fair demand for export," how can a protective tariff be a tax on the consumer? Were there a duty, no matter how heavy, laid on imported ware or air, I do not think that it would be much of a tax on us, who do not inhale it.

S. W. is correct when he states that "John Farmer does not know that the manufacturing interests of the United States have been fostered more than any other interest." Nor does any other man, for commerce has received hundreds of dollars as protection where the manufacturer has received one.

Again he says that "so far from specie going out of the country, it never goes out when it is indispensable for a currency at home." If so a poor and needy community will never want money. This is to me rather a new notion; and I should guess that some of our Western States will soon have a plenty of it, for they have been pretty destitute of a currency of any kind for some time. This is a wonderful age for new things and wonderful improvements; it was formerly the notion of its working folks, that a community would be rich just in proportion as they were industrious and economical, and that in proportion as they bought less than they sold, and earned more than they spent, that they would have money plenty, independent of "paper rags," African shells, or any other substitute.

But I would ask S. W., and every honest and candid man, what is the reason that the experience of this country for the past 20 years must be set at naught, and we yet keep prating and writing about protective tariffs and free trade, as if they had never been tested by experience, and as if there was nothing for us to do but to talk and write.

When the "abominable" tariffs of 1822 and 1828 were passed, the country was made to re-echo from one end of the union to the other with their anticipated dreadful effects. Our commerce would be destroyed, our ships rot at the wharves; our laborers would be made dependent beggars; the farmers and merchants would be ruined by the enormous taxes that they would have to pay, to raise up a manufacturing aristocracy. Well, what was the result; those tariffs went into operation, and strange to tell, none of these dire effects followed, but the very reverse occurred in every case. There never was a country more prosperous, nor one where labor and skill were more liberally rewarded than in the United States from 1822 to 1832. Then commerce increased with a double ratio; our cities advanced with rapid strides; laborers of every class found employment and ample compensation; our farmers and merchants were prosperous; and the country advanced rapidly towards wealth and prosperity. Our currency was as sound and as good as it could be; it was not surpassed in the civilized world; a dollar at one part of the Union was a dollar at the other, and by paying the postage of a letter, "our paper rags" could be converted into gold or silver at the pleasure of the holder, and the facilities for exchange were such, that distance was scarcely realized by our merchants. But our wise and knowing ones were not content with this state of things. We must have a change, and with that change we were to have a better currency, and better times for every thing; but we must have a change, and a change we have got. Yet I fear that it will be a very hard matter for even our wise and knowing heads to tell wherein that change has benefited the country since 1832.

Yours, most respectfully,

WILLIAM GARBUTT.

Wheatland, 1812.

For the New Genesee Farmer.

Protective Tariff.—No. 3.

Another reason urged in support of a Protective Tariff is, that it will prevent a consequent drain of our specie. The argument that a prohibition of imports

would permanently increase the amount of specie in this country, in its practical effects, would ultimately destroy all commerce, and in my judgment, it is wholly based upon the false premises that we can sell every thing and buy nothing. I grant that when a nation buys a large amount more than they sell, that the coin must be exported to liquidate the debt, but the next year's purchase of the debtor nation will undoubtedly be enough less than the former, to restore the equilibrium of the commercial world, which can be accomplished in no other way than by a return of the specie to that nation where there is a deficiency and the greatest demand. There it will assuredly find its way, because, like every other article of commerce, it must go where it commands the highest price.

But suppose that we levy an additional duty of 20 per cent. on all articles which we consider the absolute necessities of life, the result would be an increase of price in our market. Cannot the British manufacturer sell to some extent as before at the same profit, by merely paying into our Custom House the additional 20 per cent. tariff, and reimburse himself by being enabled to sell his goods at the advance price? Another reason urged, is that England and other countries will not admit our bread stuffs without paying enormous duties, and that if we were to retaliate, it would of necessity compel them to come to terms of reciprocity. This I believe is the natural feeling of all. It has been the last and most difficult point for me to relinquish, for I was once in favor of a Protective Tariff and a credit currency. I still hold myself open to conviction, and if I can be convinced that my present views are incorrect, I am ready to relinquish them, believing that I am not one of those who if "convinced against his will is of the same opinion still."

If I mistake not, we have tried the retaliating system once, and I would ask what evidence is there, that we shall be more likely to succeed upon a second trial; and is not the tendency of public opinion in the old world altogether in favor of free trade principles; are not all parties in England scheming eagerly to get rid of the system, on account that the mass of the people can no longer sustain life under its oppressive burden?

Do not the starving millions attribute our prosperity to the practice of Free Trade by our Government? Shall we disappoint them by our example and deprive them of every hope? Shall we return to a system of taxation that is the cause of the premature death of 20,000 human beings annually? and that too on our small island of our own kindred blood?

But admit for argument that the retaliating system would bring England to our terms of reciprocity, what would be the effect upon the price of Bread stuffs? would the price here materially advance? would we not then come in competition with wheat from the Baltic, from Russia, Germany, Poland, and all other grain growing countries, and that too where labor is cheaper than with us, and even less than it is in England? How can we then compete with either of those Nations in a foreign market, under any system of high prices?

I take the position that American labor must absolutely come in competition with that of Europe, unless we adopt the Chinese policy, and destroy all commerce and live entirely within ourselves, (a system wholly impracticable to adopt in this enlightened age).

What are we to understand by commerce; is it not an intercourse of trade and an exchange of products or manufactures between the several nations of the Globe? and how can we exchange our products and manufactures for dry stuffs, hides, or West India goods, with Spain, Mexico, or the South American States, without meeting England and all other commercial nations in competition for the same trade? And how can we exchange products with Russia, France or

Germany, but what we meet England there in competition for the same trade.

If we go to Africa, we there find them, or to the "utmost parts of the earth, there are also." If we levy a duty to protect our own manufactures, the prices are raised in our own market, (as I think I have clearly shown) they can then compete with us, and if we prohibit them altogether they will smuggle their goods among us, and if they dare, they would fight us in the bazaar, as they have China, if we debetted them in the act.

I confess that at the first view it appears inconsistent that we should admit the products of England on better terms than they admit ours; but shall we injure ourselves in order to retaliate against them? Shall we, because England oppresses the bulk of her population by excessive taxes on their bread, make the majority of our citizens pay excessive taxes on their manufactured goods? and is it a good and sufficient reason for so doing? I think not. Why is it that England takes the landed interest into such special favor by way of protection? It is because the monied men—the Lords and Nobles have monopolised all the land of the Kingdom, and they frame all the laws to advance their own interest and force their hard earnings from the mass of the people.

The English nation possess much greater natural advantages for manufacturing than for agriculture, on the account of a dense population and their limited territory at home, which is easily monopolized; consequently the mass of the people must necessarily be engaged in manufacturing. The law makers, therefore, in order to carry on their extensive wars and support a splendid government, have made the manufacturer bear the brunt of taxation, on the ground that these individuals, possessing natural advantages for producing wealth, can bear more taxation and sustain life, than individuals who do not possess those advantages.

Monroe, Mich., 1842 J. S. DUTTON.

Protective Tariff.—No. 4.

The Wool Growers, more than any class of farmers, seem to favor the Protective Policy. Do they think that an advance of 10 or 20 per cent. to the present duty on wools, would ensure them for all time to come, the same increased ratio of prices? If they do, they are greatly mistaken. Do the manufacturers go for the same duty on the "raw material?" and if they did, competition at home would soon reduce the price of wool to the old standard, if not below it; and at present prices, I predict that Michigan will, in ten years from this time, turn out a greater surplus than any other state in the union does at present.

Wheat and Wool are to be the great staples of the state; we have done with producing pork, beef and coarse grain, at a loss of 50 or 75 per cent. on first cost, as at present prices.

While on this subject, I would ask what is the cause of the present low prices of these articles, if it is not on account of over-production, or too great a surplus and no foreign market, at a price that will pay us the first cost. Now suppose that the tariff is increased on wools as well as woolen, the prices of wool would be raised, and all the farmers in the Union turn their attention (as they undoubtedly would) to the production of that article, how long would it be before the market would be glutted, (the same as with pork at present)? Would not prices then be brought back again, if perhaps not below the present standard? Would you not then have just cause to call on Government for an additional tariff? more especially as they had stimulated you to invest your whole capital in the production of that article, at high prices, and would they not be bound again to throw around you the mantle of protection, by way of a bounty or otherwise to be again followed by over production, fall of prices, and then an other call for increase of protection?

I have been told that the manufacturers purchase wool in a foreign market say at 21 cents per pound, and then fill it with 2 lbs. of sand to one of wool, or saturate it with some substance which costs nothing and is easily separated or cleaned, until it brings the first cost of the wool down to 8 cents per pound, or below, and then it is to be admitted into our country free of duty. On its arrival here they open the bales and shake out the sand, or cleanse it in some other, and they then have a fine article free of duty, worth 50 cents per pound in our market.

I do not pretend positively to vouch for the truth of the charge, although to me it seems not improbable.

But the cry is, give us high prices or we perish. This I admit is a debatable question, and one that ought to be well understood by the great mass of producers; but to my mind, a system of high prices is unfavorable to the prosperity of this great nation.

I wish to be understood, so here I assert, that a general system of low prices is better for the laborer, the farmer, the mechanic, and manufacturer, (that is, that an absolute specie standard is better than a fictitious paper credit,) and that it is better that improved farms should be worth twenty dollars per acre, and laborers dollars per month, and wheat six or seven shillings per bushel, and manufactured goods and every thing else in proportion; than it is to have all things twice or three times higher, because at the low scale of prices we might export a surplus to foreign countries, and at the higher rates, foreign countries would undersell us.

In short, special legislation of any kind, that has a tendency to raise up prices and establish a fictitious value upon property, whether by a protective tariff as a general policy, or a credit currency or any other monopoly, fraud or fiction, is decidedly injurious to the productive classes, and the best interests of this country. I am satisfied that the tendency of this nation is to purchase all the goods we are able to pay for under any circumstances, and when we imagine ourselves wealthy from either of the above causes, we purchase more goods than we are able to pay for, and instead of getting rich, we become miserably poor by the operation.

The high priced, high tariff advocates will now ask; would you reduce us to the condition of the Russian serf, or the English weaver, and in what is our condition better than theirs, unless we obtain higher prices for labor than they do?

I answer that labor is best paid when it will obtain the greatest amount of the necessities or luxuries of life for a given service performed; that it is the relative and not the nominal prices of labor and necessities that determines when labor receives a just reward; and you cannot reduce the producers of America to the condition of the operatives of Manchester and Birmingham, until our Government under the specious pretence of "protecting our industry," taxes us enormously, by way of a Tariff, on all the imports we eat, drink or wear, and allows a bounty on a portion of our exports to some favored class; taxes us for the glass in our windows, and for every thing under Heaven, and then in addition, takes one tenth of all the products for the support of one established church.

In short, when our Government adopts the whole system of British "protection," of which ours is a faithful copy, all except the "sliding scale," then and not till then, will the producers of America be brought to the same condition of the producers of England, the operatives of Manchester and Birmingham, and then we may perhaps boast of a splendid government and sing America "rules the waves," and dictate to the nations of the earth, with death and starvation staring us in the face to the extent of 20 thousand human beings annually.

J. S. DUTTON.

Monroe, Mich., 1842

AGRICULTURE OF ONTARIO COUNTY.

The present condition of agriculture in this county generally, as well as in this immediate portion of it, may be called good. The soil of Ontario is rich, but in different sections it presents every variety of loamy, clayey, sandy, and the various degrees of admixture of these.

The aspect of the country is agreeably undulating and picturesque. The principal product of the country, since its first settlement, has been wheat. The coarser grains are cultivated, but mostly for domestic consumption.

Wool has become within twenty years, an important product of our farms. The town of Richmond had, at the recent census, about 25,000 sheep, chiefly Merino and Saxon, and these mixed upon the common stock. Some, but not much attention has been paid to the Bakewell, South Down and larger breeds of English sheep. Our sheep husbandry would doubtless be improved by increased attention to root-cultures, beets, running, &c. Our wheat is sold to the merchant millers of the neighborhood, whence the flour is mostly sent, by the way of the Erie canal to New York and Boston. A portion of it, however, finds its way to the Canada market.

Our wool is generally sold at home, to purchasers for the eastern manufacturers.

Of cattle for milkers and beef, the short horned Durham is the favorite breed. For working oxen, the Devonshire is still the best. Of swine, the Berkshire is, at present, the favorite. Much pork, since the temperance cause has been in the ascendant, has been fattened on apples. For a number of years, I have fed my hogs but about a fortnight on Indian corn, after taking them from the orchard; and have thus made excellent and profitable pork. Good horses are raised in this county; but the present race are an admixture of almost all varieties of breeds.

The different kinds of hickories, black walnut, butternut, elms, maples and beech are the prevalent timber of this neighborhood.

The value of farms may be said to range from \$35 to \$50 the acre, according to the situation, quality of soil, buildings, &c. &c. Occasionally, farms are sold at higher prices.

Clover, timothy and redtop, are the grasses most cultivated and most profitable for pastures and meadows.

To the question—"what agricultural changes are requisite to advance the prosperity of the country?" it may be answered, the extended introduction of the silk culture would probably be one of these changes.

Our farmers are industrious, enterprising and tractable; ready to adopt, and give fair trial to any improvement in the science of agriculture, to test new implements and machinery, and need nothing to advance their prosperity, but wholesome and steady laws of protection to American industry.

[Trans. N. Y. State Ag. Soc.

Rust in Wheat.

We extract the following from the American Farmer of recent date. It certainly deserves attention, and we commend it to the consideration of intelligent and observing persons. The advice in regard to early cutting is to be received with some caution. We approve of early cutting, but in one case we know that we cut too early; and therefore feel that this danger is to be guarded against. We remarked on the error committed by many farmers in this matter in our last number.—Ed.

Hence, then, we infer, that *pestilence*, or over-fellness in the supply of any, arising either out of the peculiarly favorable condition of the atmosphere, whose phenomena we have described, or an over rich soil is the cause of the disease, and in this we are borne out by two eminent agriculturists, whose essays we have

already published, but shall not extract a sentence or two from each, by way of strengthening our position.

Wm. M. Peyton, Esq., after enumerating several assigned causes, says:

"But if on the contrary, it results from *Plithora*, induced by excessive vegetation, then I am fearful it can only be lost remedy."

"That the last is the true character of the disease I am convinced, though I express the opinion with some diffidence, as I know it is opposed to the views of many agricultural writers of distinguished reputation."

"I have heretofore supposed that the exudation proceeded from the bursting of the minute surface vessels, whose rupture not being visible to the naked eye, had discredited the theory which taught the existence of what could not be seen. But in a conversation a few days since with a sensible and observing farmer of a neighboring county, he told me that the ruptures were distinctly visible, when the rust was removed with pointed tools. On the same day he illustrated the correctness of his statement by producing several stalks of rusted wheat, upon which longitudinal ruptures were very distinct under every blotch of rust examined."

C. G. Green, Esq., the President of the New Jersey Agricultural Society, in his late report, gives the following cases, tending to the same point as the one given above:

"One of our farmers had an extraordinary piece of wheat, which he thought out of danger, it was so nearly ripe. On a very hot day, between the hours of one and three o'clock, there came a small cloud over, which completely drenched the field of wheat. A deadlike stillness succeeded; the cloud passed away; the sun shone extensively hot. The owner in this state of the case, went to examine the wheat, as it was much pressed down by the shower; he immediately observed a continual ticking, or snapping noise in every direction in the field. The straw was fine and bright, but upon examination he perceived it bursting in short slits of a fourth of an inch long, and the sap exuding in thousands of places. A day or two after, the whole field was darkened with rust and the wheat of little value. It does not appear that these circumstances take place while the wheat is growing, but only at the critical state of ripening."

On my neighbor White's farm some years since, was one of the heaviest pieces of wheat straw I ever saw, remarkably fine, and nearly ripe. I had also a good piece advancing fast to maturity; on a clear morning, a small cloud of fog arose from the meadow and gradually covered the two fields, but was not a general fog; being very still, it remained hovering over the fields until the hot sun dissipated the vapor. Being acquainted with the above case, I was alarmed for the wheat and watched over it with deep interest. When the sun had somewhat dried the straw, and warmed it, the straw began to burst with a continual ticking noise, the sap exuding at all these little splits. In a day or two the fields were black with rust except some small spots, which are worthy of notice. An acre or two of mine was so nearly ripe that the wheat was tolerably good, and the rust on the spots of a reddish brown. In Mr. White's field there were some trees which kept the intense heat of the sun from the straw; there was tolerable wheat, also. The rest of the fields would scarcely pay for gathering and thrashing."

A question of importance arose in these two cases. Was this injury a fungus, the very fine seeds of which float about and attach themselves to the straw, as some of our learned agricultural writers tell us, or is it the sap of the straw that ran out and was dried on the straw, and was reddish or black according to its state of ripeness or fulness of sap?

Your committee are decidedly of the opinion that the sap being lost at this critical time of ripening is the true cause of the shrinking of the grain."

It must, we think, strike the reader very obviously, that this rust is not occasioned by parasitical plants, or fungus; that if the discolored matter on the external surface of the wheat plants, be or present the appearance of, parasitical plants, that it is produced by the rupture of the overcharged vessels of the plants, and is in fact oxidized sap which had thus escaped and formed a species of paste or jelly on the outside. We do not pretend to deny that in the interval between the exudation and the drying of the sap, that living fungus bodies had not taken up their abode therein, for such is one of the consequences of putrefaction—it is sufficient for us, to endeavor to show that the bursting of the vessels of the wheat plant, is the cause of the rust.

It may now be asked, are there any preventive

measures to be used? We answer that we do not know any—and among them these:

1. *Deep ploughing.* By this, the roots will be permitted to extend themselves so deep as to be without the immediate range of sudden atmospheric action—all fermentable manure, applied to previous crops, will also be deposited too deep to do harm from similar causes.

2. Application of saline manures, as lime, marl, plaster, salt, &c., and the avoidance of all use of any strong manures, which are liable to active fermentation.

3. Any soil whereon wheat is grown—if not naturally dry, to be made so by draining.

4. Increased quantity of seed to be sown.

5. Earlier sowing, so as to enable the wheat to ripen at least two weeks earlier than at present, and thus avoid the evil effects of the unfavorable weather which prevails at the particular period on which its ripening is now chosen.

6. Sowing an earlier variety of wheat, with the objects above stated in view.

7. Raking the ground immediately after ploughing in the seed in the fall, and once in the spring.

Thus far of preventive means, now a word or two about remedial ones, to rid the above land to keep off the rust.

After using the precautionary means recommended above, your wheat should be removed, cut it as soon as the grains may be thoroughly formed; never mind if they should be still in the milk, they will get nourishment enough from the stalk to ripen them. By cutting before the straw is heavily destroyed, you not only save the straw, but will get more grain, and better flour than if you wait for it to mature standing in the field in rusted stalks.

SOILS.

We extract the following simple account of soils from a recent Farmers' Journal, Eng.

Mr. W. M. Chatterley delivered his eleventh lecture at Hovey Bower, near Runcorn, on Monday, October 3d, on Soils.

Soils may readily be supposed to partake of the geological character of the formation on which they rest, and such in truth is the case. The time to which the present lectures were limited would not permit the subject of geology, even the geology of Britain, to be discussed; it would, therefore, be sufficient for the purpose to state that the three most generally diffused minerals, viz., clay, limestone and sand, were all necessary constituents of a fertile soil, but that the proportions in which they occurred in different soils varied, and that too in accordance with the geological character of the subsoil. As either clay, lime or sand was the predominant ingredient, soils were classified accordingly into aluminous, calcareous or siliceous soils. Either of these earths alone form a barren soil; sand, as each may be in greater proportion, it imparts to the soil its peculiar character; stiffness, attraction and retention of moisture, hardening into a brick-like consistency, and cracking during dry weather, the characteristics of soils on the clay; great friability, speedy filtration of water, and general dryness, are the opposite characteristics of sandy soils, plain indicating their mutual admixture as a means of remedying some of the defects of either; the rubby or marly character of calcareous soils, allows of speedy filtration, and causes too great dryness, indicating the benefits to be derived from the addition of either clay or sand. An excess of sand is much less injurious than an excess of clay; indeed, all the most fertile soils contain a larger proportion of sand than any other mineral ingredient. The different natural mixtures of these earths have given rise to the different terms by which peculiar soils are distinguished, as loams where clay and sand form the chief constituents, or marls, where clay and limestone meet and abound. The purest clay soils, however, do not contain less than 60 per cent. of silica, while many siliceous soils contain from 90 to 95 per cent. of sand.

Vegetable matter in soils is also necessary to their fertility; and the varying quantity of this material, from about 10, as in garden mould, to 70 per cent., as in peats, gives to these soils the characteristic whence they derive their names.

But, as has been said before, neither the pure forms of clay, sand, or limestone alone form fertile soils, but the contrary; so it is to a proper admixture of these that we must look for the fittest condition of a soil. It generally happens most happily that sand, clay, or lime are found within reach of one another, and ready to be used mutually for the amelioration of the soils, in which they mutually predominate; and it should be remembered that such amendment is permanent.

The other constituents of soils, which are not so abundant, in order that they should retain their fertility, they must constantly contain the alkalies, potash and soda, and the alkaline earths, magnesia, with the sulphuric, muriatic, and phosphoric acids, the peroxides of iron and manganese—these substances serving as the food of plants, while the sand, clay, and limestone form the body of the soil, amongst the particles of which the roots penetrate, and support the plants by their mechanical action.

The chemical properties, however, of the three chief constituents of soils should be attentively considered also, as tending to elucidate many anomalous instances of unproductiveness in particular soils. The attraction of clay for water renders it highly useful in siliceous soils, which have no such property; its adhesiveness tends to bind together the loose falling particles of the sand; while these very properties, when in excess, tend to render the soil unfruitful, and are then to be remedied by mixture with sand or lime, to increase the friability and filtration, and thus, in either case, to permit the passage of a rapid water amongst the particles in the soil in such a manner as to preserve a due but not excessive degree of moisture in the soil, so that it is neither retained too long, nor removed too soon. These three, the chief constituents of the soil, though they may either of them be requisite in a slight degree as the food of plants, are not to be considered in this light merely, but rather as having for their chief use the mechanical duty of affording support for the roots of crops.

The state of chemical combination, in which the various ingredients of the soil are found, also materially influences its fertility, though such combination should differ somewhat for particular crops; for instance, wheat requires that a portion of a silica should be in union with potash, and for clover, that sulphur should exist in the soil in the condition of a soluble sulphate; should the soil, however, contain sulphate of the protoxide of iron, as is the case sometimes in the London clay land, in peat soils, it is altogether injurious, and should immediately be converted into peroxide by exposure to the atmosphere, by frequent and deep ploughing, harrowing, and disintegrating.

Much practical action, as to the mechanical action of the various farming operations, and on the chemical constituents of soils, was added, but it is to the conclusion that the farmer must endeavor to know the quality of the minor, but still, deficiencies of his soil, and for the easiest and cheapest mode of remedying them. There was no reason why a farmer should not be acquainted with chemistry; but if not so himself, there were many of the latter class who now were turning their attention to agriculture as connected with the science, and with whom there would be no difficulty for the farmer to put himself in communication.

The proportions of the chief constituents of soil, best suited for all crops, were then shown to be from 50 to 70 per cent. of silica, from 20 to 40 of alumina, and from 10 to 50 of calcareous matter.

The mode of arriving at a proximate determination of the relative qualities of each of them was then shown. The quantity of moisture was found by drying a given weight in an oven, and finding the loss of weight; the quantity of vegetable matter, by heating a given weight of the dried soil to redness, and retarding the loss; the quantity of soluble salts, by treating a given weight with water, filtering and evaporating the filtered liquor to dryness; the quantity of carbonic acid, by throwing a given weight of dry soil into a given weight of diluted hydrochloric acid, and estimating the loss of weight after effervescence had ceased; the quantity of lime, by filtering the solution in hydrochloric acid thus made, and precipitating by oxalate of ammonia; the quantity of clay and sand, by repeatedly washing a given weight of the soil with water, and pouring off after allowing it to settle for a minute or two until the water was entirely separated, then drying and weighing a bowl.

TOBACCO.—So sensible is every brute creature of the poisonous and deleterious quality of this plant, that not one of all the various tribes of beasts, birds, or reptiles, has ever been known to taste of it. It has been reserved to man alone to make of this poisonous plant an article of daily necessity for the gratification of his depraved appetite.—*The Mirror.*

Sound and Light.—Sir John Herschel says that thunder can scarcely be heard more than 20 or 30 miles from the flash, but that lightning may be seen at a distance of 200 miles.

From the transactions of the New York State Agricultural Society.

AGRICULTURE OF MADISON COUNTY.

Madison county embraces fourteen towns, and contains 5-2 square miles, or 327,000 acres of land, and 40,032 inhabitants.

The surface of this county is much diversified. The elevated ridge which separates the waters of the northern lakes from those of the Susquehanna river, passing through the southern part, renders it, with the middle, more or less hilly and uneven. These hills, however, are not so steep as to unfit for cultivation, and the valleys are extensive and very fertile. The northern section of the county is generally more level.

The county is well watered by streams in almost every part, and in the northern towns of Sullivan and Lenox large masses of gypsum and water limestone, with some iron ore, are found. Common limestone is scattered in abundance over all the middle and northern towns.

The Erie canal and the Utica and Syracuse railroad pass through the upper, and the Chenango canal intersects the lower part of the county, affording fine outlets for all her products.

Soil.—The fertility of the soil is very great; in deed it is supposed, in that particular, to be surpassed by but few counties of the State; and there is but little land within its boundaries that is not well adapted to cultivation.

The northern parts are mostly of a limestone soil, except the low bottoms, which are sandy, and the middle and southern sections may be designated as of a clay loam, based upon shale, or slate rock. It is a fact worthy of remark, that this county seldom suffers from want of rain.

Productions.—The northern part of the county being generally level, is admirably adapted to the growth of wheat and corn.

The centre and more elevated parts produce large quantities of wheat, barley, oats, corn and hops, and the southern parts grow hops, barley, oats, and potatoes, in which latter crop they excel the other parts of the county, both in quantity and quality.

The soil is almost every where natural for grass, the crops averaging from one and a half to two tons per acre, of a superior quality, mostly upland. And this, with but a small outlay, might be easily increased to from 2½ to 3 tons.

The wheat lands, under good management, give from 20 to 25 bushels per acre; barley 35 to 50; and oats from 40 to 70 bushels; in some cases coming up even to 100 bushels per acre. Large quantities of peas are also grown.

The production will appear more accurately by reference to the returns of the census of 1-40, in which year Madison county was shown to have raised

200,242 bushels of wheat,
135,625 do barley,
342,257 do oats,
171,204 do corn,
678,619 do potatoes,
374,021 pounds of wool,
117,370 do hops,
215,619 do sugar,
65,749 tons hay.

Butter and cheese to the amount of \$193,670. Which, together, at the low prices of 1840, yield the amount of \$1,379,345.

Markets.—The farmers of this county usually find a market for their produce with the merchants of the villages, who in turn send it to the city of New York. The cattle fattened for market are driven to Albany and New York city; and those for grazing are sent to Philadelphia, and the farms along the North river.

Cultivation.—Attention to agriculture has been gradually increasing in this county; there is, how-

ever, yet much room for improvement. But little importance is attached to regular systems or rotation of crops. Wheat is raised after summer fallow with two or three ploughings, and the same crops are frequently allowed to succeed each other.

The manure from stables is put generally upon the land, and plaster is also applied to winter grain and grass; but as yet very little value is attached to manure, and no methods are taken to increase it. Lime is seldom employed, although it is admirably adapted to the soil, and composts are unknown. There appears, however, to be a general awakening to the importance of the subject.

Drainage, particularly that under ground, has been partially attempted, but not to any extent, though the soil in many parts would be much improved thereby.

Of grass seeds, clover, timothy and redtop, are sown, the latter on interval lands liable to be flooded. Clover is seldom sowed alone, being usually mixed with timothy.

Top dressing grass lands is occasionally practised, and with great benefit.

The profitable practice of cutting or chopping straw for feeding stock may be said to be hardly known. Straw is generally stacked out, and cattle allowed to take what they want of it. It is also used for littering horses, but there are instances where it is hauled away from the buildings and burnt to get rid of it!

The cast iron plough of various constructions, with cultivators, harrows of different kinds, horse rakes, rollers, &c. &c. are in use, but few of the new improvements in agricultural implements are found here, unless perhaps occasionally a mowing machine.

Animals.—The horses of this county are very good, strong, of good size, well made and admirably adapted to all farming purposes; but they cannot be designated as of any particular strain or blood.

The breed of neat cattle is also excellent; cows on fresh summer feed, giving, in some instances, 25 quarts of milk per day, and generally from 15 to 20. Blooded cattle have not been introduced to any extent as yet. This county, however, at the late fair of the State Agricultural Society at Syracuse, was among the successful competitors for premiums in that line. Deceivers from the east say that they find about the best of cattle in this county and neighborhood.

In swine but little pains have been taken. The pork of this county is, however, very good, and in many instances Berkshire hogs have been successfully crossed with the (so called) native breed.

The sheep of the county are generally Merino and Saxony. Formerly large flocks of tall blooded animals of these breeds were found throughout the county, but now they are more mixed; attention not having been paid to keeping them separate.

Except by some few of the best farmers, no pains are taken to shelter sheep in winter. They are kept, usually in flocks of from 70 to 160, and from 300 to 1000 on a farm. The southern part of the county has been much afflicted with the rot or "foul air," which breaking out in large flocks where the frost at season could not be given as to smaller ones, did much damage. It is, however, now rather diminishing. As to the cause, farmers here, as elsewhere do not agree, each one having a theory of his own.

By the census before referred to, it appears there were in the county in 1840,

9,358 horses and mules,
42,191 neat cattle,
186,616 sheep,
39,657 swine.

Value of Land.—Land in this county may be said to rise in value from \$10 to \$100 per acre, generally increasing from \$20 to \$50; and the size of farms to

range from 50 to 600 acres; for the most part comprising from 100 to 150 acres each.

Timber.—The prevailing timber of the northern part of the county is maple, beech, oak and pine; and of the middle and southern sections, maple, beech, hemlock and bass. There is, however, throughout, a great variety, comprising walnut or hickory, ash, birch, elm, spruce, white cedar, chestnut, fir, butternut, poplar, balsam, whiteoak and sycamore.

In conclusion: with regard to the "changes necessary to advance the agricultural prosperity of the county," it may be said, that the general diffusion of agricultural intelligence and disposition to seek for and take advantage of the improvements adopted by others, is all that is wanting to place this county in the rank which the bounty of nature has intended it to assume.

For this purpose no better means can be devised than attention to the different agricultural periodicals now published; which, from the extreme low price of subscription, are available to every farmer however small his means. The Genesee Farmer or the Cultivator should be in the hands of every one. These contain the results of the experience of our neighbors, and affording the means for the general interchange of ideas, cannot be too highly prized.

The Agricultural Society of the county, also, which has been but lately established, will, it is hoped, do much towards its advancement.

We add a second account of the Agriculture of Madison County from an experienced hand.

The county of Madison contains a diversity of soils, and may be said to vary much in its climate; as the northern part, between the Erie canal and the Oneida lake, is in general only between 350 and 400 feet above the level of the tide waters, while the central and southerly, and southwesterly parts rise in ranges of hills to the height of from 1600 to 1800 feet above the level of tide waters. There is always a marked difference in the time of the ripening of grains and the general maturing of crops between the lower and more elevated parts of the county—always being earlier in the northern and lowest part. The lands from the Oneida lake south to the Erie canal are level, the lake being only about 45 feet lower than the long or Utica level of the canal, and are generally a rich alluvial soil, some districts of which are well adapted to the culture of the different kinds of grains, and all, or most of it, is considered a great grass growing district. Immediately south of the Erie canal, generally the land commences to rise until it terminates in the elevations before mentioned. A belt of land south of the Erie canal for some distance as it rises in the vicinity of the lime and gypsum formations, passing through the towns of Sullivan, Lenox and Stockbridge, is undoubtedly the best wheat district in the county, and also excellent for all other grain crops. There is another district of land, different from the lands of the county generally, and may be termed table land, and is of a general elevation of 800 feet above the Erie canal at Utica. This section of land commences in the east and northerly part of the town of Madison, passing west and south-westerly quite through the town into the easterly part of the town of Eaton; thence more southerly through the west and southwest part of Madison, east and southeast parts of Eaton, west part of Hamilton and east part of Lebanon, to the south line of the county, and passes into the county of Chenango from Hamilton, bounding the northern entrance of the Chenango valley. All of this district of land (or principally) is a very deep and porous loam and gravel soil; some parts sandy loam and gravel, and is a strong and fertile soil, and is peculiarly adapted to Indian corn, which has

matured on this land in the month of May.

This district of land is also adapted to every other of the straw grains cultivated in our country, and invariably produces heavy crops, and is a natural grain growing district. Most of the town of Cazenovia is also adapted to the culture of grain.

There is in fact but little of the highest lands in the county but what produce good crops of spring wheat, barley and oats, and Indian corn matures on it in favorable seasons. Barley is shipped to the Albany market to some extent, but the surplus grain generally finds a market at the extensive distilleries in this and the adjacent county of Oneida. This county is susceptible of producing an amount of grain for export vastly larger than it does. Notwithstanding, as a whole, it is a better grazing than a grain growing county. It is probable that there will always be sufficient of the grains produced in the county for home consumption, and a considerable surplus for market, and particularly of the coarse grains. When the county was new, winter wheat was raised in abundance, even on the hill land, and on the first summer following of pasture lands, heavy crops of winter wheat were produced, and were not hurt out by frost. No one then doubted but that it would always be a wheat country, and to a considerable extent it might still be, but for the action of the frost on the hill lands, heaving out the roots of winter wheat. There is but little hill land that has been pastured a few years and then summer fallowed, but has strength of soil sufficient to produce a heavy crop of winter wheat, and have it fill well when the action of the frost is prevented, which has been sufficiently proved; but spring wheat on the hill lands generally is cultivated, on account of the precariousness of winter wheat; and the variety which obtains most favor is the Italian.

It has been abundantly proved, that spring wheat, barley, and oats, can be advantageously produced on our uplands, on greenward turned over. But as a whole, the true interest and most permanent wealth of the inhabitants of the county, lies in the cultivation of the grasses, on which the greater portion of the farmers of many sections of the county, have for many years bestowed their chief attention, and in rearing neat stock for store cattle, fattening, and for the dairy, and numerous flocks of fine woolled, and other grades of sheep; which has been a lucrative business, having made many farmers wealthy, and all those in a thriving condition. The soil of the hill lands of the county, differs much from the table lands and the valleys, being generally free from gravel, and is generally composed of a rich loam and vegetable matter. The loam, in many places, is of a dark or chocolate color, in other places of a lighter color, inclining to yellow.

The native growth of timber is maple, beech, white ash, white and red elm, hatternut, cherry, some birch, in many places considerable hemlock, batternut hickory, and in the northern and northwestern parts of the county white and black oak, and hickory; and in swamps, white pine, cedar, and black ash. There are some upland pine lands, but they are not extensive, and the timber has principally been converted into buildings. The neatstock of the county is short of the native breeds; there are not many Short Horn Durhams, though some. There is yearly a considerable number of neat cattle fattened for market. The principal article of food in fattening them, is the potato; but Indian meal, barley and oat meal, is also used as feed with the potato, and also oil cake. Pork is also fattened extensively on potatoes boiled and mixed with barley, and oat-meal, peas, and some Indian corn is fed towards the close of the fattening, but is not extensively fed. Good and heavy pork is made by the above mode of feeding. Those who keep a dairy, fatten hogs on the refuse of the dairy.

Swine consist of various breeds, and crosses, and are much improved since the first settlement of the county, and are still improving. Berkshire, and crosses from them, are becoming common, and are in high repute.

Of sheep the Merino and Saxony have prevailed, with every imaginable grade, by crosses on the native breeds.

As a root crop, potatoes prevail vastly over all others, and are extensively cultivated both for fattening domestic animals and for feeding store cattle; and are abundantly produced, or can be, on most soils in the county. The ruta baga has been cultivated by some, but has not obtained favor with the farmers generally. Carrots are cultivated to a limited extent by some, and fed to milk cows and other stock, and are held in high repute. Hops have been extensively cultivated from an early day in this county, and yet continue to be, which has been a source of considerable wealth to those engaged in that culture.

The ploughs in use are the cast iron, of various patterns, no one prevailing exclusively. Double or single harrows, are much used of late years, and are considered a great improvement in that article. Cultivators of several models are used among corn, and are considered an improvement by many, over ploughing among it, at the time of hoeing.

Of grasses for mow-lay, timothy or herds grass, is mostly cultivated, clover mixed with it to some extent. On wet or swampy lands, red top or foul meadow. The principal grasses cultivated in the county for meadow and pasture, are red and white clover, herds grass or timothy, red top and foul meadow. Spens or June grass, grows spontaneously without cultivation. Some orchard grass or *Dactylis glomerata*, is cultivated by some, and produces an excellent hay, and an abundant growth of feed for pasture, and for that purpose is most valuable, starting earlier in the spring, and after being mowed or fed off, enduring the drought better, and yielding feed later in the fall than any other, and its roots never winter killing, and is easily subdued. Its culture should be extended, and particularly for pasturage. The greater part of the county being hilly with numerous valleys of rich land, the hills abounding with springs, which water the valleys, peculiarly adapts it for a grazing and stock growing county; and all the best grain districts will also produce good meadows and pasturage. The fat cattle and sheep, pork, butter, cheese and lard, are principally sent to, or purchased for the New York market.

Store cattle and swine are either sent to, or purchased for the different eastern markets. The aggregate annual value of grain, store and fat cattle, pork, lard, and store swine, store sheep and wool, hops, and the products of the dairy, that are sold at the different markets, I have not the statistics of before me, but which I think amounts to nearly \$2,000,000.

Wool is one of the principal staples, some of which finds a market at the manufactories of this and the adjacent counties; but it is mostly purchased by wool staplers for the manufactories in the New England States.

In addition to farmyard manures, gypsum is used to a considerable extent as a fertilizer, particularly on pasture and meadow lands.

In regard to rotation of crops, the practice that most prevails, and particularly on the gravel table lands, is, to spread the stable and barn-yard manures on the greenward of pasture or meadow lands, carefully turn it under, pass over a roller, drag with a light harrow, and plant Indian corn, dress the crop with a cultivator, and hoe twice; and it is not uncommon to obtain a yield of from sixty to seventy bushels per acre. The succeeding spring this land is sown with

barley, and it produces a heavy crop; the stubble is then turned under and sown to winter wheat, and seeded to grass; the wheat yielding generally a heavy crop, and the land left in a better condition than before. The same rotation prevails to some extent on the up or hill lands, except sowing spring grain, generally after barley; the crop of winter wheat being more precarious on such land.

In regard to the culture of silk, a number have commenced the business on a small scale, and their experiments have generally been satisfactory, demonstrating that it can be made a lucrative employment for females, and the labor of children. In fact, there cannot be for females so lucrative a domestic employment, to those who wish to be industrious, as the culture of silk, and of manufacturing the raw material into sewing silk and various articles of dress, both for use and ornament, for which the ingenuity of the fair of our country are distinguished. But the natives must finish the planation of mulberry trees.

The Morus Oregona, or Oregon Mulberry, was introduced into this place by me, some five years ago, or five years next spring. They prove to be hardier than any other kind or variety with which I am acquainted, and I have ten different kinds and varieties. My new plant has endured the rigors of our severe winters, without injury, where the Italian, or Morus alba, standing beside them, would be killed, both if the branches and the main stem. I have them growing at an elevation of about 1300 feet above the level of the tide waters at Albany, and nearly 43° N. latitude, and flourish well. The leaf of this new plant is larger than the Multicaulis usually is, and is much thicker and more heavy, being a more fleshy leaf than any other of the mulberry species known to me, with but very little woody fibre in the leaf; and it contains much more milk juice, and less of water, than any kind known to me. I have fed the leaf of this new plant to silk worms, four seasons, and in all cases my worms did better, fed with this leaf; were more healthy, and made better cocoons, than those fed on the other kinds; and in all cases, produced a finer and more flexible filament, and of a richer and more brilliant lustre than I have ever seen on any silk other than this, either foreign or domestic; and the silk has been so pronounced, by hundreds of the best judges of the article. This tree will certainly be an acquisition to silk culturists, particularly in the northern States, as the culture of silk progresses, and the merits of this tree becomes known.

In regard to the value of lands, there is but little improved or partly improved, in the remotest situations but will sell for \$20 per acre; and better lands, and more favorably situated, are valued from \$25 to \$35 per acre; while the best situations, of farms, both in regard to the roughness, soil and buildings, are valued at from \$40 to \$60 per acre. Farms have been sold as high as \$60 per acre; but the average value of land in the county, I think, would not exceed \$25 per acre.

The Names of Plants and Flowers.

It is proposed to substitute plain English for the dog latin terms at present applied to plants and flowers—an attention which would, we think, be advantageous, and meet with general approval. Cable, whom nothing was too minute to escape, has admirably ridiculed this botanical pedantry:

“High-sounding words our worthy gardener gets,
And at his club to wondering swains repeats;
He there of Rhina and Rhododendron speaks,
And Allium calls his Onions and his Leeks.
Nor weeds are new; from whence arose the weed,
Scree plants, fair herbs, and curious flowers proceed;
Where cuckoo pints and Dandelions sprang,
(Grass names had they our plainer sara among.)
There Aronis, the Leon-tortions we view,
And Artemisia grows where Wormwood grew.”

THE NEW GENESEE FARMER
AND GARDENERS' JOURNAL.

Vol. IV, for 1843.

Published by C. F. CROSMAN and E. SHEPARD, Rochester. Sixteen pages monthly, enlarged and improved: price \$1 per year.

The character of the Genesee Farmer, both old and new, has been well known, and its ability and usefulness universally applauded. Published in one of the best farming districts in the world, and in one of the finest and busiest cities of the growing west, the very home of active industry and intelligence, where information and mechanical talent of the highest order are concentrated. No pains will be spared to make it all that such a paper should be.

Under present arrangements, Mr. Colman is expected to continue in the editorial department for the first third of the year; and whenever he retires from its supervision, it will pass into able and competent hands, who will do justice to the paper and its subscribers. Mr. Colman contemplates an agricultural Tour in Europe, and will be a regular correspondent of the paper through the year.

Mr. Bateham, as traveling agent and correspondent, designs to spend most of his time among the farmers, observing their condition, and operations, and his contributions will be interesting and practical. The numerous and able correspondents of the N. G. Farmer, it is expected, will continue their valuable contributions. With these arrangements, the proprietors feel assured that the long tried friends of the Genesee Farmer will not desert the paper; but will use their influence to extend its circulation and usefulness. If each subscriber would make it an object to procure one other, he would render an essential public benefit. The correspondence being extended throughout the country, the paper will embrace the husbandry of the whole: of New England, the Canadas, the Middle, the Southern and Western States; and it will communicate the fullest intelligence of the progress of agriculture in the old world. Being connected with an extensive Agricultural Establishment for seeds and implements, under the management of one of the Publishers, it will furnish information of all improvements in these departments. The proprietors will use their utmost endeavors to concentrate the best talent in its management; to have its mechanical execution and appearance greatly improved, and to render it entirely worthy of the patronage of practical and intelligent farmers.

SIX COPIES will be furnished for \$5. THIRTEEN COPIES for \$10. ON TWENTY COPIES and over, a discount of thirty per cent will be made. Bills of all specie paying banks will be taken at par.

Editors who will give this prospectus one or more insertions, will be entitled to receive one volume of the paper without an exchange.

POSTMASTERS are permitted by law to remit money free of postage. The friends of agriculture are respectfully requested to assist in obtaining subscribers. Back numbers or volumes can be furnished.

Communications on business or for the paper, may be addressed to CROSMAN & SHEPARD, Rochester.

Wayne County Agricultural Society.

From some strange circumstances, the following errors occurred in the account of this society in our last number, some of which wholly alter the meaning:—

For 'eight months' read October.

10th line, for 'difference' read 'deficiency'.

43d line, for 'half blood' read 'half-bred'.

52d line, for 'and' read 'are'.

64th line, for 'in' read 'r'.

Last line, for 'J. T.' read 'N. B.'.

European Agricultural Tour and Survey.

Several gentlemen, interested in the advancement of agricultural science and improvement and of rural education, have proposed to Mr. Henry Colman, late Commissioner of Agricultural Survey of Massachusetts, to visit Europe for these objects. The plan is him to spend a year in England in the examination of the Husbandry and Rural Economy of that country, and a year on the Continent in the examination of French, Flemish, Swiss and German Husbandry, and especially the Agricultural or Manual labor Schools and the experimental farms.

It is thought that such an examination, as yet never undertaken by an American, might, if well conducted, essentially conduce to the advancement of agricultural knowledge and improvement in this country, and especially serve the cause of moral and practical education, which is now exciting great interest throughout the United States. The general plan of the Survey will conform to Mr. Colman's Survey of the Agriculture of Massachusetts.

It is proposed to publish his reports in successive Nos. The first number is expected to appear by the first of January, 1844, and summer is preferable. The rest of the numbers will follow in convenient succession at intervals of two or three months.

The whole work will be comprised in eight, or at most ten, numbers of at least 100 pages each, handsomely printed in an octavo form, stitched and covered, and embellished with necessary and useful drawings and engravings, title pages and index.

The cost will be fifty cents each number to subscribers. Gentlemen who subscribe are understood as subscribing for the whole work.

As the enterprise involves of necessity a large expense, it is expected that one dollar per copy will be paid on subscribing; or otherwise, one dollar on the delivery of the first number; one on the delivery of the second number; one on the delivery of the fifth number; one on the delivery of the seventh number; and one on the delivery of the ninth number, should the work be extended to ten numbers.

Mr. Colman will leave for Europe as soon as the subscription will warrant the undertaking.

An early return is respectfully requested of gentlemen to whom this is sent, addressed to Henry Colman, Rochester, N. Y., to Little & Brown, Boston, Mass., to Charles S. Davis & Co., No. 252, Broadway, New York; or to Luther Tucker, Cultivator Office, Albany, N. Y.

October 4, 1842.

To Subscribers and Correspondents.

The December number of the Genesee Farmer has been delayed until this time, on account of the new arrangements made necessary by a change of proprietorship, and Mr. Colman's preparations for his Foreign Tour. Every effort will be made hereafter to ensure punctuality of publication and delivery.

Several cases have within a few months come to our knowledge of a failure of the receipt of the paper on the part of our subscribers. Much of the blame, we fear, to our great regret, belongs to ourselves; but the cause, which we have suspected, has been discovered; and we trust there will be no more reason for complaint.

The Editor was anxious to mention particularly, in this number the receipt of many valuable communications. He has not room to do this; but they have been received with great respect; and his friends may be assured shall be duly acknowledged.

Monroe County—Notice.

The annual meeting of the Monroe County Agricultural Society will be held at the Arcade House, Rochester, on Wednesday, the 4th of January, at 11 o'clock, A. M., when the premiums will be awarded on Roots, Grain and Field Crops, and officers will be elected for the ensuing year.

Competitors for premiums on crops are requested to be particular in making out their statements and certificates—as required by the law of the state—(see the Sept. No. of the current vol. of the Farmer,) and it is very desirable that the claims and certificates be handed to the President or Secretary as early as the 1st of January.

Range of Thermometer for the month, 43 deg.

The fall of rain for the month of Oct. 2.20 inch.

Mean Temperature of " 15.42, 42.31 deg.

" " " 14.41, 44.46 "

" " " 18.10, 47.23 "

Remarks on the Weather from October 26th to November 25th.

Oct 26th, slight showers this afternoon; 28th, frost this morning; 29th, Indian summer commences—continues to the end of the month.

Nov. 3d, severe frost this morning—wild geese seen; 6th, Indian summer continues—it has been very fine for several days; 8th, commenced raining but subsiding about 11 o'clock and continued, rainy through the day; 9th, rainy this morning, snow this afternoon, first this autumn; cleared off at sunset; 10th, commenced raining about noon; 15th, pleasant and warm early in the evening—Ther. 46; rain, wind, snow and frost during the night; 19th, snow storm last night, with high wind; 20th, high wind, with snow squalls; 21st, snow last night. The week ending Nov. 24th, has been very cold and windy—much colder than the corresponding week of last year. The navigation on the Erie canal has closed during this week.

Winter seems to have commenced quite early: Nov. 23d, at the rising of the moon this evening between 8 and 9 o'clock, there appeared a cold of 15 degrees in length, as I judged, above, of remarkable brightness.

ROCHESTER SEED STORE AND SEED GARDEN.

NEW ARRANGEMENTS.—C. F. CROSMAN having purchased the entire business and effects of the Rochester Seed Store, desires to inform the Agents, Advertisers, and all who may wish to patronize the establishment, that he is now bringing in from his large seed fields on Abolus street, a complete assortment of such seeds as are best raised in this climate, and the will import from the first seedsmen in Europe and elsewhere, such kinds as are better raised in other climates. And seeds of doubtful value will be thoroughly tested by sowing, and none offered for sale that such as can be warranted genuine. The proprietor is fully aware that his large price is the consequence of the quality and purity of his seeds, and he trusts that his customers will be satisfied with the quality of his seeds in a manner that will prove satisfactory to the public.

Rochester, Oct. 1.

C. F. CROSMAN.
